Abstract

The assessment of potential evaporation or reference combined evaporation and transpiration is among the most important components for many hydro-climatic projects, for example, irrigational networks' design and management, water-cycle balance assessment studies, and assessment of aridity classification indices. Aridity classification indices such as UNEP, Thornthwaite and others are usually employed at large scale applications and require respective estimations of potential or reference combined evaporation and transpiration. The major problem in such applications is not only the limited availability of stations per se but also the limitation of many stations to provide data for a complete set of parameters such as rainfall (P), temperature (T), solar radiation (R_s), wind speed (u) and relative humidity (H_R). A complete set of climate parameters is prerequisite for accurate estimations of potential or reference combined evaporation and transpiration using the most advanced methods, which are expressions of energy balance (e.g., ASCE-standardized method, successor method of Penman-Monteith FAO-56). Unfortunately, large scale applications of aridity indices suffer from this limitation and the common solution is to use temperature-based formulas. The most popular and historical temperature-based formula is the one of Thornthwaite, which was developed to support the respective aridity classification index. The popularity of this formula is highly connected to a minimum requirement of average temperature per month and latitude at the location of interest. Considering the above, this study aims to develop a global database of local correction factors for the original Thornthwaite formula that will better support all hydro-climatic applications but mostly to support large scale applications of aridity indices, which are highly prone to data limitations. The hypothesis that is tested in this work is that a local correction factor that integrates the local mean effect of aforementioned climate parameters (R_s , H_R , u) can improve the performance of the original Thornthwaite formula and to convert it at the same time to a formula of reference combined evaporation and transpiration for short reference crop. The global database of local correction factors was developed using gridded climate data of the period 1950-2000 with grid size ~ 1 km at the equator which corresponds to 30 arc-sec spatial resolution from freely available climate geodatabases. The correction factors were produced as partial weighted averages of monthly ratios between the benchmark ASCE-standardized method for short reference crop versus the original formula of Thornthwaite by giving more weight to the warmer months and by excluding colder months of $E_{pr} < 45$ mm month⁻¹ where monthly ratios are highly unstable with unrealistic values. The validation of the correction factors was made using raw data from 525 stations of Europe, California-USA and Australia that cover periods mostly after 2000 and up to 2020. The validation procedure showed significant improvement in the estimations of reference combined evaporation and transpiration using the corrected Thornthwaite formula that led to a 19.4% reduction of RMSE for monthly and a 55% reduction of RMSE for annual estimations compared to the original formula. The variation of the correction factor was also investigated in different major Köppen climate classes and it was found that tends to increase in drier and warmer territories. The five major Köppen groups were ordered as follows $B > C > A > D > E$ considering the magnitude of the correction factors values. The corrected and original Thornthwaite formulas were also evaluated by their use in UNEP and Thornthwaite aridity indices using as a benchmark the respective indices estimated by the ASCE-standardized method. The analysis was made using the validation data of the stations and the results showed that the corrected Thornthwaite formula increased by 18.3% the accuracy of detecting identical aridity classes with ASCE-standardized method for the case of UNEP classification, and by 10.4% for the case of Thornthwaite classification in comparison to the original formula. The performance of the corrected formula was extremely improved especially in the case of non-humid classes of both aridity indices. The overall results revealed that the correction factors derived in this study can improve the performance of the original Thornthwaite formula providing better estimations of the aridity classification indices.

Acknowledgements

For the accomplishment of my additional thesis, I would like to thank my supervisors Dr ir. Coenders and Dr ir. ten Veldhuis and my advisor Dr Aschonitis who made it possible and supported my work through their valuable guidance. My research was upgraded and my thinking was actively triggered by your suggestions and your advice.

Introduction

The current discussion about climate change focuses often on how much the temperature will rise over the coming century. However, climate change cannot be described only by temperature since also precipitation and other climate parameters (e.g., humidity, radiation, wind speed) all together affect the climate. Additionally, their changes should not be analyzed separately, because together they affect the evaporation, and many theoretical climatic fields (e.g., climate classification methods, aridity indices etc.) in order to detect any possible changes. One of the basic problems in climate analysis methods is that they are based on evaporation, which is a complex process that is regulated by many factors such as temperature, relative humidity, solar radiation and wind speed. In most cases, climate databases or individual stations cannot provide a complete set of these parameters but what they can provide is at least temperature and precipitation. Evaporation is a process where the liquid water is changing state, using specific energy and becomes water vapour (vaporization). Three types of evaporation will be discussed to determine the differences: actual, potential and reference evaporation. The actual evaporation is the summary of all direct evaporation processes (open water evaporation, soil evaporation, interception evaporation and snow or ice evaporation), it is an important term of the water balance equation and is constrained by the water availability. Actual evaporation is difficult to be measured, so instead, the potential evaporation is calculated, because it can be calculated without the constrain of water availability. The relationship between actual and potential evaporation is that the actual is a proportion of the potential and the potential is setting the upper limit of the possible evaporation (Luxemburg & Coenders A., 2017). For the first time, the term combined evaporation and transpiration was introduced in the early 80s to incorporate the properties of an ideal grass crop in specific conditions and it is calculated using the potential evaporation multiplied with the crop factor of each specific crop (Brouwer & Heibloem, 1986; Irmak, 2008). Hereinafter, the reference combined evaporation and transpiration will be referred to as reference evaporation (E_r), for the sake of convenience. Many research studies have been done to derive empirical equations for the reference evaporation with reduced climate parameters; some of them are considered temperature-based, some of them are radiation-based and others are mass-transfer based.

Table 1.1: Different models for the calculation of the reference evaporation.

Model	Formula	Climate data
Alexandris et al. (2006)	$E_r = 0.057 + 0.227 \cdot C_2 + 0.634 \cdot C_1 + 0.0124 \cdot C_1 \cdot C_2$ <p>where: $C_1 = 0.6416 - 0.00784 \cdot H_R + 0.372 \cdot R_S - 0.00264 \cdot R_S \cdot H_R$ $C_2 = -0.0033 + 0.00812 \cdot T_{mean} + 0.101 \cdot R_S + 0.00584 \cdot R_S \cdot T_{mean}$</p>	T_{mean}, R_S, H_R
Baier and Robertson (1965)	$E_r = 0.09 \cdot (1.67021 \cdot T_{max} + 1.68085 \cdot TD + (1.159575 \cdot R_a) - 57.3404)$	T_{max}, T_{min}

	$E_r = 16 \cdot \left(10 \cdot \frac{0.36 \cdot (3 \cdot TD)}{J} \right)^a \cdot \frac{N \cdot n}{365}$	
Camargo et al. (1999)	$J = \sum_{i=1}^{12} j_i$	T_{max}, T_{min}
	$j_i = \left(\frac{T_{mean, i}}{5} \right)^{1.514}$	
	$\alpha = (6.75 \cdot 10^{-7}) \cdot J^3 - (7.71 \cdot 10^{-5}) \cdot J^2 + (1.79 \cdot 10^{-2}) \cdot J + 0.492$	
Droogers and Allen (2002)	$E_r = 0.00102 \cdot (T_{mean} + 16.8) \cdot R_a \cdot (TD)^{0.5}$	$T_{mean}, T_{max}, T_{min}$
Droogers and Allen (2002)	$E_r = 0.000530 \cdot (T_{mean} + 17.0) \cdot (TD - 0.0123 \cdot P)^{0.76}$	$T_{mean}, T_{max}, T_{min}, P$
Hargreaves and Samani (1982, 1985)	$E_r = c \cdot 0.408 \cdot (T_{mean} + 17.8) \cdot R_a \cdot (TD)^{0.5}$	$T_{mean}, T_{max}, T_{min}$
Aschonitis et al. (2017)	where: $c = 0.0023$ (original value) $c = c_{HS}$ (local coefficient from global grid)	
Hammon (1961)	$E_r = 13.97 \cdot \left(\frac{n}{12} \right)^2 \cdot \frac{e^o(T_{mean})}{1000}$	T_{mean}
Hammon (1963)	$E_r = 0.1651 \cdot \frac{n}{12} \cdot \frac{21.67 \cdot e^o(T_{mean})}{T_{mean} + 273.3}$	T_{mean}
Makkink (1957)	$E_r = 0.61 \cdot \frac{\Delta}{\Delta + \gamma} \cdot \frac{R_s}{\lambda} - 0.12$	T_{mean}, R_s
Malmström (1969)	$E_r = 0.409 \cdot e^o(T_{mean})$	T_{mean}
McCloud (1955)	$E_r = 0.254 \cdot 1.07^{1.8 \cdot T_{mean}}$	T_{mean}
Papadakis (1962)	$E_r = 0.5625 \cdot (e^o(T_{max}) - e^o(T_{min} - 2))$	T_{min}, T_{max}
Allen et al. (2005)	$E_r = \frac{0.408 \cdot \Delta \cdot (R_n - G) + \frac{\gamma \cdot u_2 \cdot (e_s - e_a) \cdot C_n}{(T_{mean} + 273.16)}}{\Delta + \gamma \cdot (1 + C_d \cdot u_2)}$	T_{mean}, R_s, H_R, u_2
Priestley and Taylor (1972), Aschonitis et al. (2017)	$E_r = a \cdot \frac{0.408 \cdot \Delta}{\Delta + \gamma} \cdot (R_n - G)$ where: $a = 1.36$ (original value) $a = \alpha_{PT}$ (local coefficient from global grid)	$T_{mean}, T_{max}, T_{min}, R_s$
Oudin et al. (2005)	$E_r = 0.408 \cdot R_a \cdot 0.01 \cdot (T_{mean} + 5) \text{ if } T_{mean} > 5^\circ\text{C}$ $E_r = 0 \text{ if } T_{mean} \leq 5^\circ\text{C}$	T_{mean}
Oudin et al. (2005)	$E_r = \left(\frac{n}{12} \right)^2 \cdot \exp\left(\frac{T_{mean}}{16} \right)$	T_{mean}
Thorntwaite (1948)	$E_p = 16 \cdot \left(\frac{10 \cdot T_{mean}}{J} \right)^a \cdot \frac{N \cdot n}{365}$ $J = \sum_{i=1}^{12} j_i,$ $j_i = \left(\frac{T_{mean, i}}{5} \right)^{1.514}$ $\alpha = (6.75 \cdot 10^{-7}) \cdot J^3 - (7.71 \cdot 10^{-5}) \cdot J^2 + (1.79 \cdot 10^{-2}) \cdot J + 0.492$	T_{mean}
Turc (1961)	$E_r = 0.013 \cdot \left(\frac{T_{mean}}{T_{mean} + 15} \right) \cdot \frac{23.88 \cdot R_s + 50}{\lambda} \text{ for } H_R \geq 50\%$ $E_r = \left(1 + \frac{50 - H_R}{70} \right) \cdot 0.013 \cdot \left(\frac{T_{mean}}{T_{mean} + 15} \right) \cdot \frac{23.88 \cdot R_s + 50}{\lambda} \text{ for } H_R < 50\%$	T_{mean}, R_s, H_R
WMO (1966)	$E_r = 0.1 \cdot (1.298 + 0.00934 \cdot u_2) \cdot (e_s - e_a)$	$T_{min}, T_{max}, H_R, u_2$
Valiantzas (2013, 2014)	$E_r = 0.0393 \cdot R_s \cdot \sqrt{T_{mean} + 9.5} - 0.19 \cdot R_s^{0.6} \cdot \varphi^{0.15} + 0.0061 \cdot (T_{mean} + 20) \cdot (1.12 \cdot T_{mean} - T_{min} - 2)^{0.7}$	T_{mean}, T_{min}, R_s

$$\begin{aligned}
 & \text{Valiantzas (2013, 2014)} \quad E_r = 0.0393 \cdot R_s \cdot \sqrt{T_{mean} + 9.5} - 0.19 \cdot R_s^{0.6} \cdot \varphi^{0.15} + 0.078 \\
 & \quad \quad \quad \cdot (T_{mean} + 20) \cdot \left(1 - \frac{H_R}{100}\right) \quad T_{mean}, R_s, H_R \\
 & \text{Valiantzas (2013)} \quad E_r = 0.0393 \cdot R_s \cdot \sqrt{T_{mean} + 9.5} - 2.4 \cdot \left(\frac{R_s}{R_a}\right)^2 + Cu \cdot (T_{mean} + 20) \\
 & \quad \quad \quad \cdot \left(1 - \frac{H_R}{100}\right) \quad T_{mean}, R_s, H_R
 \end{aligned}$$

where: $Cu = 0.054$ for $H_R > 65\%$ and $Cu = 0.083$ for $H_R \leq 65\%$

E_r : is the reference crop evaporation (mm d^{-1}), T_{mean} , T_{max} , T_{min} : Mean, maximum and minimum temperature ($^{\circ}\text{C}$), TD : difference between maximum and minimum temperature ($^{\circ}\text{C}$), R_s : incident solar radiation ($\text{MJ m}^{-2} \text{d}^{-1}$), R_n : the net radiation at the crop surface ($\text{MJ m}^{-2} \text{d}^{-1}$), u_2 : the wind speed at 2 m height above the soil surface (m s^{-1}), R_a : extraterrestrial solar radiation ($\text{MJ m}^{-2} \text{d}^{-1}$), H_R : relative humidity (%), Δ : slope of the saturation vapor pressure-temperature curve ($\text{kPa } ^{\circ}\text{C}^{-1}$), γ : psychrometric constant ($\text{kPa } ^{\circ}\text{C}^{-1}$), G : the soil heat flux density at the soil surface ($\text{MJ m}^{-2} \text{d}^{-1}$), e_s : the saturation vapor pressure (kPa), e_a : the actual vapor pressure (kPa), $e^{\circ}(T)$: saturation vapor pressure at air temperature T (kPa), φ : absolute value of latitude (rads), P : precipitation (mm month^{-1}), n : number of days in the month, N : mean length of daylight of the days of the month (hours), J : annual heat index, j_i : monthly heat index, α : the function of the annual heat index, λ is the latent heat of vaporization in MJ kg^{-1} ($\lambda = 2.45 \text{ MJ kg}^{-1}$ at a temperature of $20 \text{ } ^{\circ}\text{C}$). C_n and C_d : are constants, which vary according to the time step and the reference crop type and describe the bulk surface resistance and aerodynamic roughness. Eq.4 can be applied for two types of reference crop, this study focuses on the short reference crop (ASCE-short), which corresponds to clipped grass of 12 cm height and surface resistance of 70 s m^{-1} where the constants C_n and C_d have the values 900 and 0.34, respectively (Allen et al., 2005).

For the estimation of evaporation, there are many empirical equations (Table 1.1). The selection of the appropriate method, considering also climate data availability, has received considerable attention and has triggered remarkable debate (Trenberth, et al., 2014; Tegos, Malamos, & Koutsoyiannis, 2015; Rezaei, Valipour, & Valipour, 2016; Zhang, et al., 2016; Valipour, Gholami Sefidkouhi, & Raeini-Sarjaz, 2017; Feng, Trnka, Hayes, & Zhang, 2017). One of the most widely used potential evaporation models that were developed in the previous century is Thornthwaite's formula (Thornthwaite, 1948). This specific model requires only mean monthly temperature data and is a viable solution for a climatologist/hydrologist in case of reduced data. Estimations of global trends under climate change cause an argument due to the differences between the Penman-Monteith concept and Thornthwaite concept of reference evaporation assessments (Sheffield, Wood, & Roderick, 2012; Van Der Schrier, Barichivich, Briffa, & Jones, 2013; Trenberth, et al., 2014; Yuan & Quiring, 2014).

The Thornthwaite method is a simple and empirical scheme for calculating potential evaporation using only air temperature data and the maximum amount of sunshine duration as of function of latitude. In the Thornthwaite formula (Thornthwaite, 1948) the monthly mean temperature was correlated with evaporation using an exponential relationship, as determined from the water balance, for valleys in the central and eastern USA, where there was a supply of surface water. A modification of Thornthwaite's original approach was also presented by Willmott et al. (1985) by introducing a parameterization for a range of monthly mean temperature varying below zero and above 26.5 degrees Celsius. The Thornthwaite method overestimates the evaporation in humid climates and underestimates it in arid climates (Pereira & Pruitt, 2004; Castañeda & Rao, 2005; Trajkovic & Kolakovic, Evaluation of reference evapotranspiration equations under humid conditions, 2009a), and thus, many efforts have been made to amend the parameters or constants of the empirical formula to adapt it to various geographical zones (Jain & Sinai, 1985; Pereira & Pruitt, 2004; Castañeda & Rao, 2005; Zhang, Liu, Wei, Liu, & Zhang, 2008; Bakundukize, van Camp, & Walraevens, 2011; Yang, Ma, Zheng, & Duan, 2017). Jain and Sinai (1985) modified the constant in the general equation of

the Thornthwaite formula based on the min-max range of the annual mean air temperature in order to calculate the evaporation for semi-arid conditions. [Pereira and Pruitt \(2004\)](#) proposed an adaptation of the Thornthwaite scheme to estimate the daily evaporation in two contrasting environments in the USA and Brazil. [Castaneda and Rao \(2005\)](#) recalibrated the coefficient of the main equation of the Thornthwaite method based on estimations of reference evaporation using the FAO Penman-Monteith method in southern California. [Zhang et al. \(2008\)](#) used a modified formula to estimate the actual evaporation in cropland, shrubland and forest located in the subalpine region of southwestern China. [Bakundukize et al. \(2011\)](#) used two modifications and the original Thornthwaite method to groundwater recharge estimations in the inter-lacustrine zone of East Africa. [Yang et al. \(2017\)](#) presented a method to quantitatively identify the differences in the spatiotemporal variabilities of global drylands between the Thornthwaite and Penman-Monteith parameterizations for E_r .

The climate of an area is playing a key role in the aforementioned spatiotemporal variabilities. The first try to classify the climate of a specific area has been done by Köppen at the early of the 20th century and the middle of the same century, Geiger updated that classification. The aforementioned classification uses precipitation and temperature and contains 30 classes (3 tropical classes (A), 4 arid (B), 9 temperate (C), 12 cold (D) and 2 polar (E)); each class is coded with a three-digit system, the first element is representing the groups of vegetation, the second is representing the rainfall of the area and the last one (where is present), stands for the air temperature ([Kottek, Grieser, Beck, Rudolf, & Rubel, World map of the Köppen-Geiger climate classification updated, 2006](#)).

The climate change in terms of global warming is having an important impact on arid areas ([Kimura, 2020](#)) which are covering about the 40% of the continental Earth ([Ashraf, Yazdani, Mousavi-Baygi, & Bannayan, 2014](#)). The increasing carbon dioxide emissions are going to cause an increment of temperature that will result in water scarcity and drought in arid areas ([Kimura, 2020](#)). The role of aridity indices is very important to apply an integrated climate analysis of a region; many popular climate/aridity indices such as those of [UNEP \(1997\)](#), [Thornthwaite \(1948\)](#), [Holdridge \(1967\)](#) etc are based on formulas that require data of precipitation (P) and evaporation (E). In large scale applications of climate/aridity indices at country/continent/global scale, there is always the problem of data limitation for estimating evaporation E using methods that require complete data of climate parameters (i.e., temperature, solar radiation, relative humidity, wind speed). A solution to this problem is the use of temperature-based formulas of E ([Alexandris, Kerkides, & Liakatas, 2006](#); [Baier & Robertson, 1965](#); [Camargo et al., 1999](#); [Droogers & Allen, 2002](#); [Hargreaves & Samani, 1982](#); [Aschonitis, et al., 2017a,b](#); [Hamon W. R., 1963](#); [Hamon W. R., 1963](#); [Makkink, 1957](#); [Malmström, 2007](#); [Turc, 1961](#), [WMO, 1966](#); [Thornthwaite, 1948](#); [Allen et al. 2002](#)).

To sum up, the necessity of evaporation calculation lays to the fact that is a key variable of the water-cycle; the ASCE standardized Penman-Monteith method, which estimates the reference evaporation accurately, is taking four inputs, some of them are not easily measured (R_s , u , H_R). On the other hand, Thornthwaite's empirical formula is only using the average temperature and the latitude value for the calculation of the potential evaporation; accurate measurements of temperature are easy to be done or obtained from open source databases for the whole of the world. Considering the above, this study aims to develop a global database of local correction factors for the original Thornthwaite formula that will better support all hydro-climatic applications (irrigation design and management, water balance assessment studies, and even climate change assessment ([Muhammad et al. 2019](#); [Trajkovic 2007](#)) but mostly to support large scale applications of aridity indices, which are highly prone to data limitations. The hypothesis that is tested in this work is that a local correction factor that integrates the local mean effect of wind speed, humidity and solar radiation can improve the performance of the original Thornthwaite formula and to convert it at the same time to a formula of reference evaporation for short reference crop.

2

Materials and Methods

2.1. Method

2.1.1. Derivation/calibration of Thornthwaite correction factor

As it has been mentioned before, the calculation of reference evaporation with Penman-Monteith is often difficult due to lack of data that is needed; on the other hand, the empirical Thornthwaite formula is used for the calculation of the potential evaporation only using temperature and latitude. The original Thornthwaite model was calibrated with stations located in the east-central United States in humid climate conditions (Thornthwaite, 1948); though, many studies have shown that its application can be extended globally, over mid-latitude climate (Sepaskhah & Razzaghi, 2009). The following methodology will be applied to express the Penman-Monteith reference evaporation as a function of the Thornthwaite using a correction factor. The monthly potential evaporation using the Thornthwaite (1948) method is estimated as follows:

$$E_p = 16 \cdot \left(\frac{10 \cdot T_{mean}}{J} \right)^{\alpha} \cdot \frac{N \cdot n}{365} \quad (1)$$

$$J = \sum_{i=1}^{12} j_i,$$

$$j_i = \left(\frac{T_{mean,i}}{5} \right)^{1.514} \quad (2a,b,c)$$

$$\alpha = (6.75 \cdot 10^{-7}) \cdot J^3 - (7.71 \cdot 10^{-5}) \cdot J^2 + (1.79 \cdot 10^{-2}) \cdot J + 0.492$$

$$N = \frac{24}{\pi} \cdot \omega_s$$

$$\omega_s = \frac{\pi}{2} - \arctan \left[\frac{-\tan(\varphi) \cdot \tan(\delta)}{X^{0.5}} \right] \quad (3a,b,c)$$

$$\text{where: if } X \leq 0: X = 0.00001 \text{ else } X = 1 - [\tan(\varphi)]^2 \cdot [\tan(\delta)]^2$$

$$\delta = 0.409 \cdot \sin \left(2 \cdot \pi \cdot \frac{d_j}{365} - 1.39 \right)$$

where E_p : mean monthly potential evaporation of month i (mm month⁻¹), $T_{mean,i}$: mean monthly temperature (°C), n : number of days in the month, N : mean length of daylight of the days of the month (hours), J : annual heat index, j_i : monthly heat index, α : expression of annual heat index and d_j : Julian day.

The benchmark method that was used for developing correction factors for the temperature-based method of Thornthwaite is ASCE standardized method (former FAO-56), which estimates reference evaporation from short clipped grass, and it is estimated using the ASCE standardized method as it was proposed by Allen (2005):

$$E_r = \frac{0.408 \cdot \Delta \cdot (R_n - G) + \frac{\gamma \cdot u_2 \cdot (e_s - e_a) \cdot C_n}{(T_{\text{mean}} + 273.16)}}{\Delta + \gamma \cdot (1 + C_d \cdot u_2)} \quad (4)$$

where E_r : is the reference crop evaporation or reference evaporation (mm d^{-1}), Δ : is the slope of the saturation vapour pressure-temperature curve ($\text{kPa } ^\circ\text{C}^{-1}$), R_n : is the net radiation at the crop surface ($\text{MJ m}^{-2} \text{d}^{-1}$), G : is the soil heat flux density at the soil surface ($\text{MJ m}^{-2} \text{d}^{-1}$), γ : is the psychrometric constant ($\text{kPa } ^\circ\text{C}^{-1}$), u_2 : is the wind speed at 2 m height above the soil surface (m s^{-1}), e_s : is the saturation vapour pressure (kPa), e_a : is the actual vapour pressure (kPa), T_{mean} : is the mean daily air temperature ($^\circ\text{C}$), C_n and C_d : are constants, which vary according to the time step and the reference crop type and describe the bulk surface resistance and aerodynamic roughness. Eq.4 can be applied for two types of reference crop, this study focuses on the short reference crop (ASCE-short), which corresponds to clipped grass of 12 cm height and surface resistance of 70 s m^{-1} where the constants C_n and C_d have the values 900 and 0.34, respectively (Allen et al., 2005).

The derivation of a correction factor for Eq.1 using as a benchmark the monthly values of Eq.4 (same to FAO-56) is performed based on the same procedure proposed by Aschonitis et al. (2017) that has been used before for developing partial weighted annual correction factors for Priestley-Taylor and Hargreaves-Samani methods. The procedure starts with the derivation of the monthly correction coefficient $c_{th,i}$ for each month i directly by dividing Eq.4 by Eq.1 of each month. Applying this procedure, twelve values of monthly $c_{th,i}$ are produced. The 12 monthly $c_{th,i}$ coefficients are then used to build mean annual coefficients. As it was mentioned in Aschonitis et al. (2017), the efficiency of mean annual correction factors is mainly associated with the fact that they are corresponding better for larger evaporation levels (i.e., the values of E_r during summer/hot months) and not the smaller values where the absolute errors ($e_i = E_{ri} - E_{pi}$) are smaller. In that scope, the use of weighted annual averages based on the monthly $c_{th,i}$ coefficients are estimated considering the participation weight of each month in the annual E_r ; the weight of each month was calculated by dividing the reference evaporation of each month into the annual reference evaporation.

Under cold conditions, reference evaporation is very low and sensitive to climate parameters (e.g., wind speed) a fact which means that the aforementioned division can lead to unrealistic monthly coefficients $c_{th,i}$ that may cause a negative impact on the averaged coefficients and led to nonrealistic coefficients (one order of magnitude deviation from 1). The solution of that situation came by setting a low limit of E_p and E_r before the inclusion of their $c_{th,i}$ in the weighted average estimations. In order to set this limit, a preliminary analysis was done by a trial-and-error method, this methodology led to the rejection of values lower than 1.5 millimeter per day which is equal to 45 millimeters for the whole month.

The derivation of the partial weighted average is based on monthly $c_{th,i}$ values after excluding the $c_{th,i}$ values of those months with E_r and/or $E_p \leq 45 \text{ mm month}^{-1}$:

$$c_{th,i} = \frac{E_{ri}}{E_{pi}} \quad (5)$$

$$\text{If } E_{ri} > 45 \text{ mm month}^{-1} \text{ then } F_{ri} = 1 \text{ else } = 0 \quad (6)$$

$$\text{If } E_{pi} > 45 \text{ mm month}^{-1} \text{ then } F_{mi} = 1 \text{ else } = 0 \quad (7)$$

$$E_{ri}^{adj} = E_{ri} \cdot F_{ri} \cdot F_{mi} \quad (8)$$

$$AE_r^{adj} = \sum_{i=1}^{12} (E_{ri}^{adj}) \quad (9)$$

$$C_{th} = \sum_{i=1}^{12} \left(\frac{E_{ri}^{adj}}{AE_r^{adj}} \cdot c_{th,i} \right) \quad (10)$$

where $c_{th,i}$: is the monthly correction coefficient, F_{ri} and F_{mi} : are corresponding to Eq.1 and Eq.4 and are having a binary form in order to apply a filtering on the evaporation values, E_{ri}^{adj} : is the adjusted monthly value of E_{ri} from Eq.4, AE_r^{adj} : is the sum of the monthly E_{ri}^{adj} adjusted values, C_{th} : annual partial weighted average of the monthly $c_{th,i}$ coefficients and i : is each month's index

Considering the above, the final corrected Thornthwaite formula for monthly calculations is given by the following equation:

$$E_{psi} = C_{th} \cdot E_{pi} \quad (11)$$

where E_{psi} : is the corrected temperature-based short crop evaporation (mm month⁻¹) of each month i .

The above led to the adjustment of the annual C_{th} (Eq.10) for every location during the period 1950-2000 on the globe based on mean monthly E_r and E_p taking:

- the gridded mean monthly data for the temperature Hijmans et al. (2005) that were further used to estimate the mean monthly gridded original Thornthwaite E_p (Eq.1) for the period 1950-2000 (in the form of 12 raster datasets of E_p for each month),
- the respective mean monthly grids of E_r based on ASCE-standardized method (Eq.1) (Aschonitis et al. (2017)) (in the form of 12 raster datasets of E_r for each month).

2.1.2. Variation of Thornthwaite correction factor in major climate groups of Köppen-Geiger climate classification

Aiming to investigate variations of the final values in the global map of the C_{th} factor concerning climate, the major groups of Köppen-Geiger climate classification were used. A total number of 114,065 randomly generated sampling points, with the density of 1000 stations per million km², was used to extract the C_{th} factor and the 12 mean monthly values of T and P from Hijmans et al. (2005) project. Using the monthly average precipitation and temperature, the Köppen-Geiger climate classification was assessed for each sampling position based on the criteria of Table 2.1 obtained from Peel et al. (2007). The C_{th} values were divided into A, B, C, D, E groups of Köppen-Geiger, and their distribution within each group was analysed using a faction to investigate the distribution of the correction factor. Due to Bernardo (2005), the implementation of the module *p.interval* which is part of the *LaplacesDemon* in R statistic language, is able also to reveal the modality of the distribution and apply specific confidence level for the sample (e.g., 2.5 to 97.5 %). The aforementioned climate classification was followed as it was described from the paper of Peel et. al 2007.

2.1.3. Validation of C_{th} based on stations data

The validation procedure with the data of the 525 stations was performed by comparing the mean monthly and the mean annual values of E_r of ASCE (Eq.4) versus the original E_p (Eq.1) and versus the modified E_{ps} Thornthwaite formula (Eq.11) for short reference crop taking into account the annual partial weighted average coefficients C_{th} . The validation was made separately for each database of stations (ECAD, AGBM, CIMIS) but also all together using the following five statistical criteria were applied to the results to assess their accuracy.

$$MAE = \frac{1}{N} \sum_{i=1}^N |S_i - O_i| \quad (12)$$

$$ME = \frac{1}{N} \sum_{i=1}^N (S_i - O_i) \quad (13)$$

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^N (S_i - O_i)^2} \quad (14)$$

$$R_{Sqr} = \left[\frac{\sum_{i=1}^N (O_i - \bar{O}_i)(S_i - \bar{S}_i)}{\sqrt{\sum_{i=1}^N (O_i - \bar{O}_i)^2 \sum_{i=1}^N (S_i - \bar{S}_i)^2}} \right]^2 \quad (15)$$

$$d = 1 - \frac{\sum_{i=1}^N (S_i - O_i)^2}{\sum_{i=1}^N (|S_i - \bar{O}_i| + |O_i - \bar{O}_i|)^2} \quad (16)$$

where *MAE*: is the mean absolute error (mm month⁻¹), *ME*: is the mean error (mm month⁻¹), *RMSE*: is the root mean square error (mm month⁻¹), *R_{Sqr}*: is the coefficient of determination (-) and *d*: is the index of agreement (-), *O*: is the observed value (i.e., *E_r*) (mm month⁻¹), *S*: is the simulated value from the model (i.e., *E_p* or *E_{ps}*) (mm month⁻¹), *N*: is the number of observations, *i*: is the subscript referred to each observation.

Table 2.1: Description and characteristics of statistical criteria

Statistical criterion	Abbreviation	Range	Value of perfect fit
Mean Absolute Error	<i>MAE</i>	0 and +∞	0
Mean Error	<i>ME</i>	-∞ and +∞	0
Root Mean Squared Error	<i>RMSE</i>	0 and +∞	0
<i>R_{Sqr}</i> statistic (Coefficient of Determination)	<i>R_{Sqr}</i>	0 and 1	1
Index of Agreement	<i>d</i>	-∞ and 1	1

2.1.4. Evaluation of *C_{th}* use in aridity and aridity/humidity indices based on stations data

The role of the new corrected version of Thornthwaite (Eq.11) as an internal parameter of aridity indices was also evaluated against the original method (Eq.1). For this purpose, the *A_{IUNEP}* (UNEP, 1997) and *A_{ITH}* (Thornthwaite, 1948) climate/aridity indices were used. The two indices estimated based on the *E_r* of ASCE (Eq.4) were used as a benchmark in order to compare the respective indices calculated with the original Thornthwaite (Eq.1) and the corrected one (Eq.11) for the stations' data. The comparative analysis was performed using the same metrics of Eqs.12-16 and through % similarity comparisons in the derivation of aridity code classes. The *A_{IUNEP}* is the simplest method for hydroclimatic analysis and it is given by the following equation:

$$A_{IUNEP} = \frac{P_y}{E_y} \quad (17)$$

where *P_y*: mean precipitation (mm y⁻¹) and *E_y*: mean annual potential evaporation (mm y⁻¹).

Applying the Eq.16, the characterization of the area is corresponding to five classes (UNEP, 1997; Cherlet, 2018):

- $0.05 > A_{IUNEP}$ → Hyper-arid
- $0.05 \leq A_{IUNEP} < 0.2$ → Arid
- $0.2 \leq A_{IUNEP} < 0.5$ → Semi-arid
- $0.5 \leq A_{IUNEP} < 0.65$ → Dry subhumid
- $0.65 \leq A_{IUNEP}$ → Humid

It is also popular to merge the classes > 0.65 to a humid one. The UNEP index does not consider the effect of seasonal variation of precipitation and potential evaporation. The A_{ITH} aridity – humidity index is calculated as follows:

$$S = \sum_{i=1}^{12} (P_i - E_i) \quad \text{and} \quad D = \sum_{i=1}^{12} (E_i - P_i) \quad (18a,b)$$

$$A_{ITH} = 100 \cdot \frac{S - 0.6D}{E_y} \quad (19)$$

where S (mm y^{-1}) is the positive difference between evaporation and precipitation ($P_i - E_i > 0$, (if negative $S = 0$), D (mm y^{-1}), is the positive difference between precipitation and evaporation ($P_i - E_i > 0$ (if negative $D = 0$).

The various climatic types according to A_{ITH} values are the following:

- $-60 > A_{ITH}$ → Hyper-arid
- $-60 \leq A_{ITH} < -40$ → Arid
- $-40 \leq A_{ITH} < -20$ → Semi-arid
- $-20 \leq A_{ITH} < 0$ → Dry sub-humid
- $0 \leq A_{ITH} < 20$ → Moist sub-humid
- $20 \leq A_{ITH} < 40$ → Humid
- $40 \leq A_{ITH} < 60$ → Humid
- $60 \leq A_{ITH} < 80$ → Humid
- $80 \leq A_{ITH} < 100$ → Humid
- $100 \leq A_{ITH}$ → Hyper-humid

2.2. Data

In this study, global gridded data from two databases were used. The first [Hijmans et al. \(2005\)](#) supplies open-source gridded data of average precipitation P and temperature T per month for the period 1950-2000 (WorldClim version 1.2) with a resolution of ~ 1 km grid resolution. The described data is presented in the [Fig. 2.2a, b](#). The second database is the one of [Aschonitis et al. \(2017\)](#), which provides gridded data of mean monthly reference evaporation E_r of the period 1950-2000 at 30 arc-sec ($\sim 1 \times 1$ km) spatial resolution ([Fig. 2.2c](#)). The method used for estimating E_r is the one of ASCE-standardized method (former FAO-56), which estimates reference evaporation from short clipped grass ([Allen et al., 2005](#)). The database of E_r was built using temperature from the first raster of [Hijmans et al. \(2005\)](#) and for this reason, the two gridded databases are compatible for being used and combined in the common analysis.

For the validation of the correction factors, it was necessary to compare its performance with in-situ data; the use of meteorological data obtained from ground stations was important. The network of California, USA (CIMIS) was the first option based on the geometry and the high density of the network. The advantage of the specific area in USA is its climate variability and the rich landscape. In total 60 stations ([Fig. 2.1a](#)) were used from CIMIS database that has at least 15 years of observations with a significant part of their observations after 2000 (some stations, that do not follow the first rule were selected due to their special climate Köppen class or the high altitude of their location). From the total stations, it has been excluded these that are located in extreme climates or/and high elevation.

The large variability that also presenting in the Australian continent (from tropical to desert) such as the well distributed and enough dense network, made it adequate to be included in the study. The second stations' network is the AGBM and consists of 80 stations ([Fig. 2.1b](#)), that have at least 15 years of observations with a significant part of their observations after 2000 (the same filtering that was done for the CIMIS has been done for AGBM also).

The third database is the ECAD database (European Climate Assessment & Database, <https://www.ecad.eu>). This database is a network that contains more than 20,000 stations throughout Europe and provides daily observations of climatological parameters. In this study, a final number of 385 stations (Fig. 2.1c) was selected because they contained complete data of precipitation, temperature, solar radiation, relative humidity and wind speed for a period of at least 20 years (with a significant part of their observations after 2000). The total number of stations used in the study from the three databases is 525 (Table S1).

3

Results

3.1. Derivation of the C_{th} correction factors and analysis of its variation in major Köppen-Geiger groups

The global map of the C_{th} correction factor was developed following the procedure described in Section 2.1 and it is given in Fig.3.1a. The C_{th} map is given together with the additional map of 114,065 randomly selected sampling points providing information about their Köppen-Geiger climate classification (Fig.3.1b), which was identified following the criteria of Table 2.1 using Hijmans et al. (2005) database. These points were used to evaluate the variation of C_{th} values inside the major groups as described in section 2.1.2. The HPD distributions of C_{th} values separately for each major climate group but also all groups together are given in Fig.3.2a-f, while their respective statistics are given in Table 3.1. Places with $C_{th} = 0$ due to extreme cold (T_{mean} always < 0) were not included in the sampling points. According to Table 3.1, the five major Köppen-Geiger groups are ordered as follows $B > C > A > D > E$ considering the magnitude of their mean, median, mode C_{th} values.

Considering C_{th} as an indirect metric of error, it is observed that there are regions in the globe mostly belonging to the B group where the original formula of Thornthwaite greatly underestimates reference evaporation (E_r can be more than double from E_p). On the other hand, there are regions mostly belonging to the D and E groups where the original formula of Thornthwaite greatly overestimates reference evaporation (E_p can be more than double from E_r). In general, E_p overestimates reference evaporation in environments of high humidity and low water vapour deficit, while it underestimates it in dry environments with high water vapour deficit. Finally, E_p is showing the most symmetric behaviour at a global scale considering the statistics of all Köppen-Geiger groups of Table 3.1. Finally, it is very interesting to investigate the behaviour of C_{th} through the regions that Thornthwaite originally used for the derivation of the Eq.1. Due to Willmott et al. (1985), Thornthwaite used lysimeters at the East part of the U.S., the value of C_{th} in the aforementioned areas is close to neutral (0.9 – 1.1).

3.2. Validation of the C_{th} correction factors

The validation of the derived C_{th} factors (Fig.3.1a) was performed for each of the three datasets of stations (California-CIMIS, Australia-AGBM, Europe-ECAD), separately, by comparing in 1:1 plots the performance of mean monthly values of original Thornthwaite E_p (Eq.1) and mean monthly E_{ps} (Eq.11) versus the benchmark values of E_r (Eq.4) (Fig.3.3a-f). The same comparisons were also performed using the mean annual values of the respective methods (Fig.3.4a-f). The statistical criteria (Eqs.12-16) for both monthly and annual comparisons for each one of the three datasets of stations are given in Table 3.2. The respective monthly and annual comparisons after merging all the stations from the three datasets are also presented in Fig.3.5a-d. From the results shown in Figs.3.3, 3.4, 3.5 and Table 3.2, it is observed that E_{ps} much better performance compared to the original Thornthwaite formula E_p in all cases providing not only better monthly but also better annual reference evaporation estimations that approximate the values of ASCE for short reference grass.

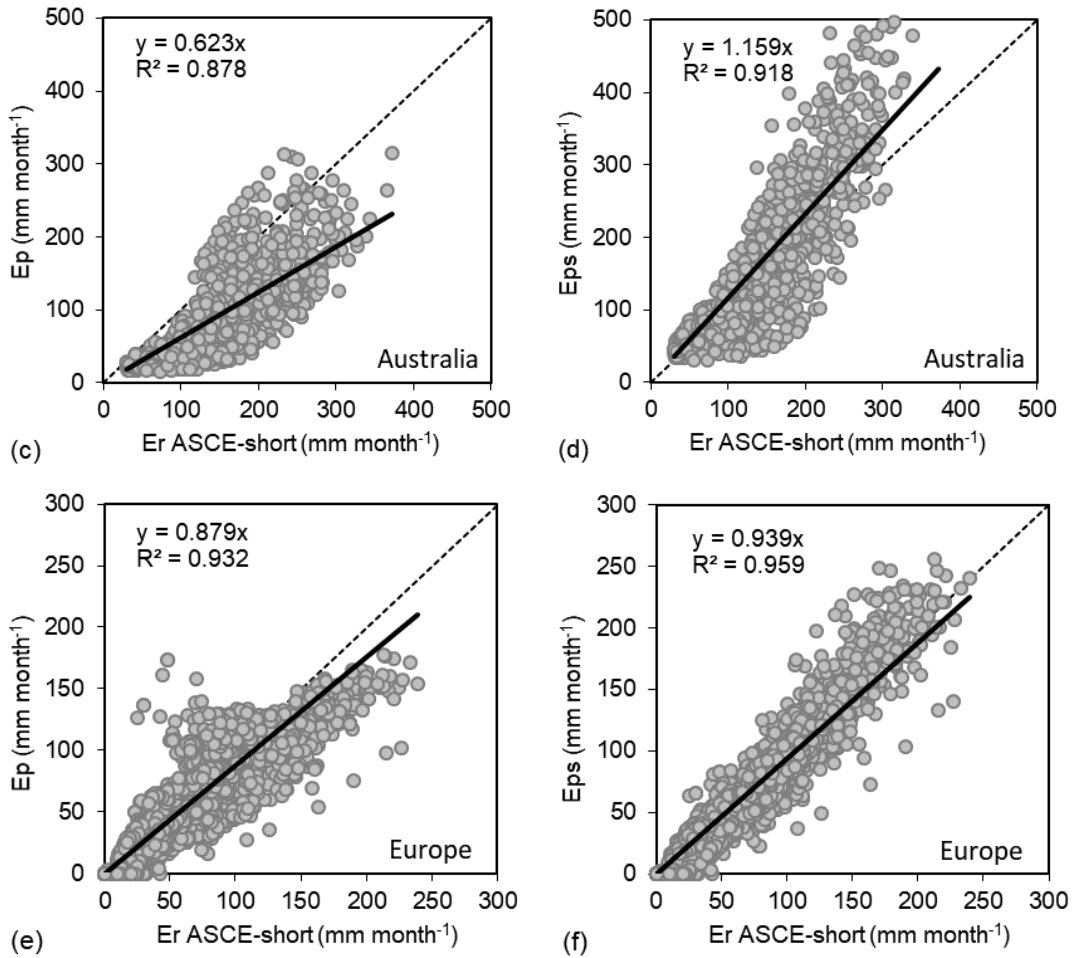

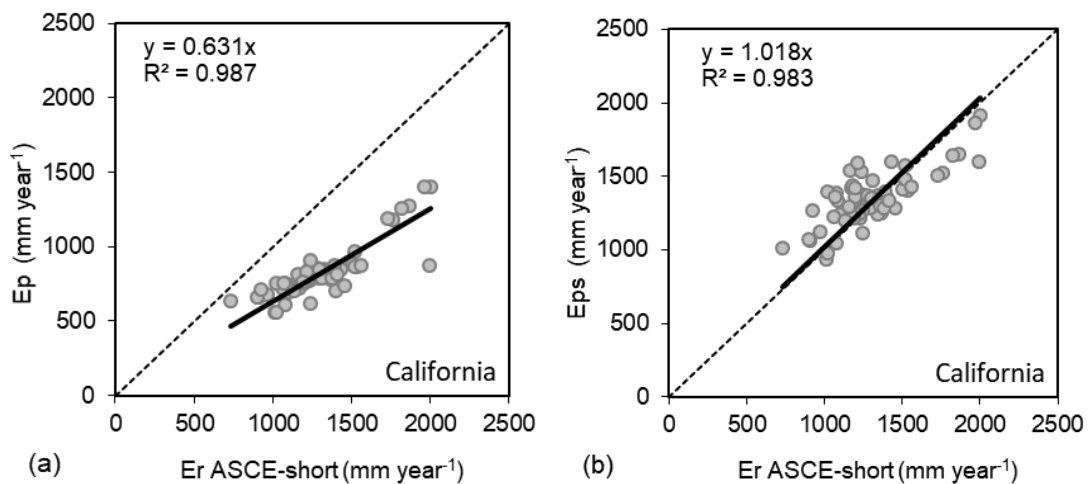

Figure 3.3: *Left side:* 1:1 plots of mean monthly E_p (Eq.1) versus mean monthly E_r (Eq.4) (a) for 60 CIMIS stations of California, (c) for 80 AGBM stations of Australia and (e) for 385 ECAD stations of Europe, and *Right side:* 1:1 plots of mean monthly E_{ps} (Eq.11) versus mean monthly E_r (Eq.4) (b) for 60 CIMIS stations of California, (d) for 80 AGBM stations of Australia and (f) for 385 ECAD stations of Europe.

3.3. Evaluating the use of C_{th} factor in aridity indices

The use of derived C_{th} factors (Fig.3.1a) in A_{IUNEP} and A_{ITH} aridity indices was evaluated considering all 525 stations (California-CIMIS, Australia-AGBM, Europe-ECAD) that were included in the validation procedure of the previous analysis. The evaluation was performed both by using statistical metrics (Eqs.12-16) for comparing the values of the indices or by converting their values to aridity classes in order to compare their correspondence. The statistical metrics of Eqs.12-16 for the evaluation between E_p vs. E_r and E_{ps} vs. E_r when they are applied in the A_{IUNEP} and A_{ITH} aridity indices considering only non-humid or humid classes based on the data of all 525 stations are given in Table 3.3.

For the case of A_{IUNEP} , the analysis was made by comparing the performance of the index when estimated using the original Thornthwaite E_p (Eq.1) and using the mean monthly E_{ps} (Eq.11) versus the A_{IUNEP} benchmark values estimated using E_r (Eq.4) in 1:1 log-log plots.

The results of the analysis are given in Figs. 3.6a,b for E_p and E_{ps} , respectively. The 1:1 plots were visualized with log-transformed axes in order to optimize the visualization of high A_{IUNEP} deviations based on E_p for A_{IUNEP} values < 0.65 , which is the minimum threshold value of the last Humid class of A_{IUNEP} classification. The visual comparison clearly shows that E_{ps} outperforms the E_p in the range of 0-0.65 where there are all the divisions of A_{IUNEP} classes (Table 3.3). Considering the full set of 5 classes of the A_{IUNEP} index and the complete set of stations, the A_{IUNEP} of E_{ps} provided 93% of identical codes with the A_{IUNEP} of E_r , while A_{IUNEP} of E_p provided 76% of identical codes. For the case of A_{ITH} , the analysis was made in the same way as A_{IUNEP} . In order to visualize the negative values of A_{ITH} in 1:1 log-log plots, a constant value was added (+70) to all the A_{ITH} values. The results of the analysis are given in Figs. 3.7a,b for E_p and E_{ps} , respectively. The 1:1 plots were again visualized with log-transformed axes in order to optimize the visualization of high A_{ITH} deviations based on E_p for A_{ITH} values < 20 , which is the minimum threshold value of the Humid B and A classes of A_{ITH} classification. The comparison again shows that E_{ps} outperforms the E_p in the A_{ITH} range of < 20 (Table 3.3). The A_{ITH} of E_{ps} provided 58% of identical codes, while the A_{ITH} of E_p provided 52% of identical codes with the A_{ITH} of E_r according to the 10 aridity-humidity classes of the index.

Table 3.3 verifies the better performance of E_{ps} compared to E_p in both A_{IUNEP} and A_{ITH} aridity indices for the non-humid classes. On the other hand, the statistics showed that E_p showed better performance in both A_{IUNEP} and A_{ITH} aridity indices for humid classes, but this result is of less importance and not so robust for the following reasons:

- In the case of $A_{IUNEP} > 0.65$, there is only one Humid class and thus there is no point to compare the performance of E_p and E_{ps} in A_{IUNEP} from a statistical point of view since their values will always lead to the same classification code/characterization (i.e. Humid).
- In the case of $A_{ITH} > 20$, the detailed division of five humid classes (B1, B2, B3, B4, A) provided by A_{ITH} was proposed for the alternative use of the index as “humidity index” (Thornthwaite, 1948). Merging the B and A classes to one Humid class, as in the case of A_{IUNEP} , the successful identical codes are raised to 76% for E_{ps} and 63% for E_p indicating in both cases (merging or no merging of humid A_{ITH} classes) the better performance of E_{ps} compared to E_p despite the worst statistical metrics.

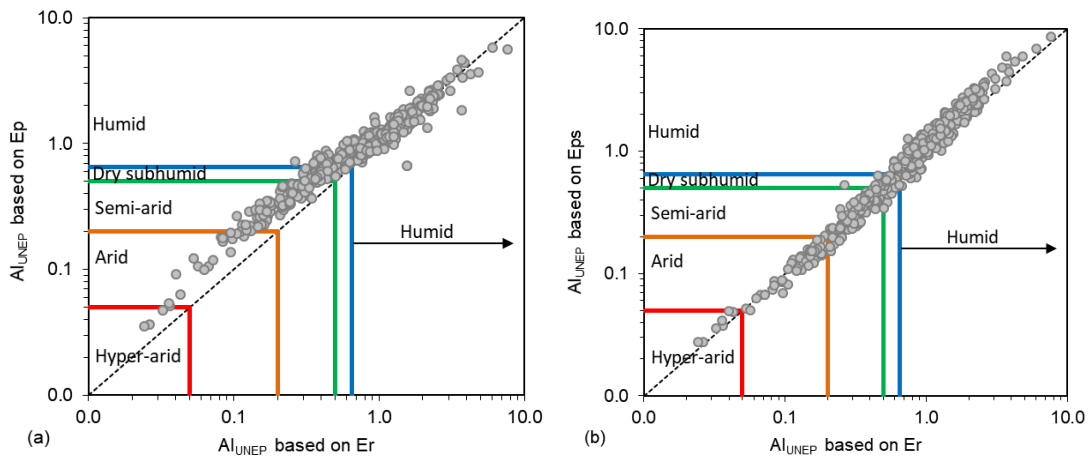

Figure 3.6: 1:1 log-log plots of (a) A_{IUNEP} using mean monthly E_p (Eq.1) versus A_{IUNEP} using mean monthly E_r (Eq.4), (b) A_{IUNEP} using mean monthly E_{ps} (Eq.11) versus mean monthly E_r (Eq.4) using the data of all 525 stations from the three databases of CIMIS, AGBM, ECAD.

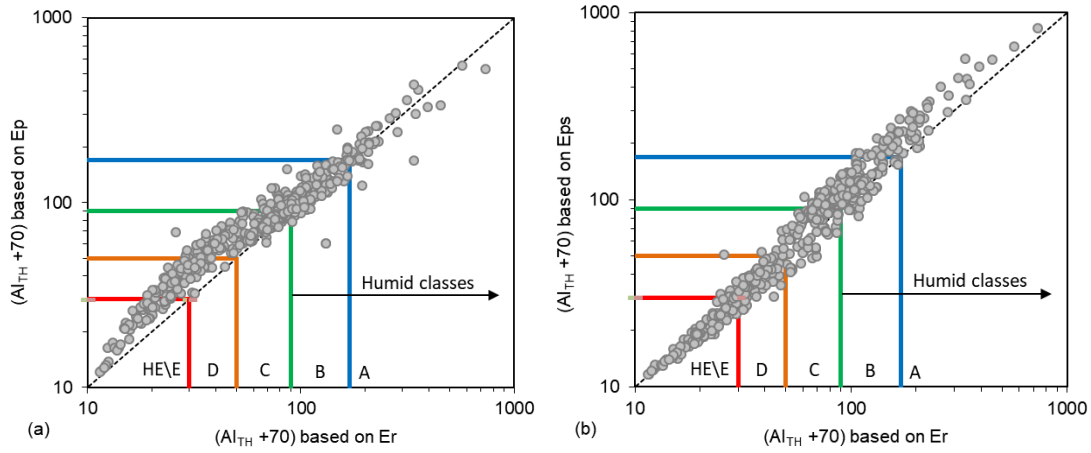

Figure 3.7: 1:1 log-log plots of (a) A_{ITH} using mean monthly E_p (Eq.1) versus A_{ITH} using mean monthly E_r (Eq.4), (b) A_{ITH} using mean monthly E_{ps} (Eq.11) versus mean monthly A_{ITH} (Eq.4) using the data of all 525 stations from the three databases of CIMIS, AGBM, ECAD.

Discussion

4.1. The validity of the derived C_{th} of 1950-2000 for periods after 2000

The calibration of local C_{th} factors at a global scale was performed using the mean monthly grid datasets for the period of 1950-2000 doing the assumption of relevant stable climate, on the other hand, the procedure of the validation was performed using stations data from California and Australia that are expanded up to 2016 and data from Europe that are expanded up to 2020 (Table S1). The reasons for choosing the grid datasets for calibration of C_{th} factors are the following:

- They are in the form of high-resolution grids, which have been developed using interpolation techniques that include the effects of latitude, longitude and elevation. These grids allow deriving more representative C_{th} values for every position even when weather stations do not locally exist.
- They cover a large period of time (i.e., 1950-2000) so they can provide more representative mean annual partial weighted average C_{th} values. The upper threshold of the year 2000 of these grids also allows the validation dataset of stations to be more valid since the larger part of their data is after 2000 and this reduces the possibility of having been used in grids' development.

On the other hand, several works have shown climate differences after 2000 (Hansen et al., 2010; McVicar et al., 2012a,b; Wild et al., 2013; Willet et al., 2014; Sun et al., 2017) a situation that is crucial for the performance and the validity of the correction factor C_{th} . The overall effect of all possible changes in climate parameters would impact the final estimated values of E_r , which uses the complete set of climate parameters, and of course the final estimated C_{th} values. In order to evaluate the impact of such possible changes after 2000, the mean monthly E_r values of the grids (from the calibration set of Aschonitis et al. 2017) (Fig.2.2c) and the derived C_{th} values of the period 1950-2000 (Fig.3.1a) were extracted from the positions of the stations used for validation. These values were compared with the respective values of E_r and C_{th} that were computed with the station's raw data and correspond to posterior periods after 2000. The results of this comparison are given in Fig.4.1a, b. From Fig.4.1a, it is observed a correlation of 98% between the E_r values from grids of 1950-2000 and the E_r values from the stations using data from posterior periods. Similarly, a correlation of 98% was observed in the respective values of C_{th} in Fig.4.1b. In the case of C_{th} , there is a distinct deviation of a station where the derived C_{th} of the period 1950-2000 (value equal to 1.37) is almost half from the one observed in the station (value equal to 2.44) using its raw data. The specific station is an exceptional case since it belongs to the Centro de Investigación Atmosférica de Izaña and it is at the top of a mountain at 2371 m above sea level in Tenerife island. The specific deviation is fully justified by the fact that the C_{th} value of the grid corresponds to an area of 1 km while the specific position of the station is at a very unique

position, which can be described as the most extreme position within this pixel. There are also 3 stations in Tenerife island where the derived C_{th} of 1950-2000 are in good correspondence with those estimated by the stations. The case of Izana station in Tenerife was the perfect example for triggering further investigation for the possible effects of scale in similar environments with extremely variable topography. Investigating the individual stations with the larger % deviation of E_{ps} from E_r and the respective topography of their surrounding environment, it was observed a similar case in the CIMIS database of California stations. In this case, the larger deviations were observed in stations, which are all concentrated in the coastline between Los Angeles and San Diego. The specific region is a narrow (~20-30 km) highly urbanized coastal zone of ~200 km, which is enclosed between the coastline and a hilly/mountainous zone. In the specific stations, the average of C_{th} values of the period 1950-2000 from the position of these stations was 1.85, while the average of C_{th} values using their raw data from the validation procedure was estimated at 1.46. Apart from the large topographic variation, another reason for the C_{th} differences in these stations could be the bias that has been removed by clearing extreme flagged meteorological parameters (e.g., wind speed) in the data of California stations of CIMIS database, which are probably associated with a hurricane or other extreme events in this region. The filtering by the [Sheffield et al. \(2006\)](#) of the measurements during usual extreme phenomena (e.g., hurricanes) in the area of California, is in question for the derivation of the wind grids that were used by [Aschonitis et al. \(2017\)](#) to build the E_r grids. This could justify the fact that the gridded C_{th} values of 1950-2000 at the positions of the stations are greater than the C_{th} values estimated by their raw data from CIMIS.

Figure 4.1: 1:1 plots of (a) mean monthly E_r of grids 1950-2000 ([Fig.2.2c](#)) vs. E_r of 525 stations raw data and (b) C_{th} of grids 1950-2000 ([Fig.3.1a](#)) vs. C_{th} of 525 stations estimated by their raw data. The values of grids correspond to the same positions of stations.

4.2. Scale effects on the accuracy of the derived C_{th}

An additional analysis based only on the stations of California was made in order to show that a regional mean value of C_{th} factors may present an equivalent or even better performance from the respective local high-resolution pixel values used in the validation procedure ([Figs.3.3b, 3.4b](#)) because it may counterbalance uncertainties by the possible variability of the climatic parameters in the wider area. The reason for such uncertainties could be rainfall, which may not present significant seasonal deviations or deviations from the expected annual values for a large region but may show different spatial patterns every year within the region affecting the accuracy of the coefficients. The results of the specific analysis are given in [Fig.4.2a,b](#) for the monthly and the annual results respectively using the same value of $C_{th}=1.66$ for all stations, which is the average value of all C_{th} factors of 1950-2000 from the positions of the stations. The results of this analysis showed that a regional average of C_{th} values

can lead to similar and in some cases better performance from the respective local high-resolution pixel values used in the validation procedure (Figs.3.3b, 3.4b)

Figure 4.2: 1:1 plots of (a) of mean monthly E_{ps} (Eq.11) versus mean monthly E_r (Eq.4) and (b) of mean annual E_{ps} (Eq.11) versus mean annual E_r (Eq.4) for 60 CIMIS stations of California using the average value of their C_{th} values (i.e., equal to 1.66 for all stations) for the period 1950-2000.

4.3. Justifications about the methodology for deriving annual C_{th} correction factors based on partial weighted averages

The initial trials to derive annual correction factors C_{th} of this study were made using the average value of the twelve-monthly $c_{th,i}$ values. This procedure led to unreasonable values due to the extremely high values during winter. An example of this problem is given in the following Figure 4.3, which corresponds to a position close to Garda Lake in Italy (10.124° E, 45.45° N), where it can be seen that the monthly $c_{th,i}$ value of January is equal to 11.89. Based on the values of Figure 13, the annual average of monthly $c_{th,i}$ value for this location is equal to 2.4. Correcting the $E_{p,i}$ value of July with the factor 2.4 leads to $E_{r,i}$ equal to 338, which is 203 mm or 2.5 times larger than the respective $E_{r,i}$ of Figure 4.3. Thus, the specific procedure for deriving annual C_{th} factors was rejected.

A second approach was to use the 12 pairs of monthly E_r and E_p for each position on the grid to perform regression analysis based on the form $y = a \cdot x$ without intercept since reference evaporation $E_r = C_{th} \cdot E_p$. An example of the specific procedure based on the values of Figure 4.3 is given in Figure 4.4, where the annual C_{th} value was found equal to 0.98. The specific procedure provides annual C_{th} values, which are approaching better the higher evaporation months since the build of the methodology was aiming to reduce the error of the important/warm (in term of evaporation) months. Despite the fact that the specific procedure pays less attention to the monthly $c_{th,i}$ values of colder months, it was considered acceptable since most of the hydroclimatic applications require higher accuracy to the larger evaporation values rather to the lower ones. A similar approach was performed by Cristea et al. (2013) for deriving annual correction factors for the Priestley-Taylor method for 106 stations through the United States. The re-adjustment and the improvement of the Priestley Taylor equation based on the FAO-56 method for each specific station, only using the warmer semester of the year. The obtained optimized values of the correction factors for each station were then interpolated to produce a map of the Priestley-Taylor correction factors. For our study, the specific procedure was found to be extremely demanding in computing requirements since it was impossible to be performed pixel by pixel (777.6 million pixels) with a conventional computer unit for the whole globe using as input 24 rasters of extremely high resolution (~1 km) with a total size of ~70GB. In order to solve this problem, the method of partial weighted average (Eqs.5-10) was developed by Aschonitis et al. (2017), which provides similar results to the

regression analysis of $y = a \cdot x$ but allows to perform calculations step by step with a conventional computer unit. For the data of Figure 4.3, this method provided a C_{th} value equal to 0.99, which is almost similar to 0.98 of Figure 4.4. The specific method is also extremely efficient since it is not restricted only to the warmer semester or any other predefined periods like the case of Cristea et al. (2013) but controls all months one by one with the lower boundary of evaporation for 1.5 mm per day or 45 per month, which is more appropriate for global applications and especially for applications of high-resolution data giving the appropriate weight to the months with significant values of evaporation. The threshold of 45 mm month⁻¹ was derived empirically after analysing an extremely large number of positions in the globe (results not shown). This analysis showed that when monthly E_r was falling below 50-40 mm month⁻¹ then there was a steep increase of monthly $C_{th,i}$ (e.g. as in Figure 4.3). The reason for this increase is based on the fact that the original E_p formula is not including the combined effect of wind speed and vapour pressure deficit, which is much larger in colder months compared to the effect of temperature (Aschonitis et al., 2015, 2017). In the case where there is a location where all months show evaporation values below 45 mm month⁻¹ ($C_{th} = 0$ according to the procedure of Eqs.5-10), it is primarily suggested to use the non-zero C_{th} value of the closest location in the map of Figure 3.1a, or to use directly the original Thornthwaite without correction.

Figure 4.3: Monthly values of original Thornthwaite $E_{p,i}$ and ASCE $E_{r,i}$ method together with their respective monthly correction factors for a position close to Garda Lake in Italy (10.124° E, 45.45° N).

Figure 4.4: Simple linear regression analysis without intercept between monthly values of original Thornthwaite $E_{p,i}$ and ASCE $E_{r,i}$ from Figure 4.3.

5

Conclusions

A global grid of local correction factors for improving the performance of the temperature-based Thornthwaite evaporation method was built using gridded data covering the period 1950-2000. The method for developing the correction factors was based on partial weighted averages of their respective monthly average values, which were based on monthly ratios between the benchmark ASCE-standardized E_r method versus the original Thornthwaite E_p . This method led to annual values considering the amplitude of E_r is considering with more gravity to the monthly correction factors for the months with large E_r values, which are more important for irrigation, aridity and other water-associated procedures. The threshold of the study is also achieving to limit the estimation of unrealistic values c_{thi} that will impact a movement for the partial weighted correction factor. The values of correction factors extracted from the five major Köppen-Geiger groups (A, B, C, D, E) were investigated and showing the following order of magnitude $B > C > A > D > E$. The correction factors were validated using raw data from 525 stations of California, Australia and Europe that cover periods beyond 2000. The results showed that the corrections factors significantly improved the monthly and annual results of original Thornthwaite method E_p . The use of E_p with or without correction factors was also evaluated through the use in the aridity indices of Thornthwaite and UNEP versus the respective indices estimated based on the benchmark ASCE-standardized E_r . The results showed again that the correction factors significantly improved the performance of the indices compared to the original Thornthwaite method, especially in non-humid environments. Uncertainties in the values of correction factors were observed in regions of high topographic variability and a possible recommendation for such cases is the use of a regional average correction factor. The methods and results presented in this study and the limitations and unrealizabilities should be investigated further in future works, by focusing on: (a) the extent of the validation procedure in different areas, (b) assessment of the performance of other known empirical models that are using reduced parameters (c) use of p. w. a. method for recalibrating correction factors using the station or climate models' data of recent periods.
