## **01.1 PROBLEM FIELD**

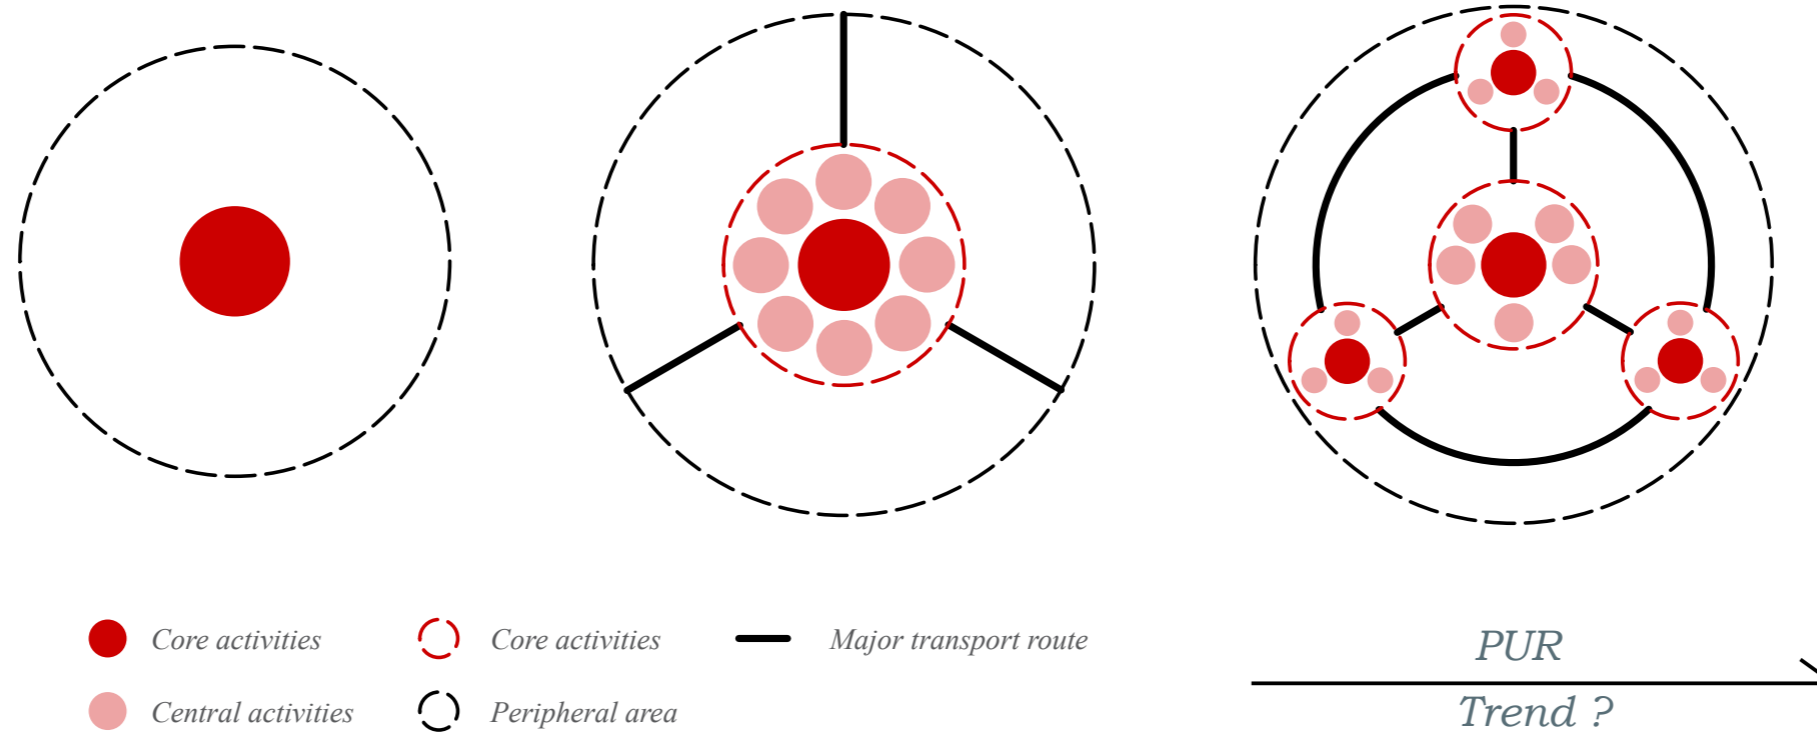

*BATTLE OF MITIGATING THE NEGATIVE EFFECT  
OF URBANISATION*

01.1 PROBLEM FIELD

*Circular Economy*

*Urban Metabolism*

*Polycentric Urban Structure*

*Provides Physical Platform*

KNOWLEDGE GAP

EMPIRICAL EVIDENCE

## 01.2 PROBLEM STATEMENT:

*INTEGRATED RESEARCH BETWEEN  
CIRCULAR ECONOMY AND URBAN SPATIAL STRUCTURE*

## 01.2 PROBLEM STATEMENT

*The main aim of this project is to investigate an approach to integrate the study of CE with urban spatial structure, then form a tool to assist the procedure of decision making by analysing empirical data.*

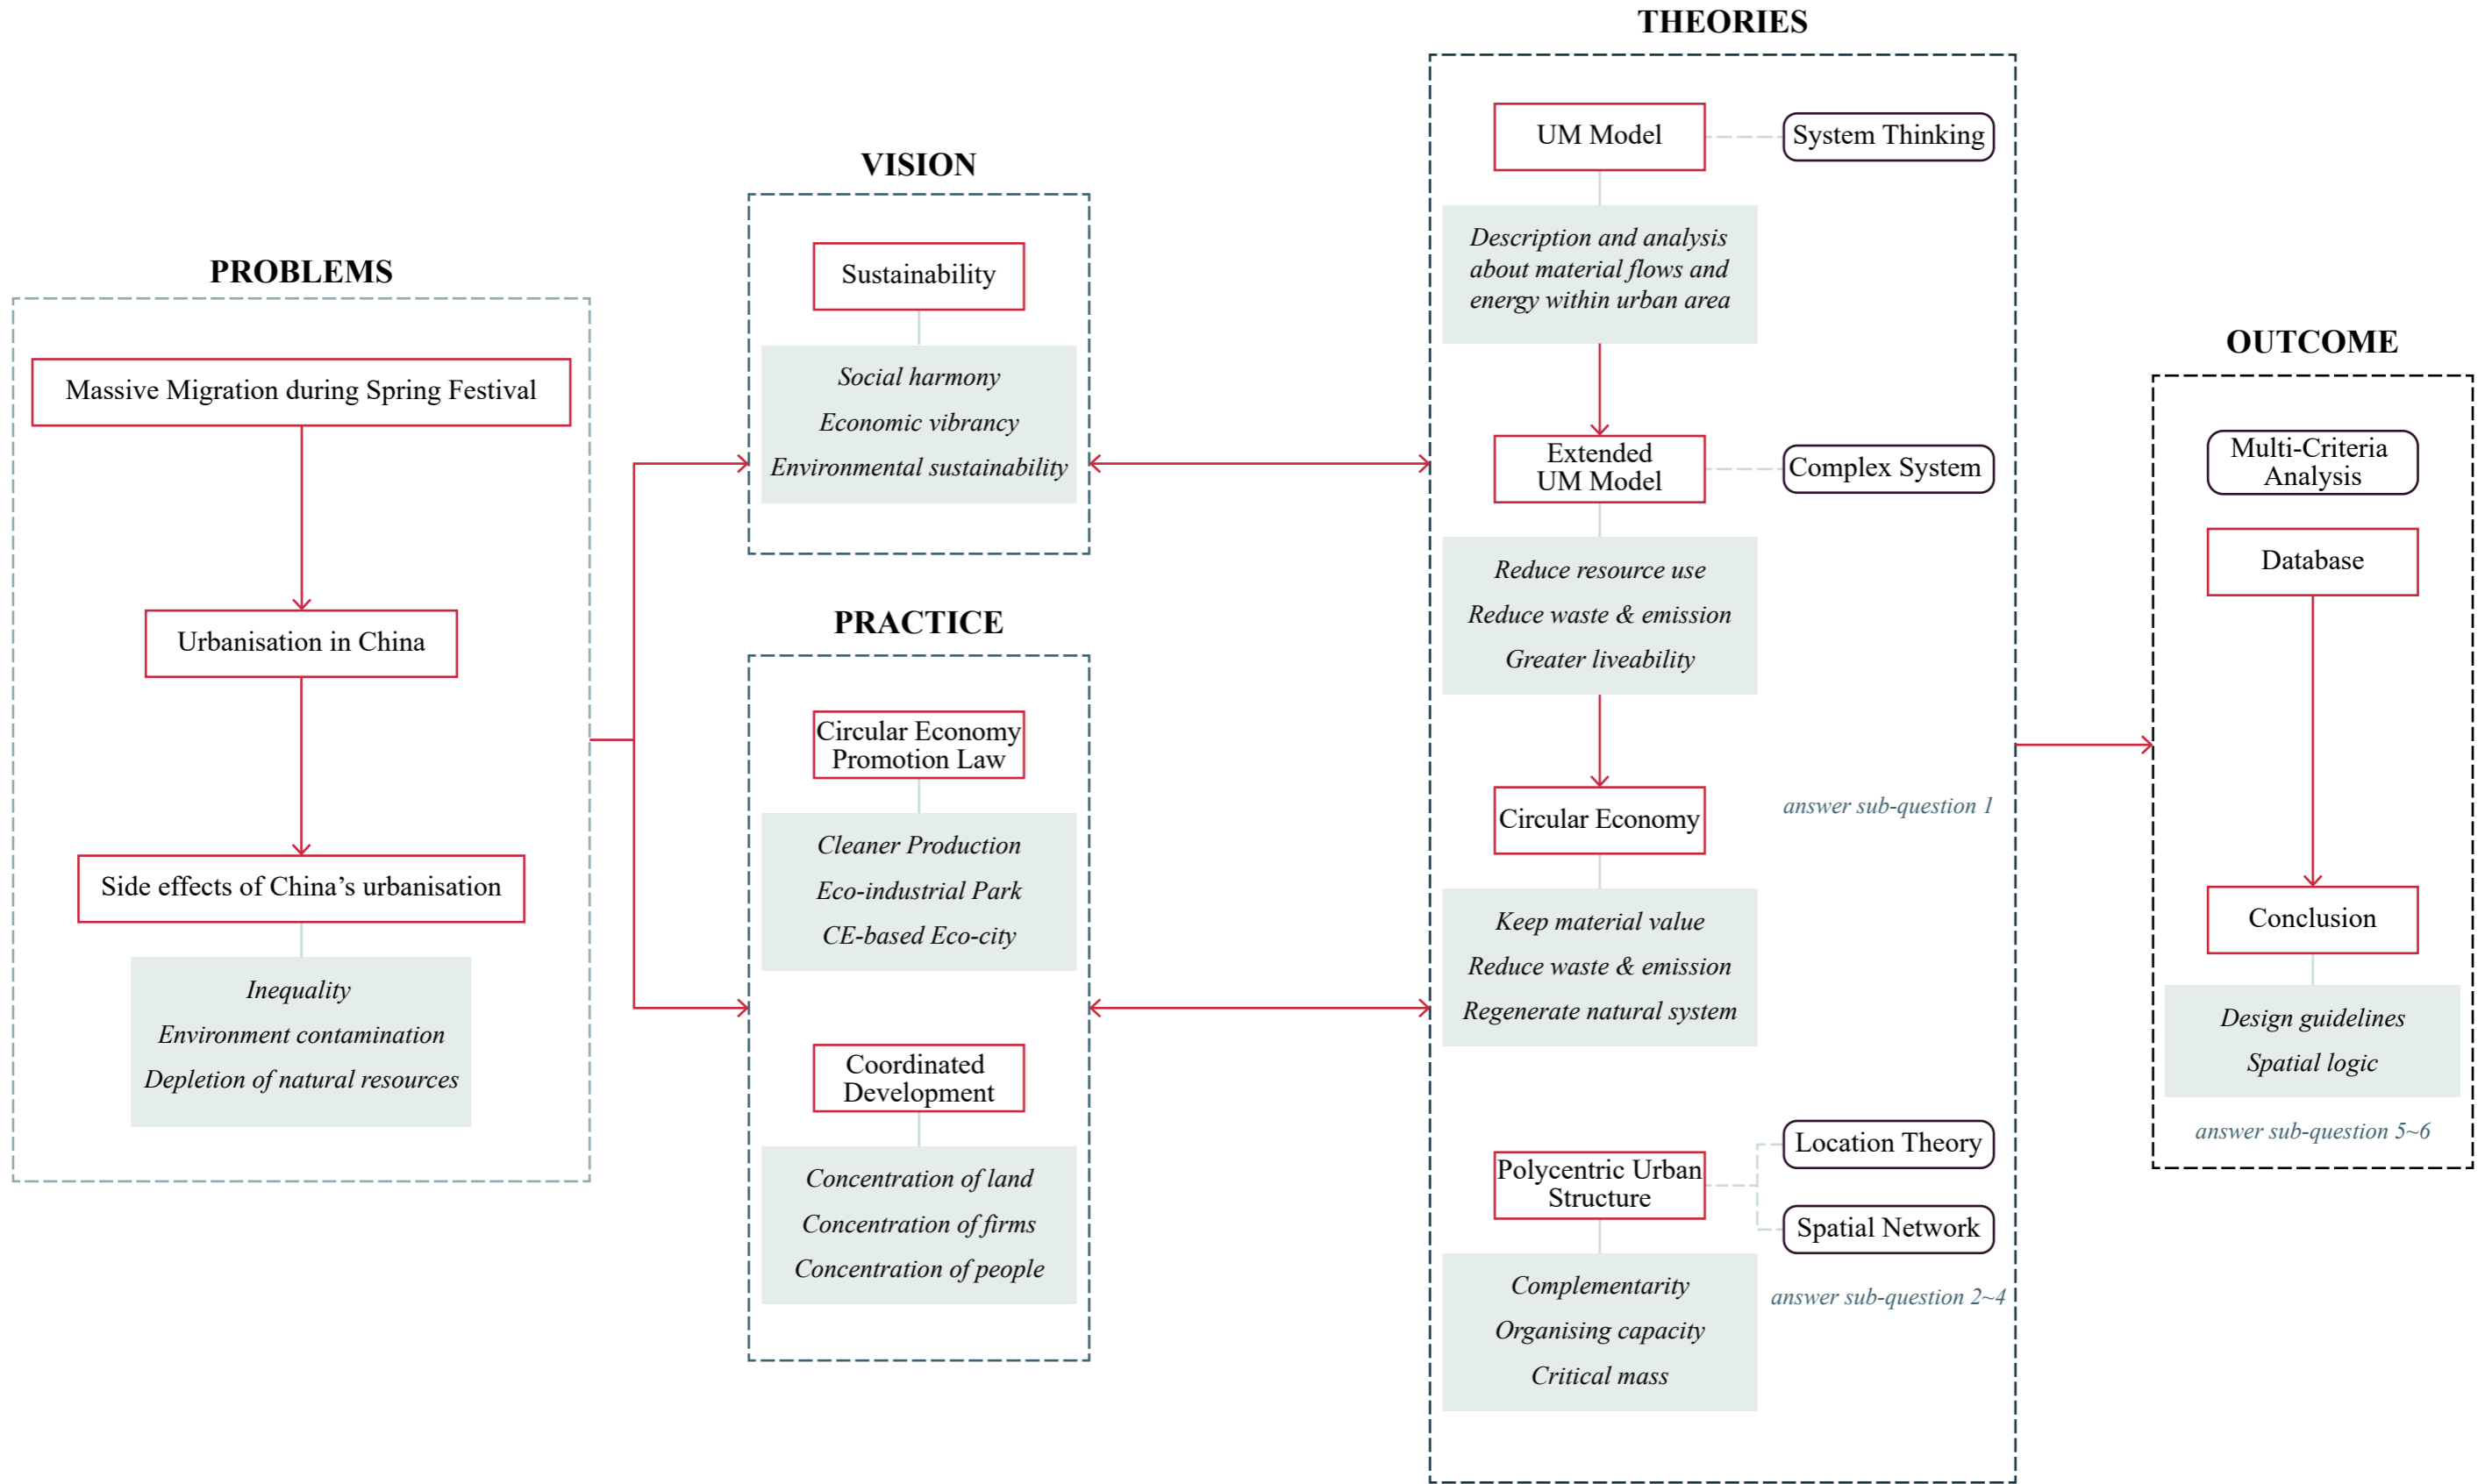

### 01.3 RESEARCH QUESTION:

### 01.3 RESEARCH QUESTION

*Which spatial structure has more potential to facilitate urban symbiosis? What is the most compatible approach for allocating associated facilities in the metropolitan area?*

## 01.4 THEORETICAL FRAMEWORK

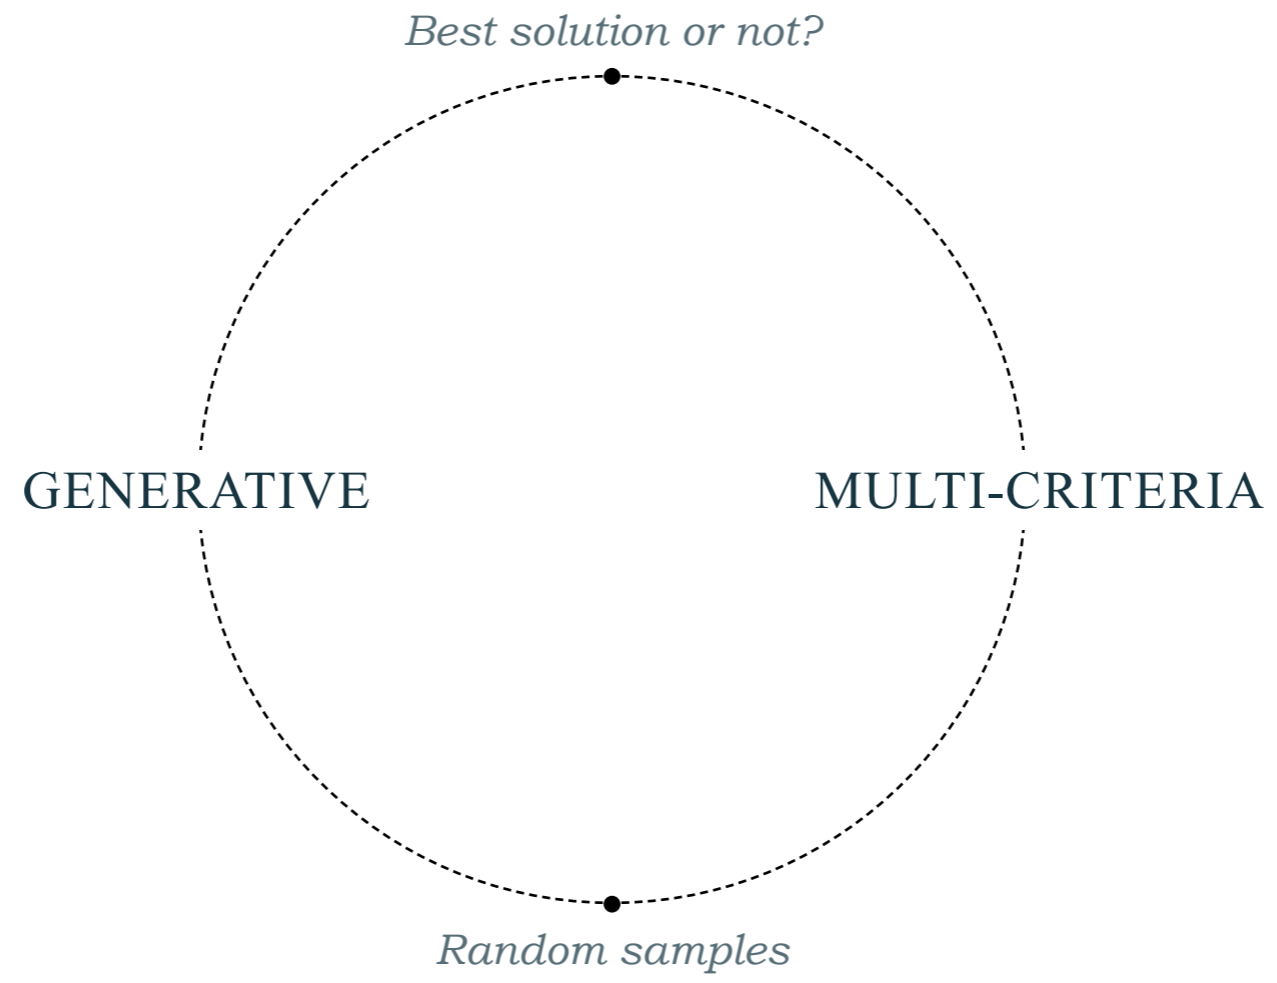

## 01.5 RESEARCH APPROACH

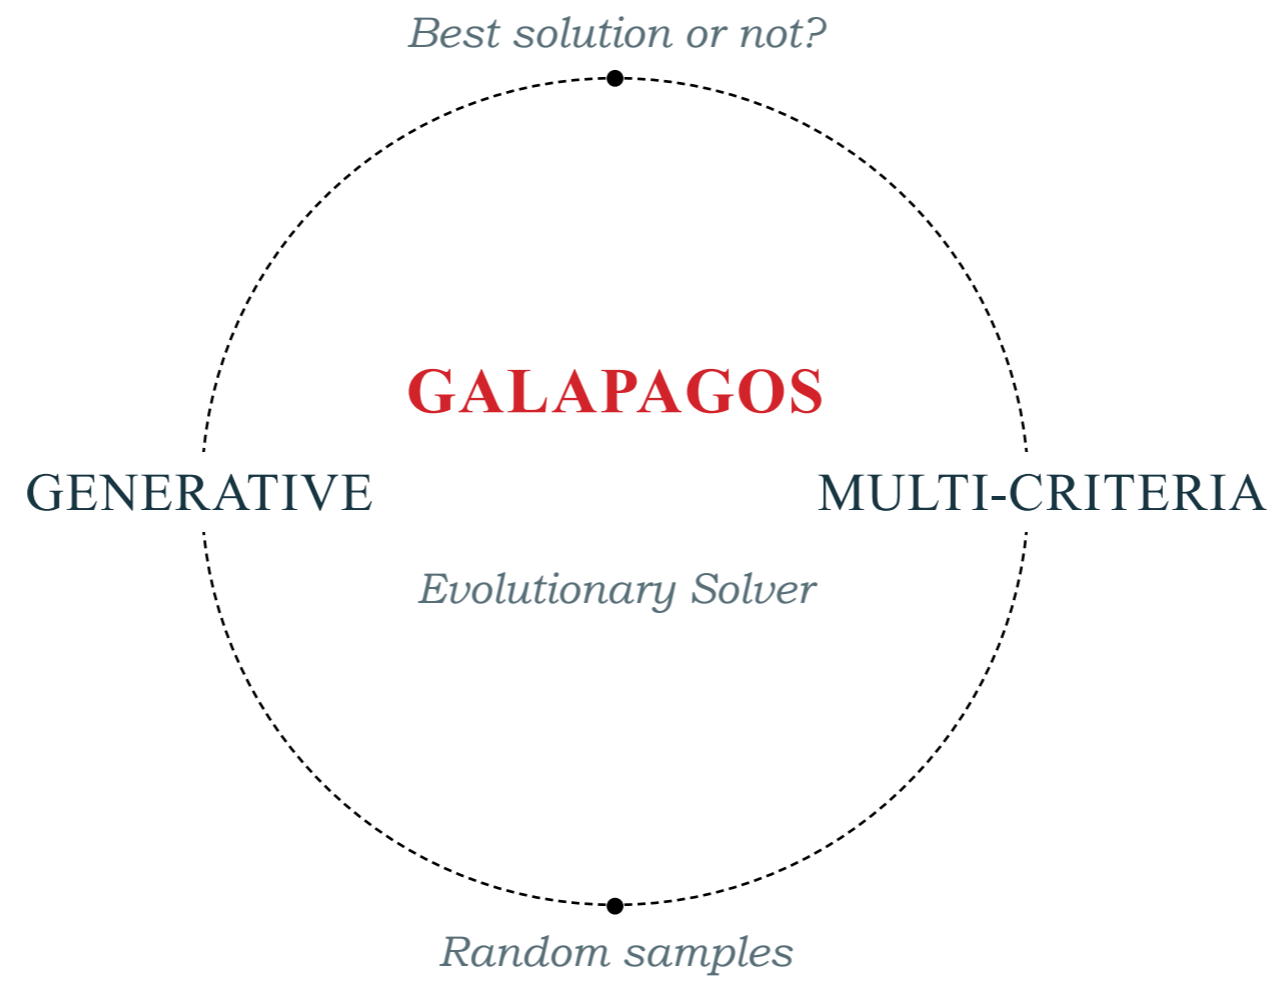

*Generative multi-performance design system*

*Diagram of generative multi-performance design system

SPATIAL MODEL

## **03 ABSTRACT MODEL**

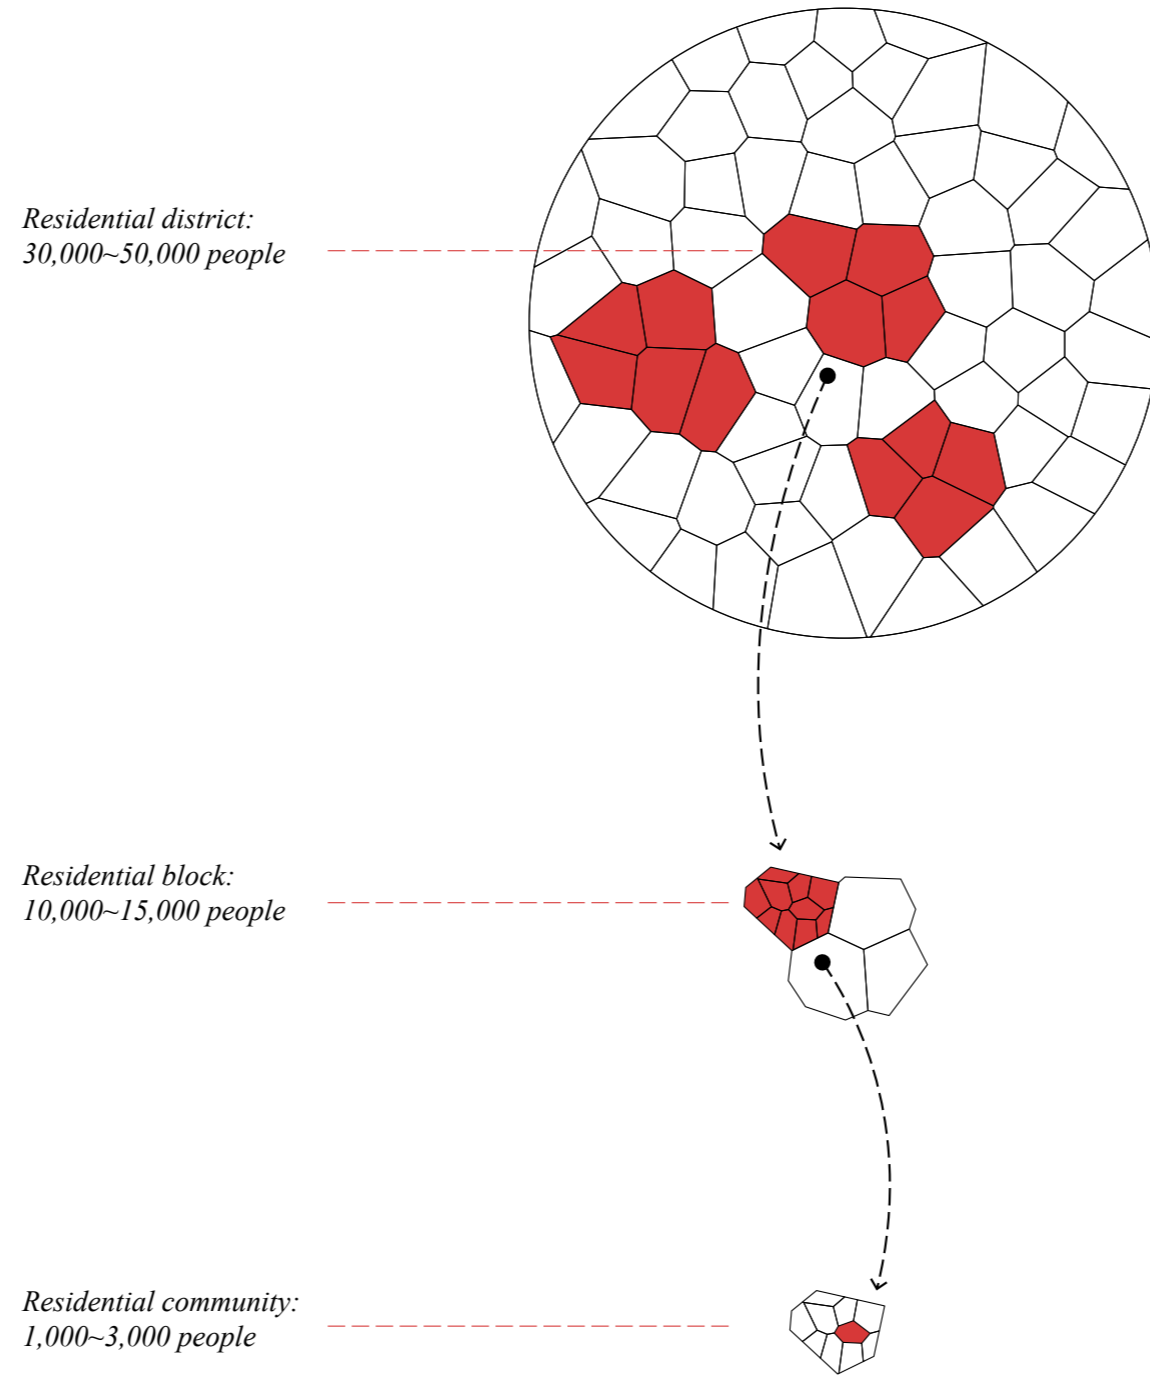

### 03.1 PREREQUISITE OF MODEL

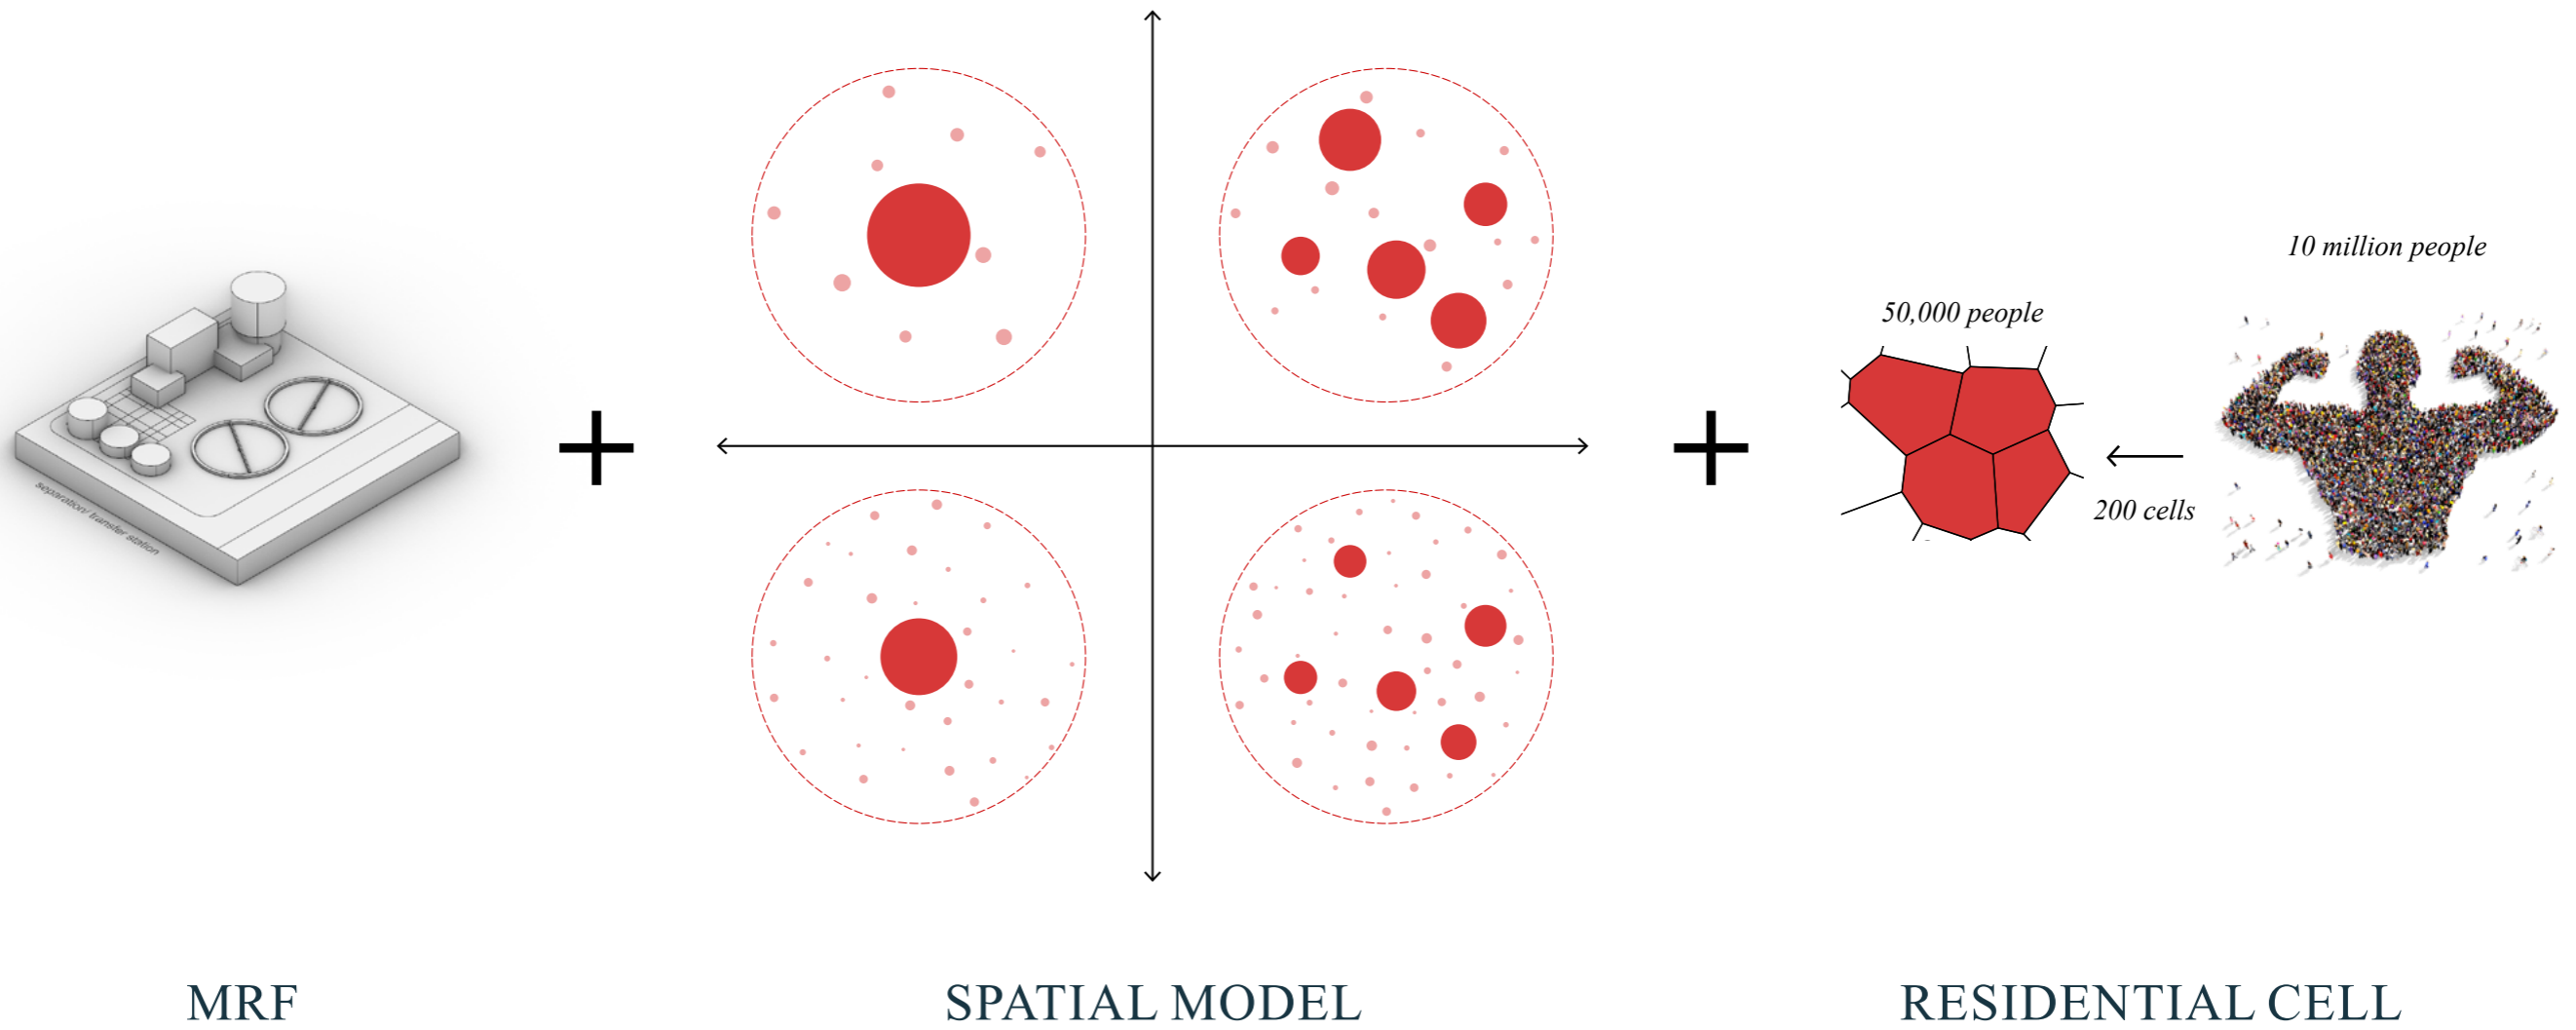

*Metropolis with 10 Million people*

*Population: 10 million  
Area: 100km\*100km  
MSW: 1.2 kg/person/day  
Total MSW:12000 tonnes/day*

*Three types of Chinese residential area*

## 03.2 SPATIAL DEMAND CONE SIMULATION

*Density and Land Price: Spatial demand curves*

Source: spatial demand curves(Made by author based on the location theory by Alonso (1964))

*Electric field simulation*

*A built-in function in Grasshopper*

ANSWER

*Theoretical basis : Gravity Cities*

Source: Angel and Hyman (1972)

*There are exist two places, which are numbered by  $i$  and  $j$ . According to first law of geography (Tobler, 1973), the two places are attracted to each other. The interaction between the two places can be measured with the gravity model*

$$I_{ij} = G \frac{P_i P_j}{r_{ij}^b},$$

*where  $I_{ij}$  denotes the gravity between places  $i$  and  $j$ , which can be represented with the quantity of the flow from one place to the other,  $P_i$  and  $P_j$  are the "mass", which can be reflected by the population size of places  $i$  and  $j$ ,  $r_{ij}$  is the distance between  $i$  and  $j$ ,  $G$  refers to a proportionality coefficient, and  $b$ , to the distance exponent.*

*Electric field definition*

*Electric field definition*

$$\text{Electric Field Strength} = \frac{\text{Force}}{\text{Charge}}$$

$$E = \frac{F}{q}$$

$$F = \frac{kqQ}{d^2} \quad \text{-----} \rightarrow \quad I_{ij} = G \frac{P_i P_j}{r_{ij}^b}$$

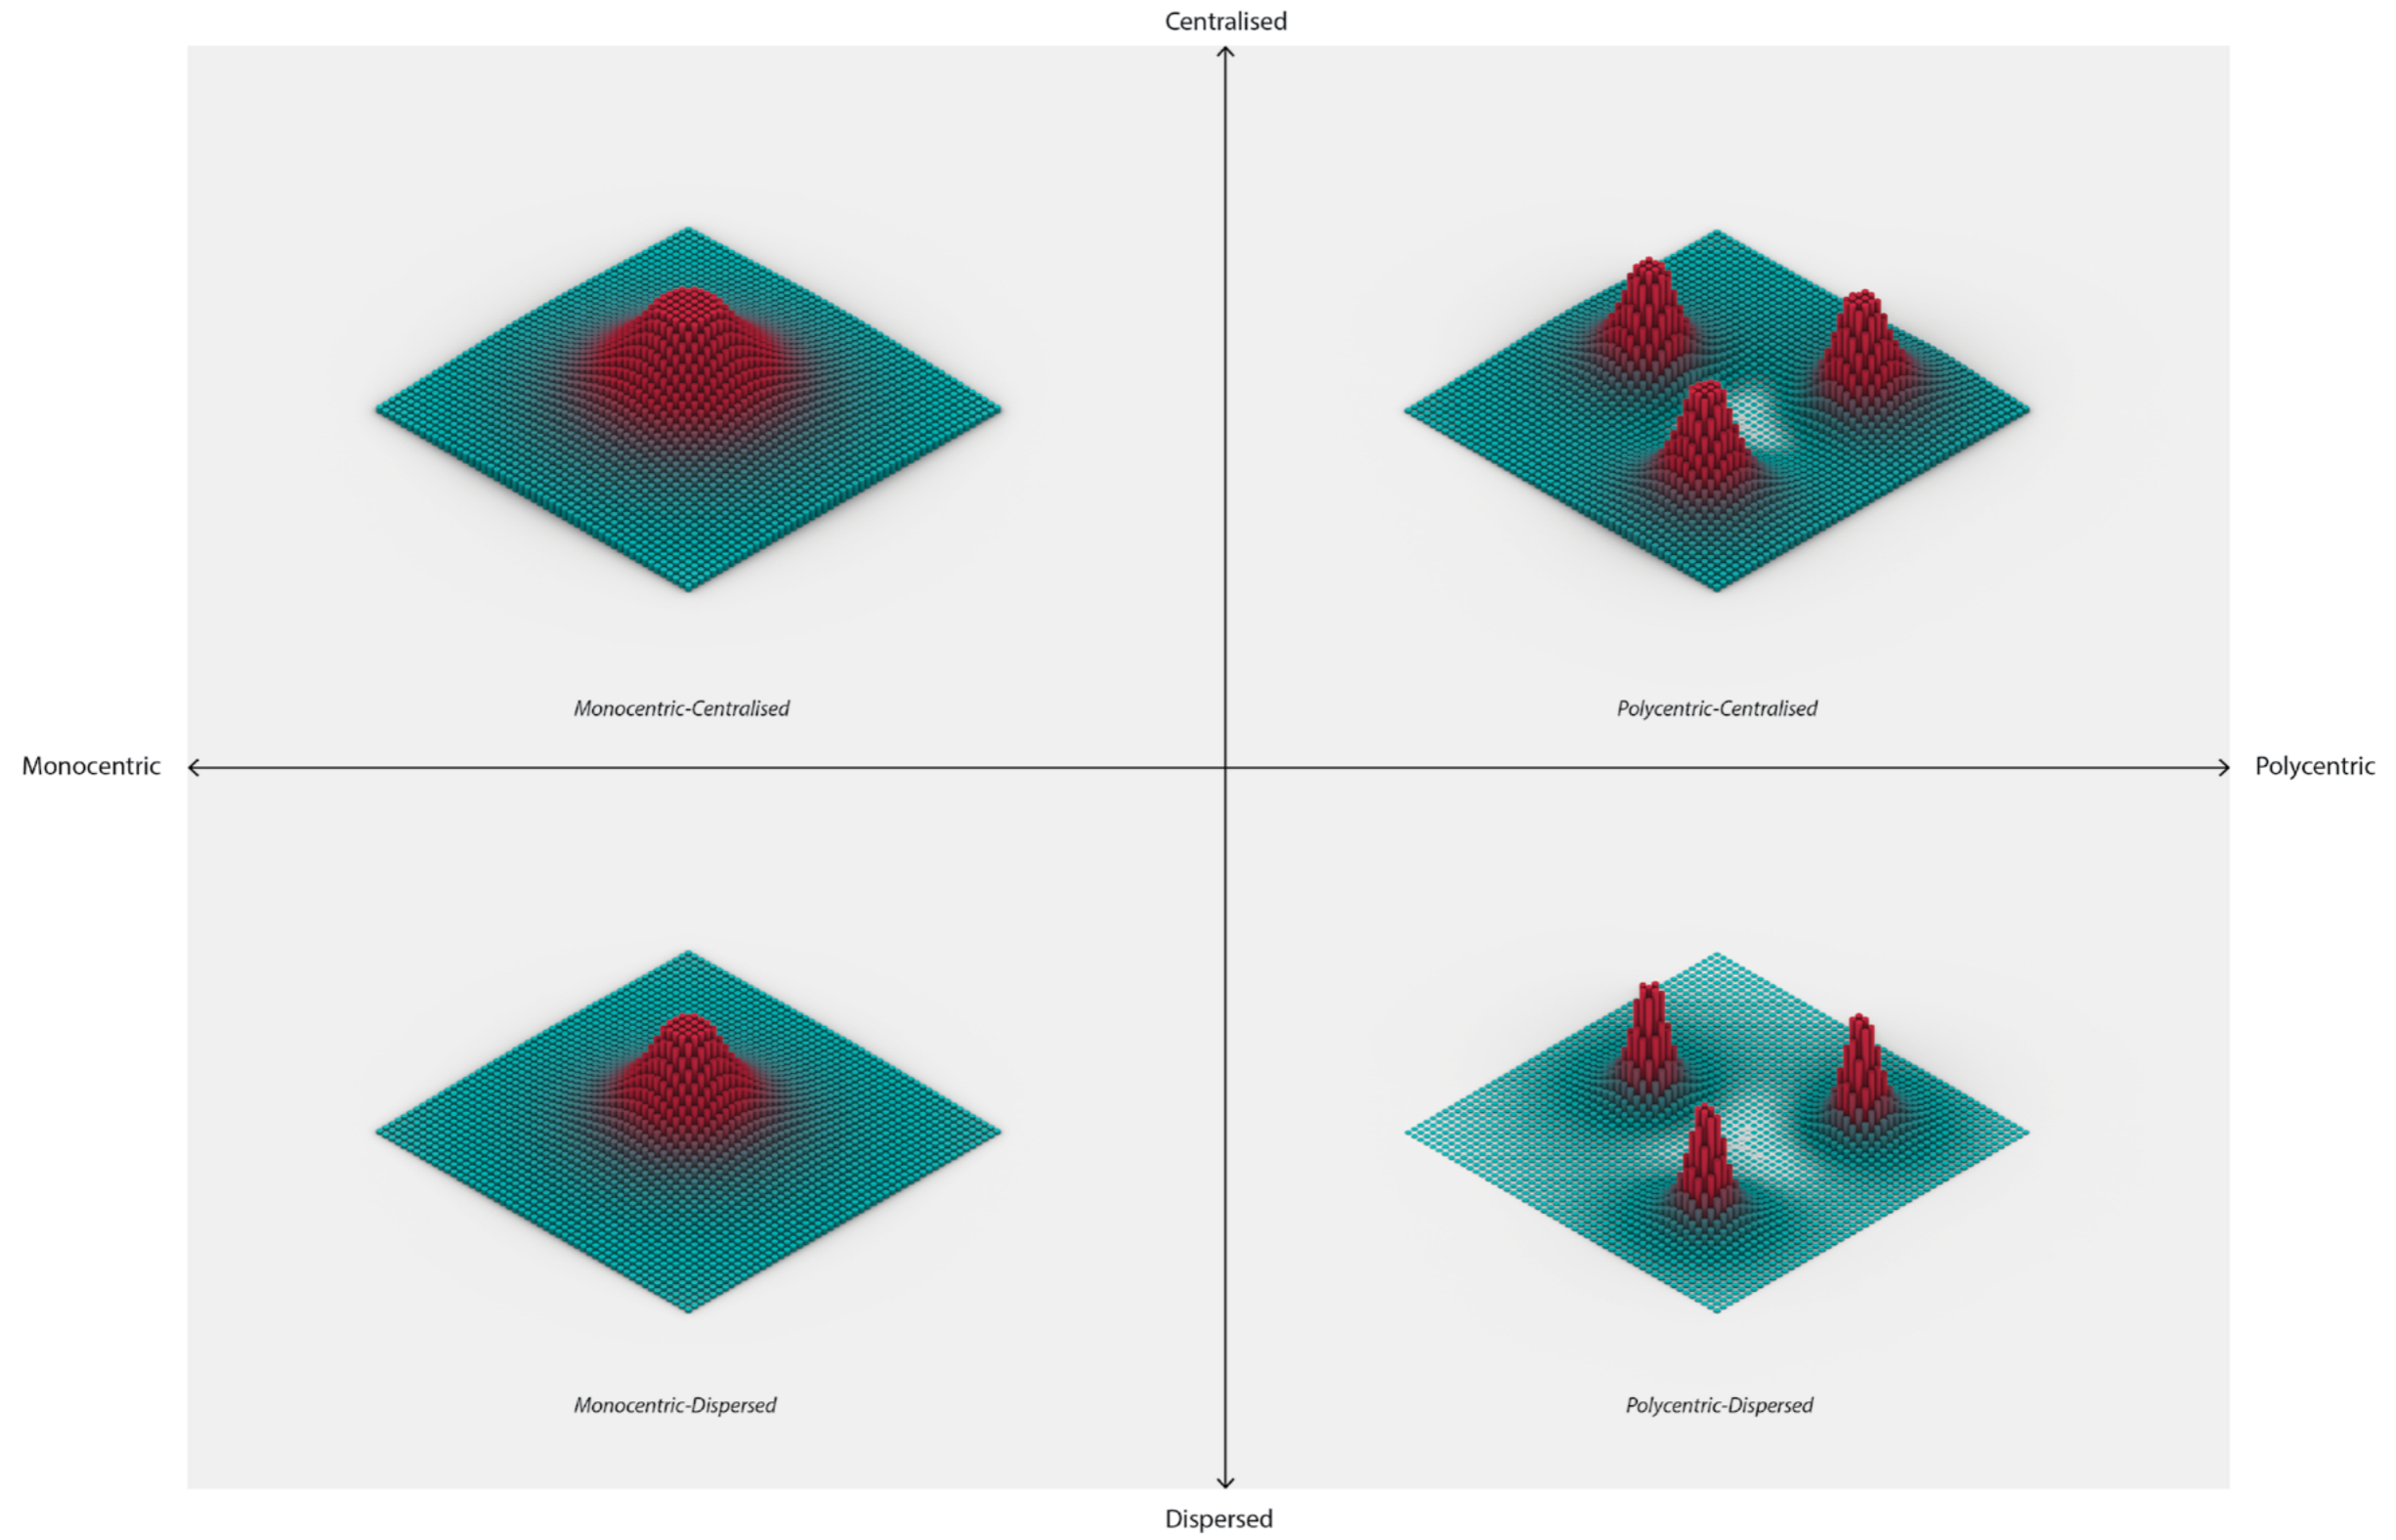

where  $d$ =separation distance between charges (meters)

$$E = \frac{F}{q} = \frac{kQ}{d^2} \quad \text{-----} \rightarrow \quad \begin{array}{l} \text{Influence power of urban centre} \\ \text{Distance to urban centre} \end{array}$$

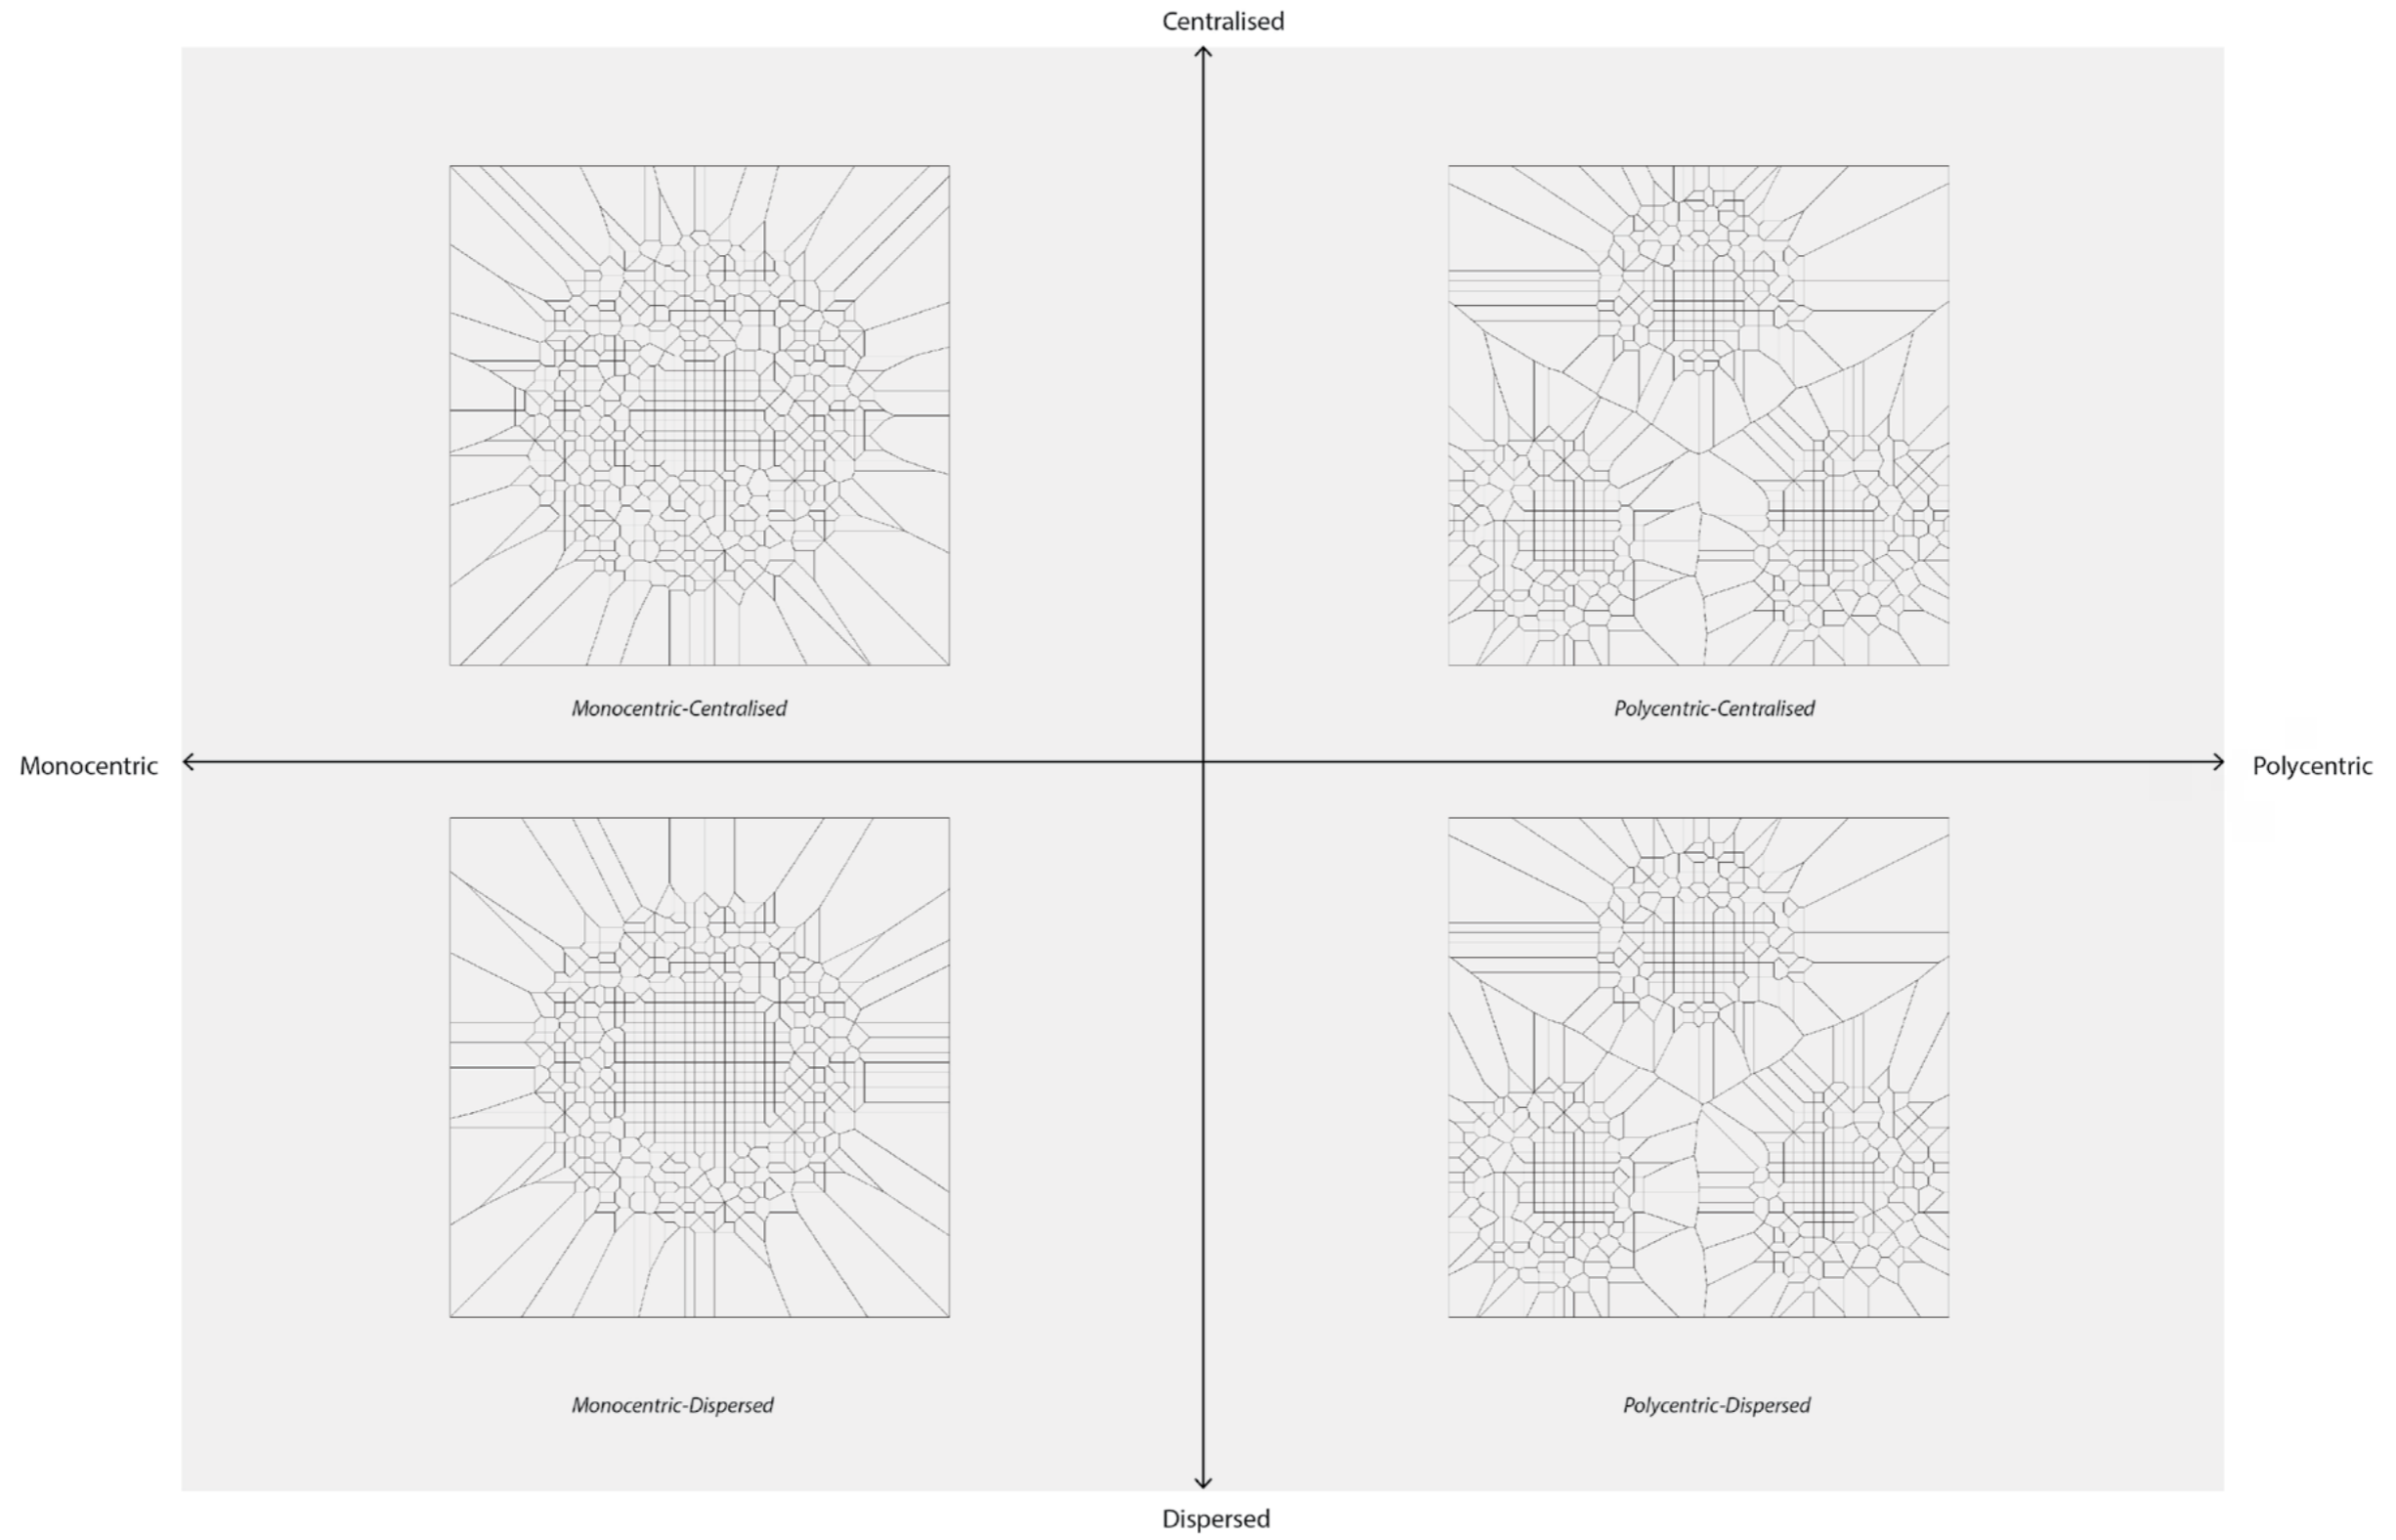

*An inverse square law*

## 03.4 DISTRIBUTION OF MATERIAL RECOVERY FACILITIES

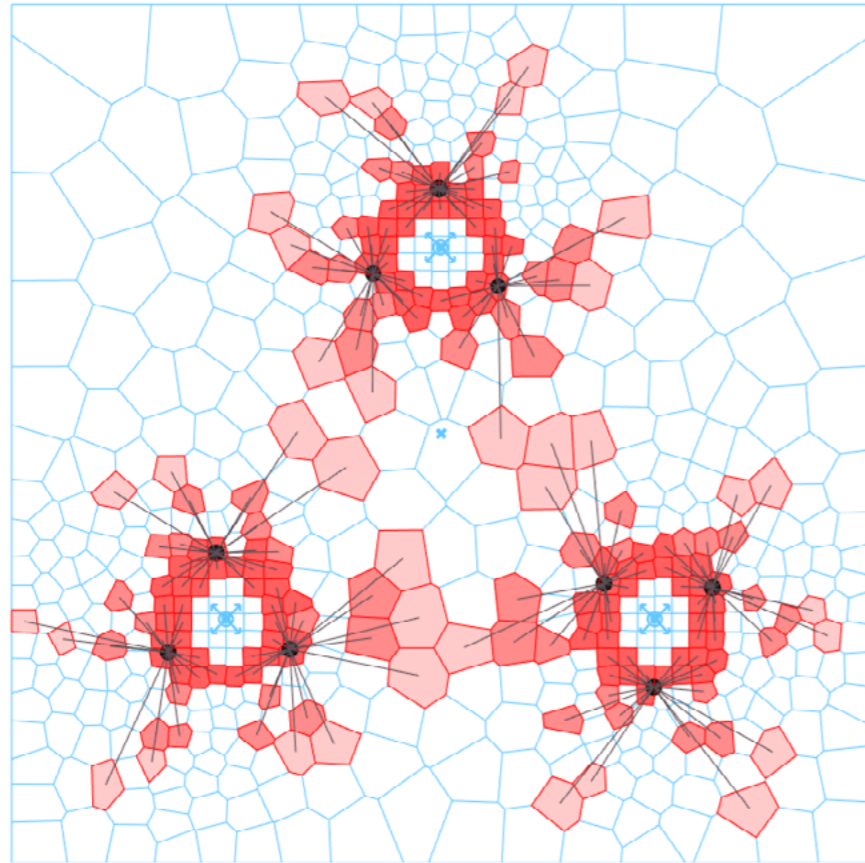

03.4 DISTRIBUTION OF MATERIAL RECOVERY FACILITIES

Capacity of MRF ( TPD, means Tons/Day)

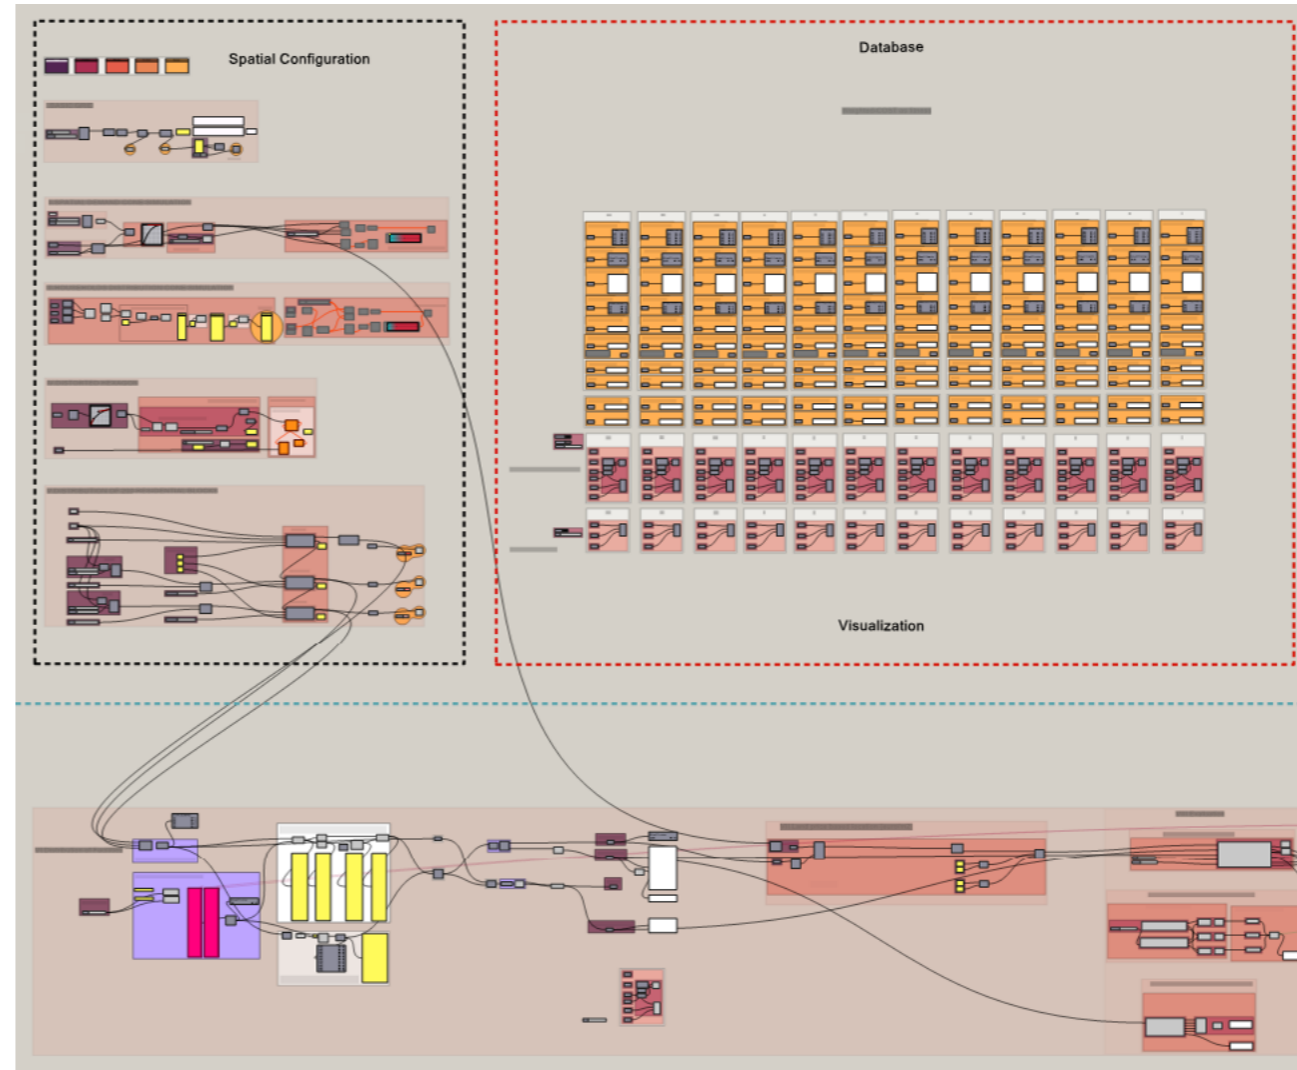

Visualisation

Script

First try: Fitness is minimised total distance for all the connections (ignored the influence of land price)

### 03.5 RESULT FOR FIRST DISTRIBUTION

*Distributing MRF in Monocentric-centralised model*

1. Average capacity: 200TPD (60 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

4. Average capacity: 1000TPD (12 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

2. Average capacity: 400TPD (30 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

5. Average capacity: 1500TPD (8 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

3. Average capacity: 660TPD (18 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

6. Average capacity: 3000TPD (4 facilities)

*linkages between facilities and serverd cells*

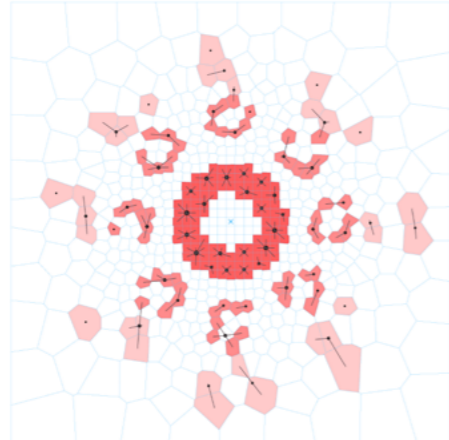

*'minimal spanning' among entire cells and plants*

*Distributing MRF in Monocentric-dispersed model*

1. Average capacity: 200TPD (60 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

4. Average capacity: 1000TPD (12 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

2. Average capacity: 400TPD (30 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

5. Average capacity: 1500TPD (8 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

3. Average capacity: 660TPD (18 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

6. Average capacity: 3000TPD (4 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

*Distributing MRF in Polycentric-centralised model*

1. Average capacity: 200TPD (60 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

4. Average capacity: 1000TPD (12 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

2. Average capacity: 400TPD (30 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

5. Average capacity: 1500TPD (8 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

3. Average capacity: 660TPD (18 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

6. Average capacity: 3000TPD (4 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

*Distributing MRF in Polycentric-dispersed model*

1. Average capacity: 200TPD (60 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

4. Average capacity: 1000TPD (12 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

2. Average capacity: 400TPD (30 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

5. Average capacity: 1500TPD (8 facilities)

*linkages between facilities and serverd cells*

*'minimal spanning' among entire cells and plants*

3. Average capacity: 660TPD (18 facilities)

*linkages between facilities and serverd cells*

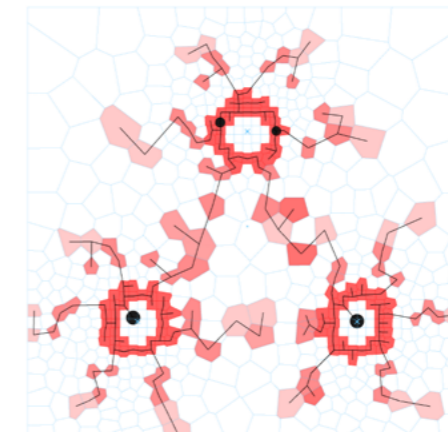

*'minimal spanning' among entire cells and plants*

6. Average capacity: 3000TPD (4 facilities)

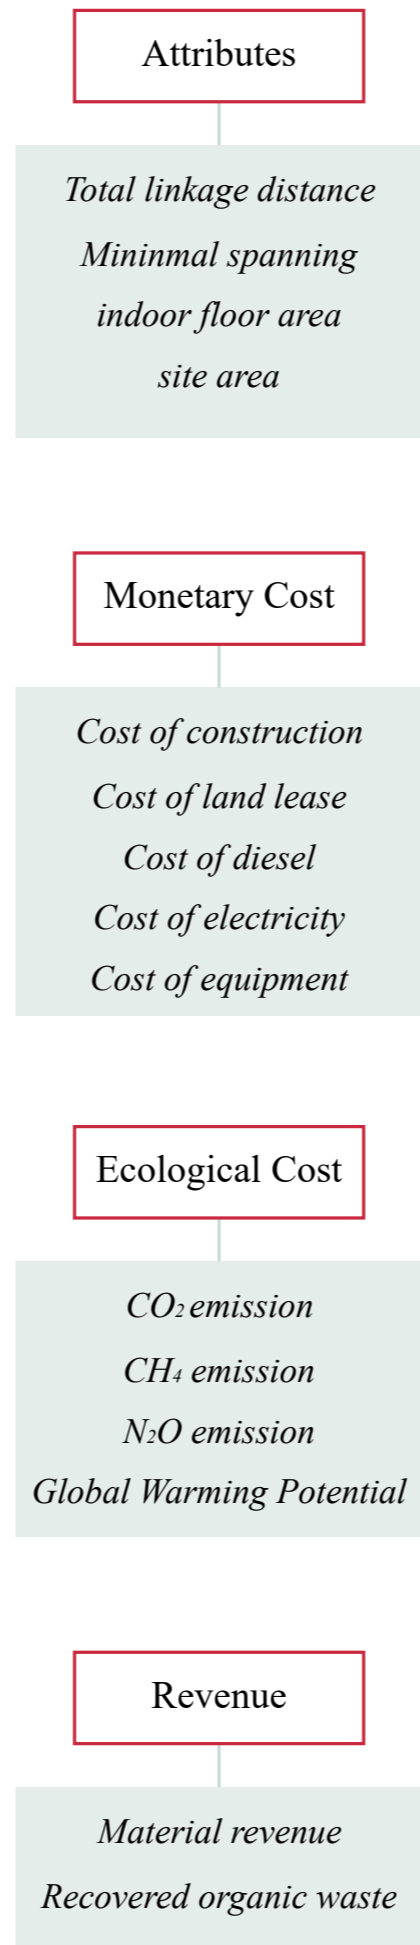

*linkages between facilities and serverd cells*

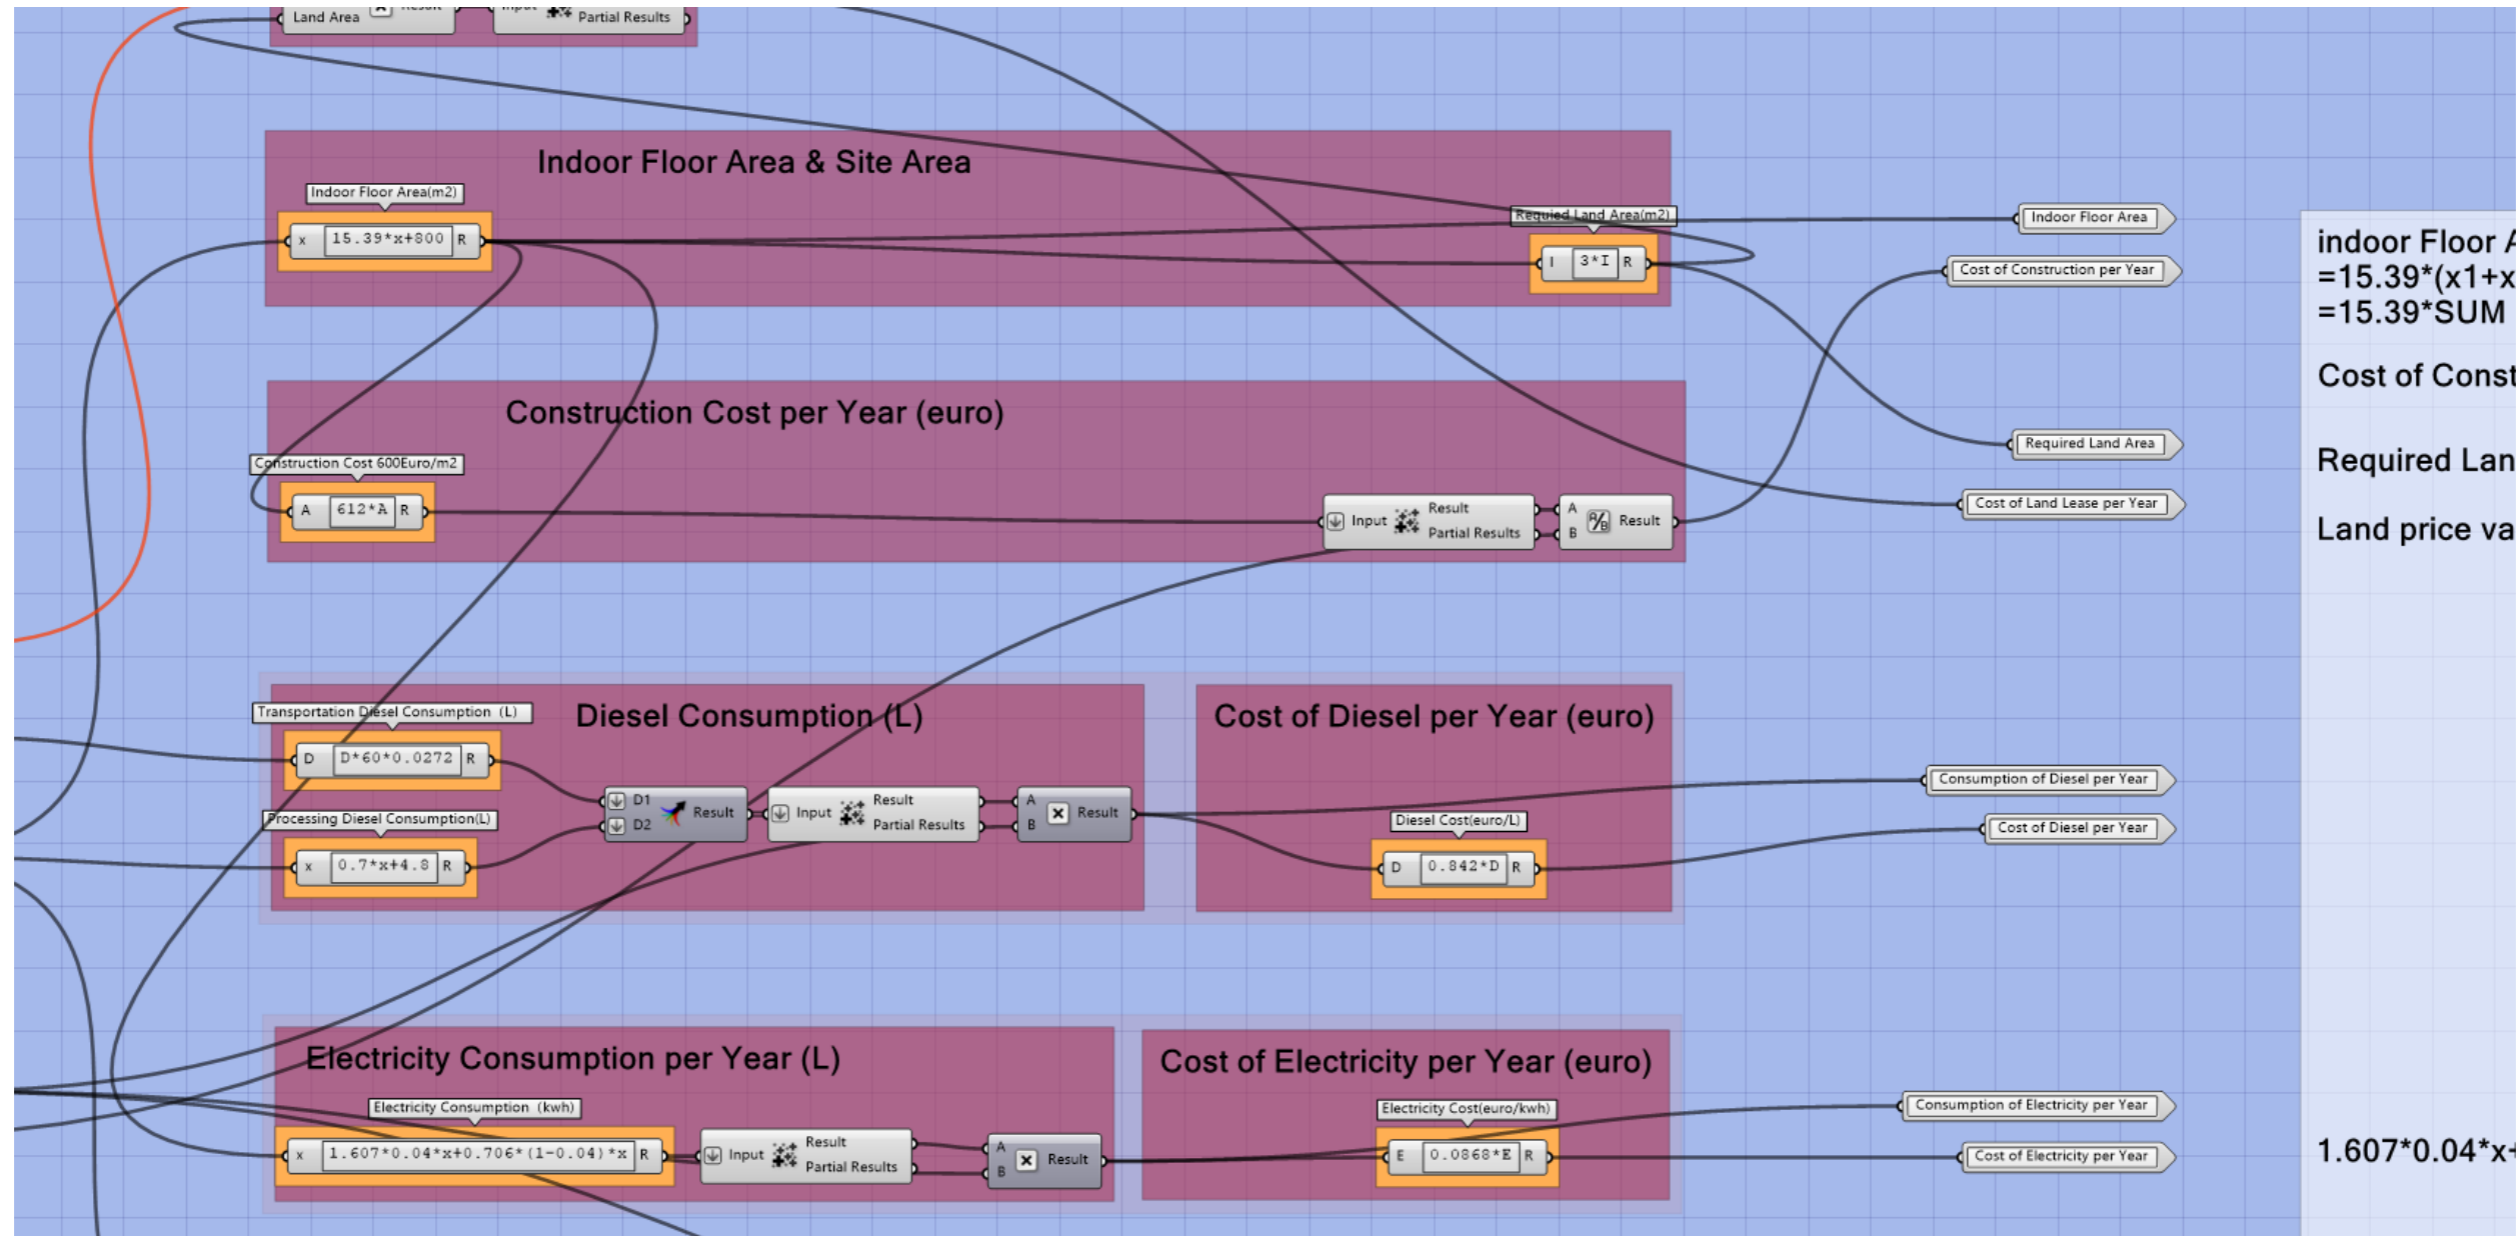

*'minimal spanning' among entire cells and plants*

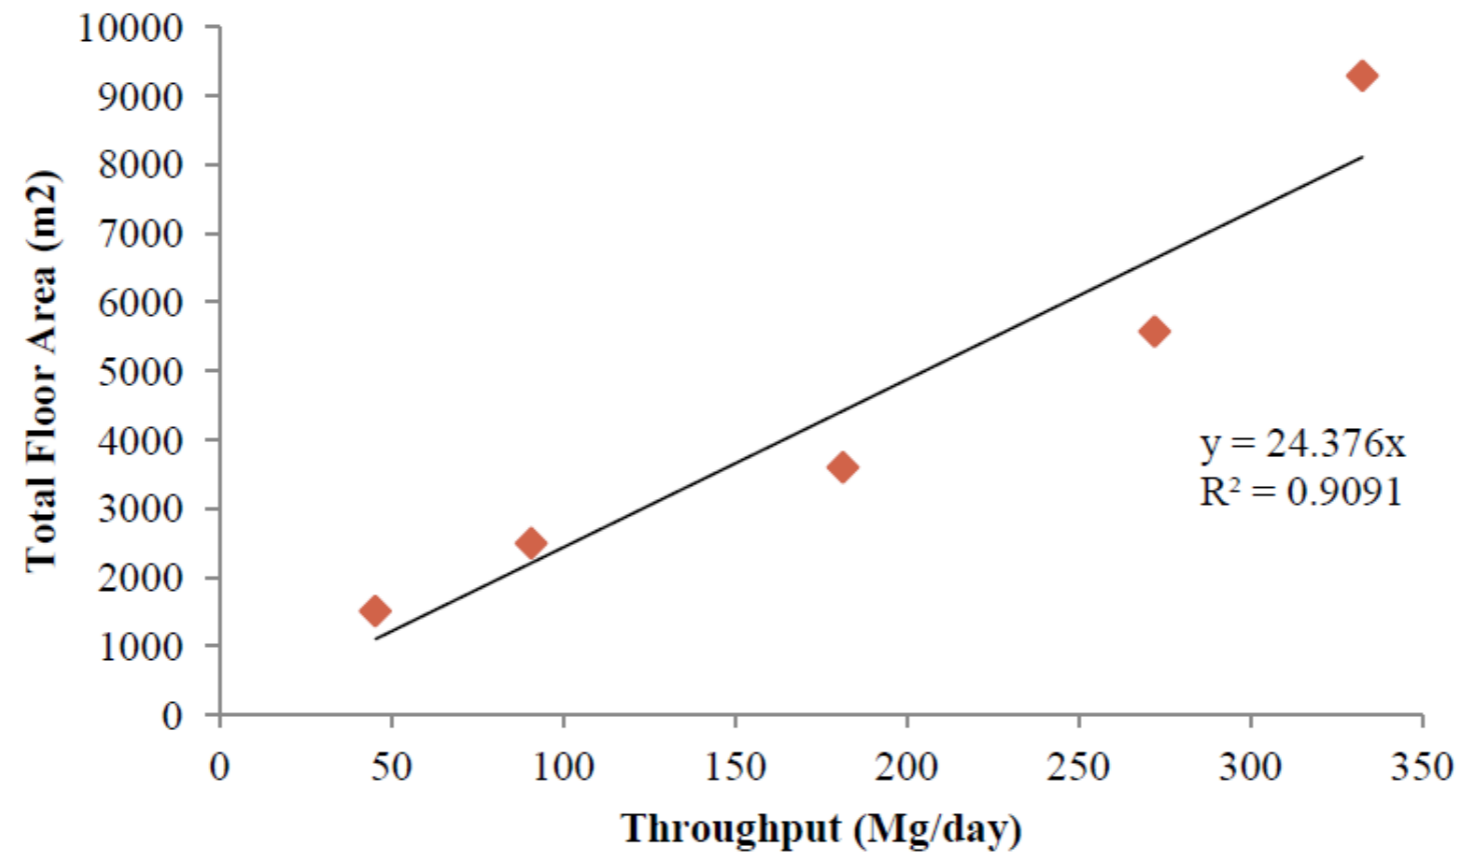

## 03.6 EVALUATION OF PERFORMANCE

*Script for all the caculations*

*Example: indoor area caculation*

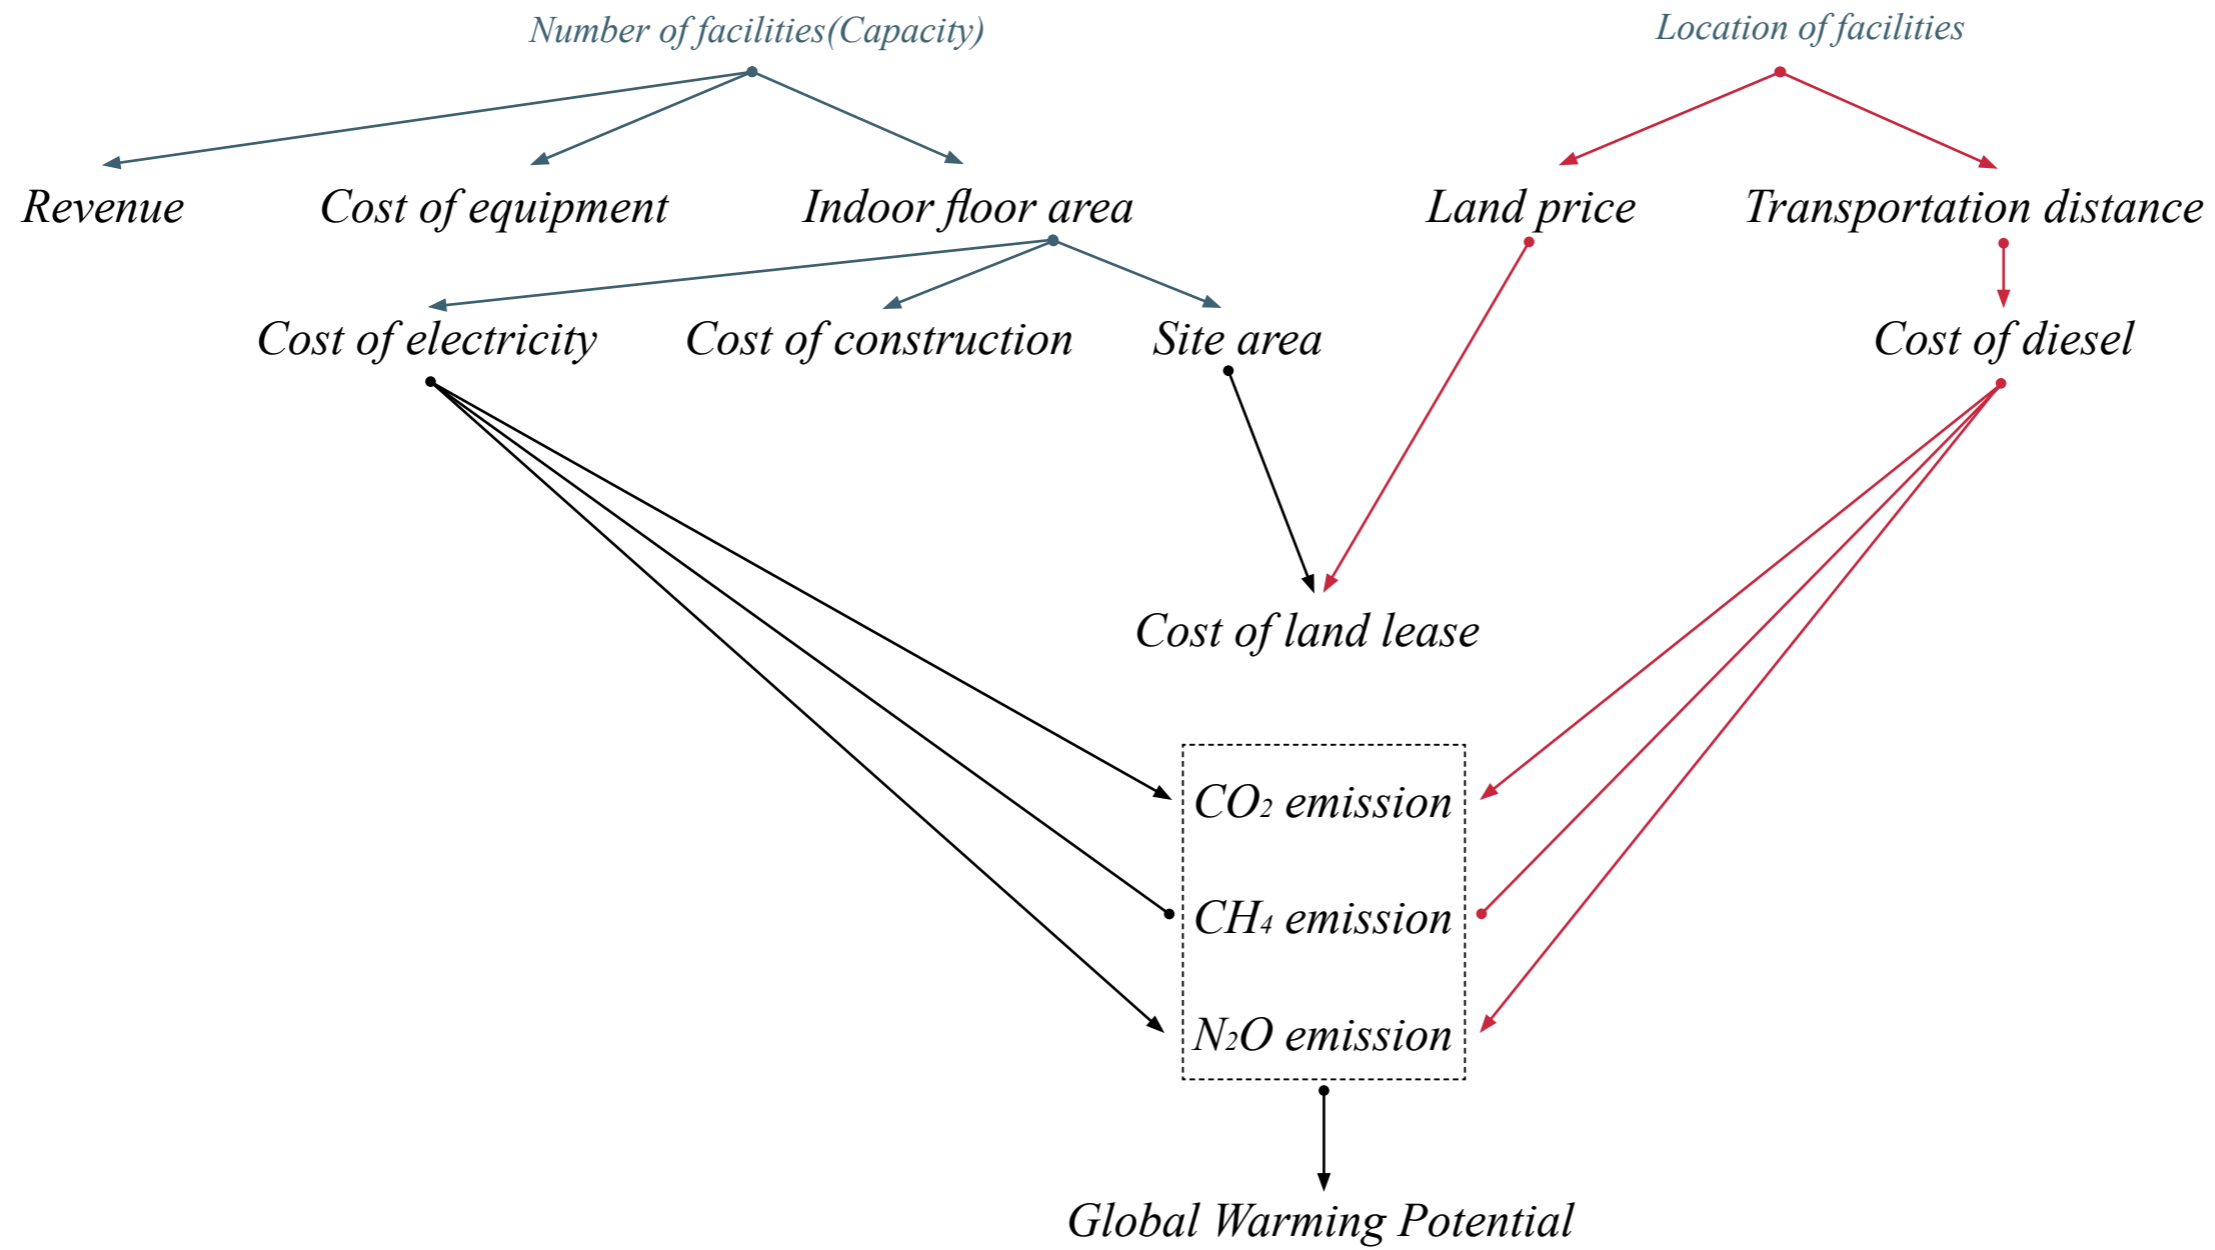

*Source: Combs, A. R. (2011). Life Cycle Analysis of Recycling Facilities in a Carbon Constrained World.*

$$y = 15.39x + 800$$

*Where y represents the needed total indoor floor area (m<sup>2</sup>), x is the total material processed per day, which is equal to the capacity (TPD) of the MRF.*

Hierarchy of all the results

## **04 RESULT AND ANALYSIS**

### **04.1 COMPARISON OF THE PERFORMANCE IN FOUR MODELS**

## 04.1 COMPARISON OF THE PERFORMANCE IN FOUR MODELS

This chart shows polycentric model has less total linkage distance, which can represent the transportation cost. With the increasing of the number of facilities, the total cost of transportation will reduce.

This chart shows the centralised model could use less infrastructure to cover all the cells and facilities. Within the centralised mode or dispersed model, polycentric dimension will require more distance to cover the whole territory.

This chart indicates that the polycentric dispersed model need the smallest amount of money for land lease while monocentric centralised model is most expensive. With the increase of facilities number, the land cost will rise slightly.

## 04.1 COMPARISON OF THE PERFORMANCE IN FOUR MODELS

Because the land cost and construction cost are the largest part of the total cost, with the percentage from 40% to 60%, the trend of total cost is similar to land cost. Again, monocentric model is the most costly form for allocating MRF.

This chart shows the Global Warming Potential, which can represent the ecological cost. Generally, the polycentric model generates more emissions due to the longer transport distance. When the number of facilities within the range from six to twelve, the all city will have lowest influence to the environment.

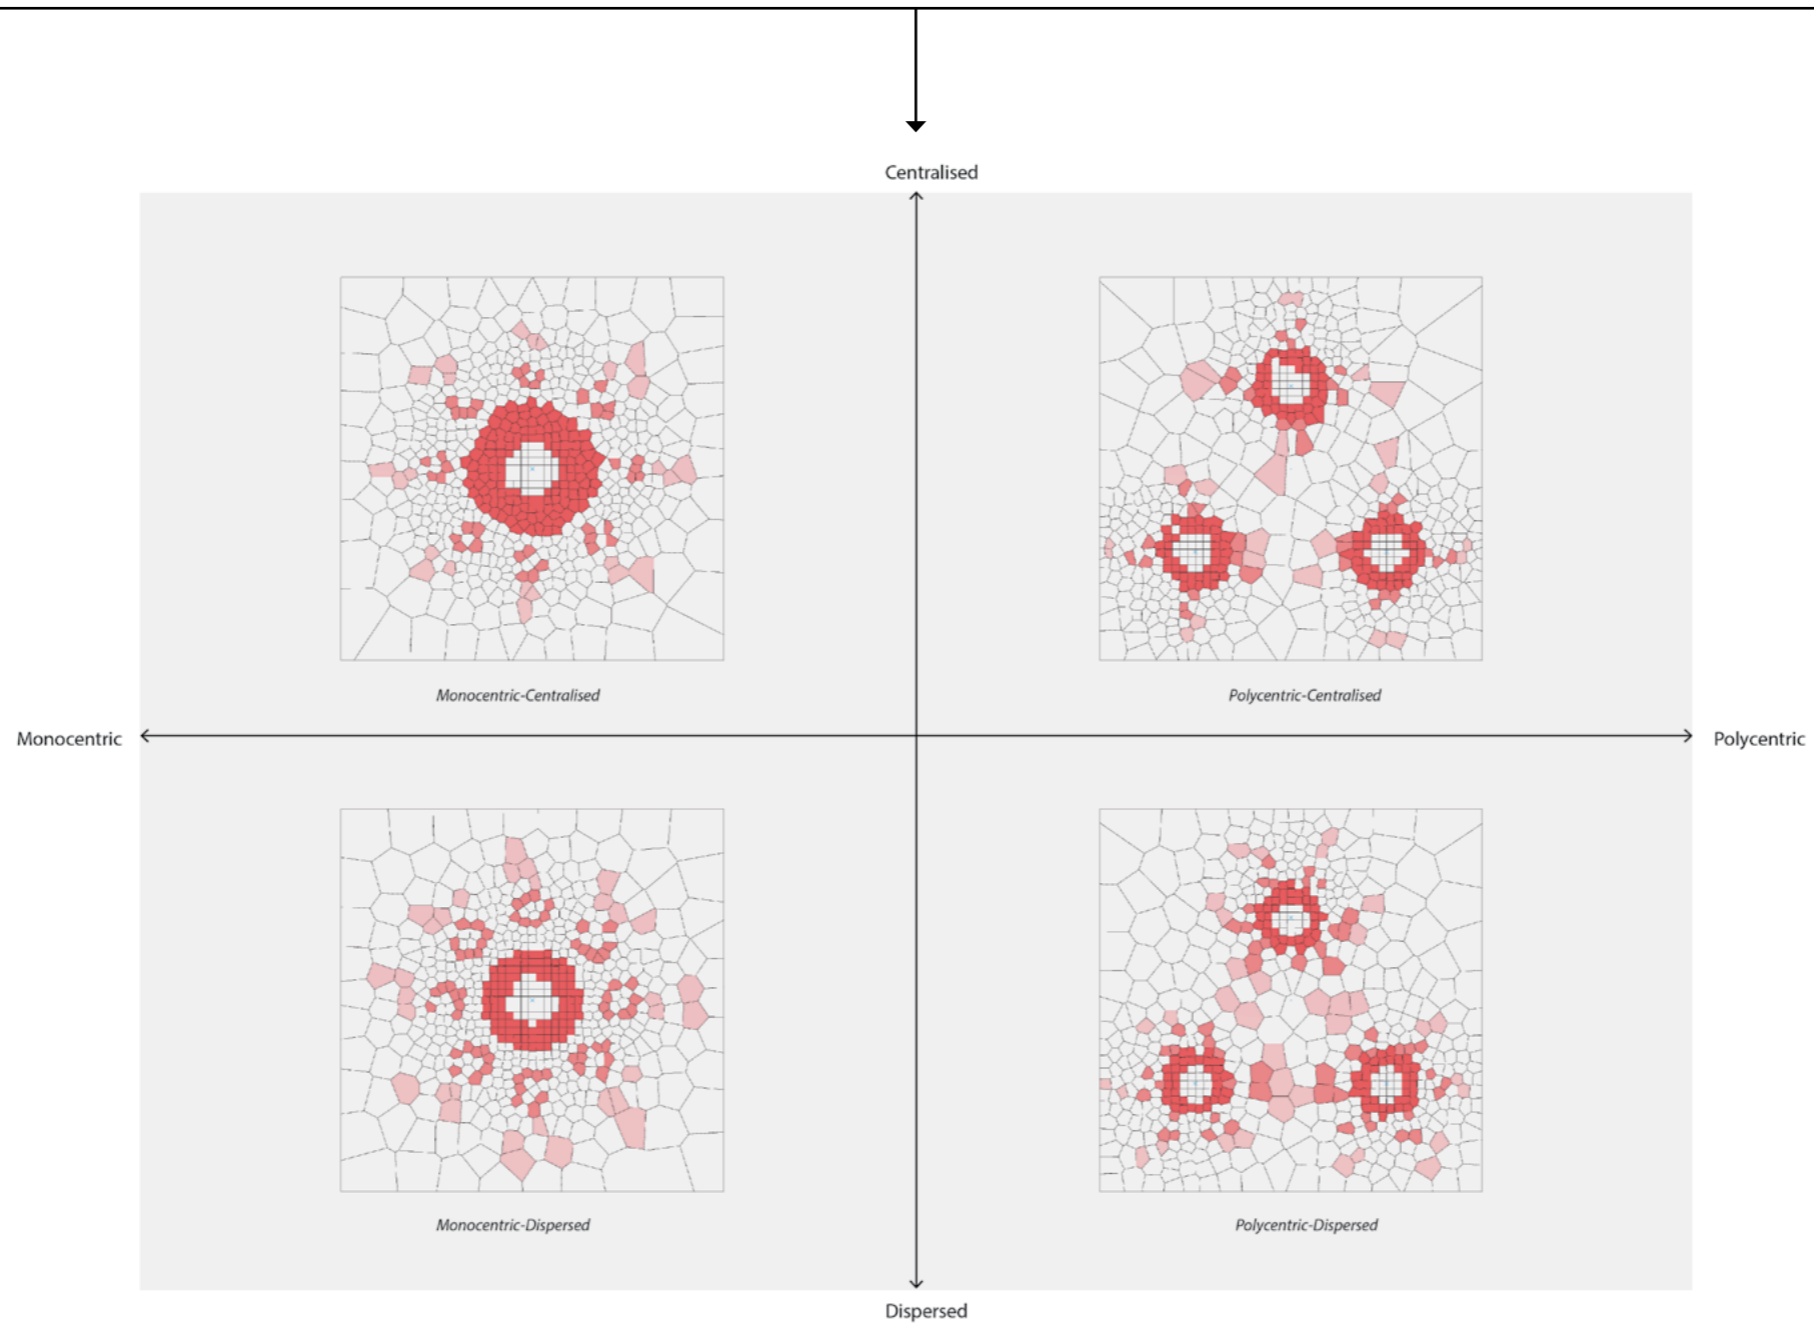

The ability of recovering the organic waste rarely influenced by the different spatial structures. By contrary, the collective efficiency heavily rely on the number of facilities. With the decrease of capacity, the efficiency of MRF will also decrease.

## 04.2 OPTIMISING THE DISTRIBUTION OF MRF

## 04.2 OPTIMISING THE DISTRIBUTION OF MRF

*Polycentric-dispersed model with 9 MRFs*

- 1. Polycentric-dispersed spatial structure is more cost efficient.*
- 2. Each urban subcentre needs around 3 facilities to cover the whole territory in a most eco-friendly and economical way.*
- 3. Facilities should be located about 12~15km away from the subcentre.*

THE END. THANKS
