IDENTIFYING MOVEMENT PATTERNS

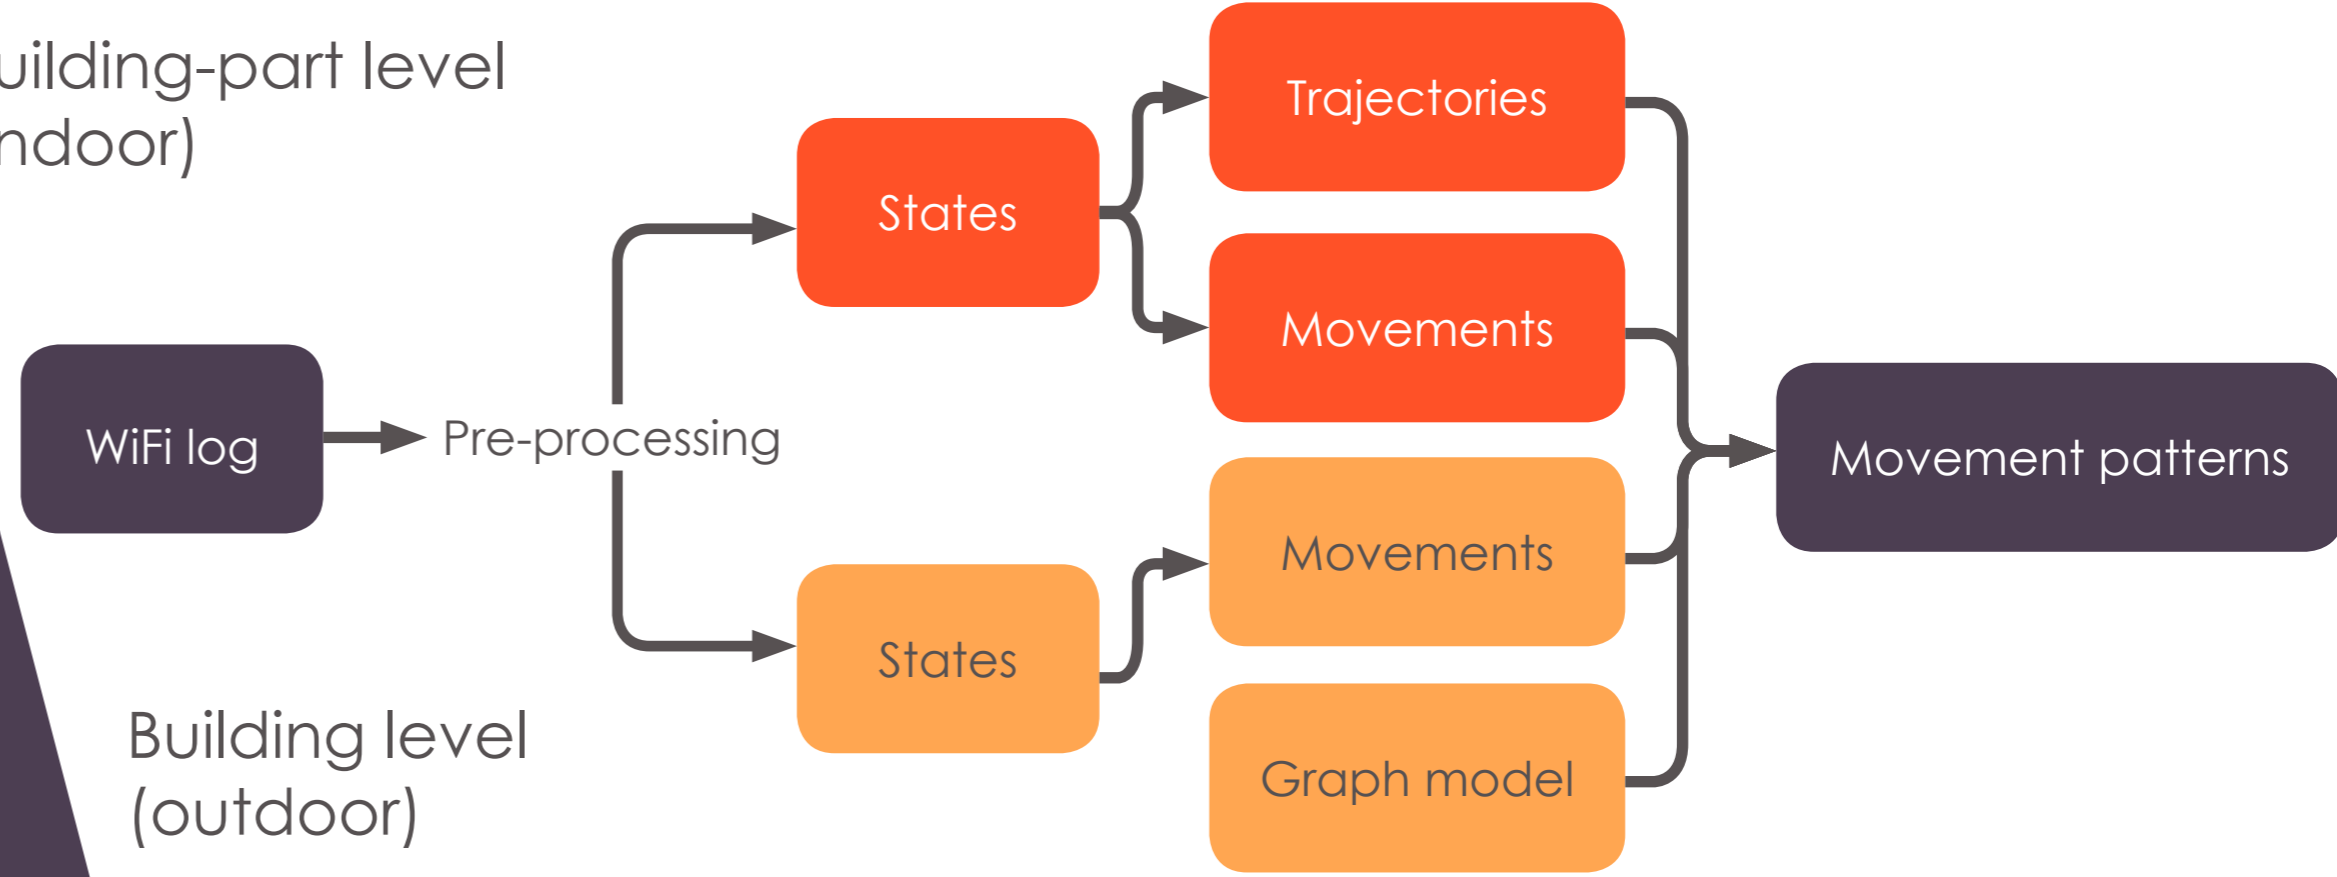

from large scale Wifi-based location data
 A case study of the TU Delft

Top movements on the campus

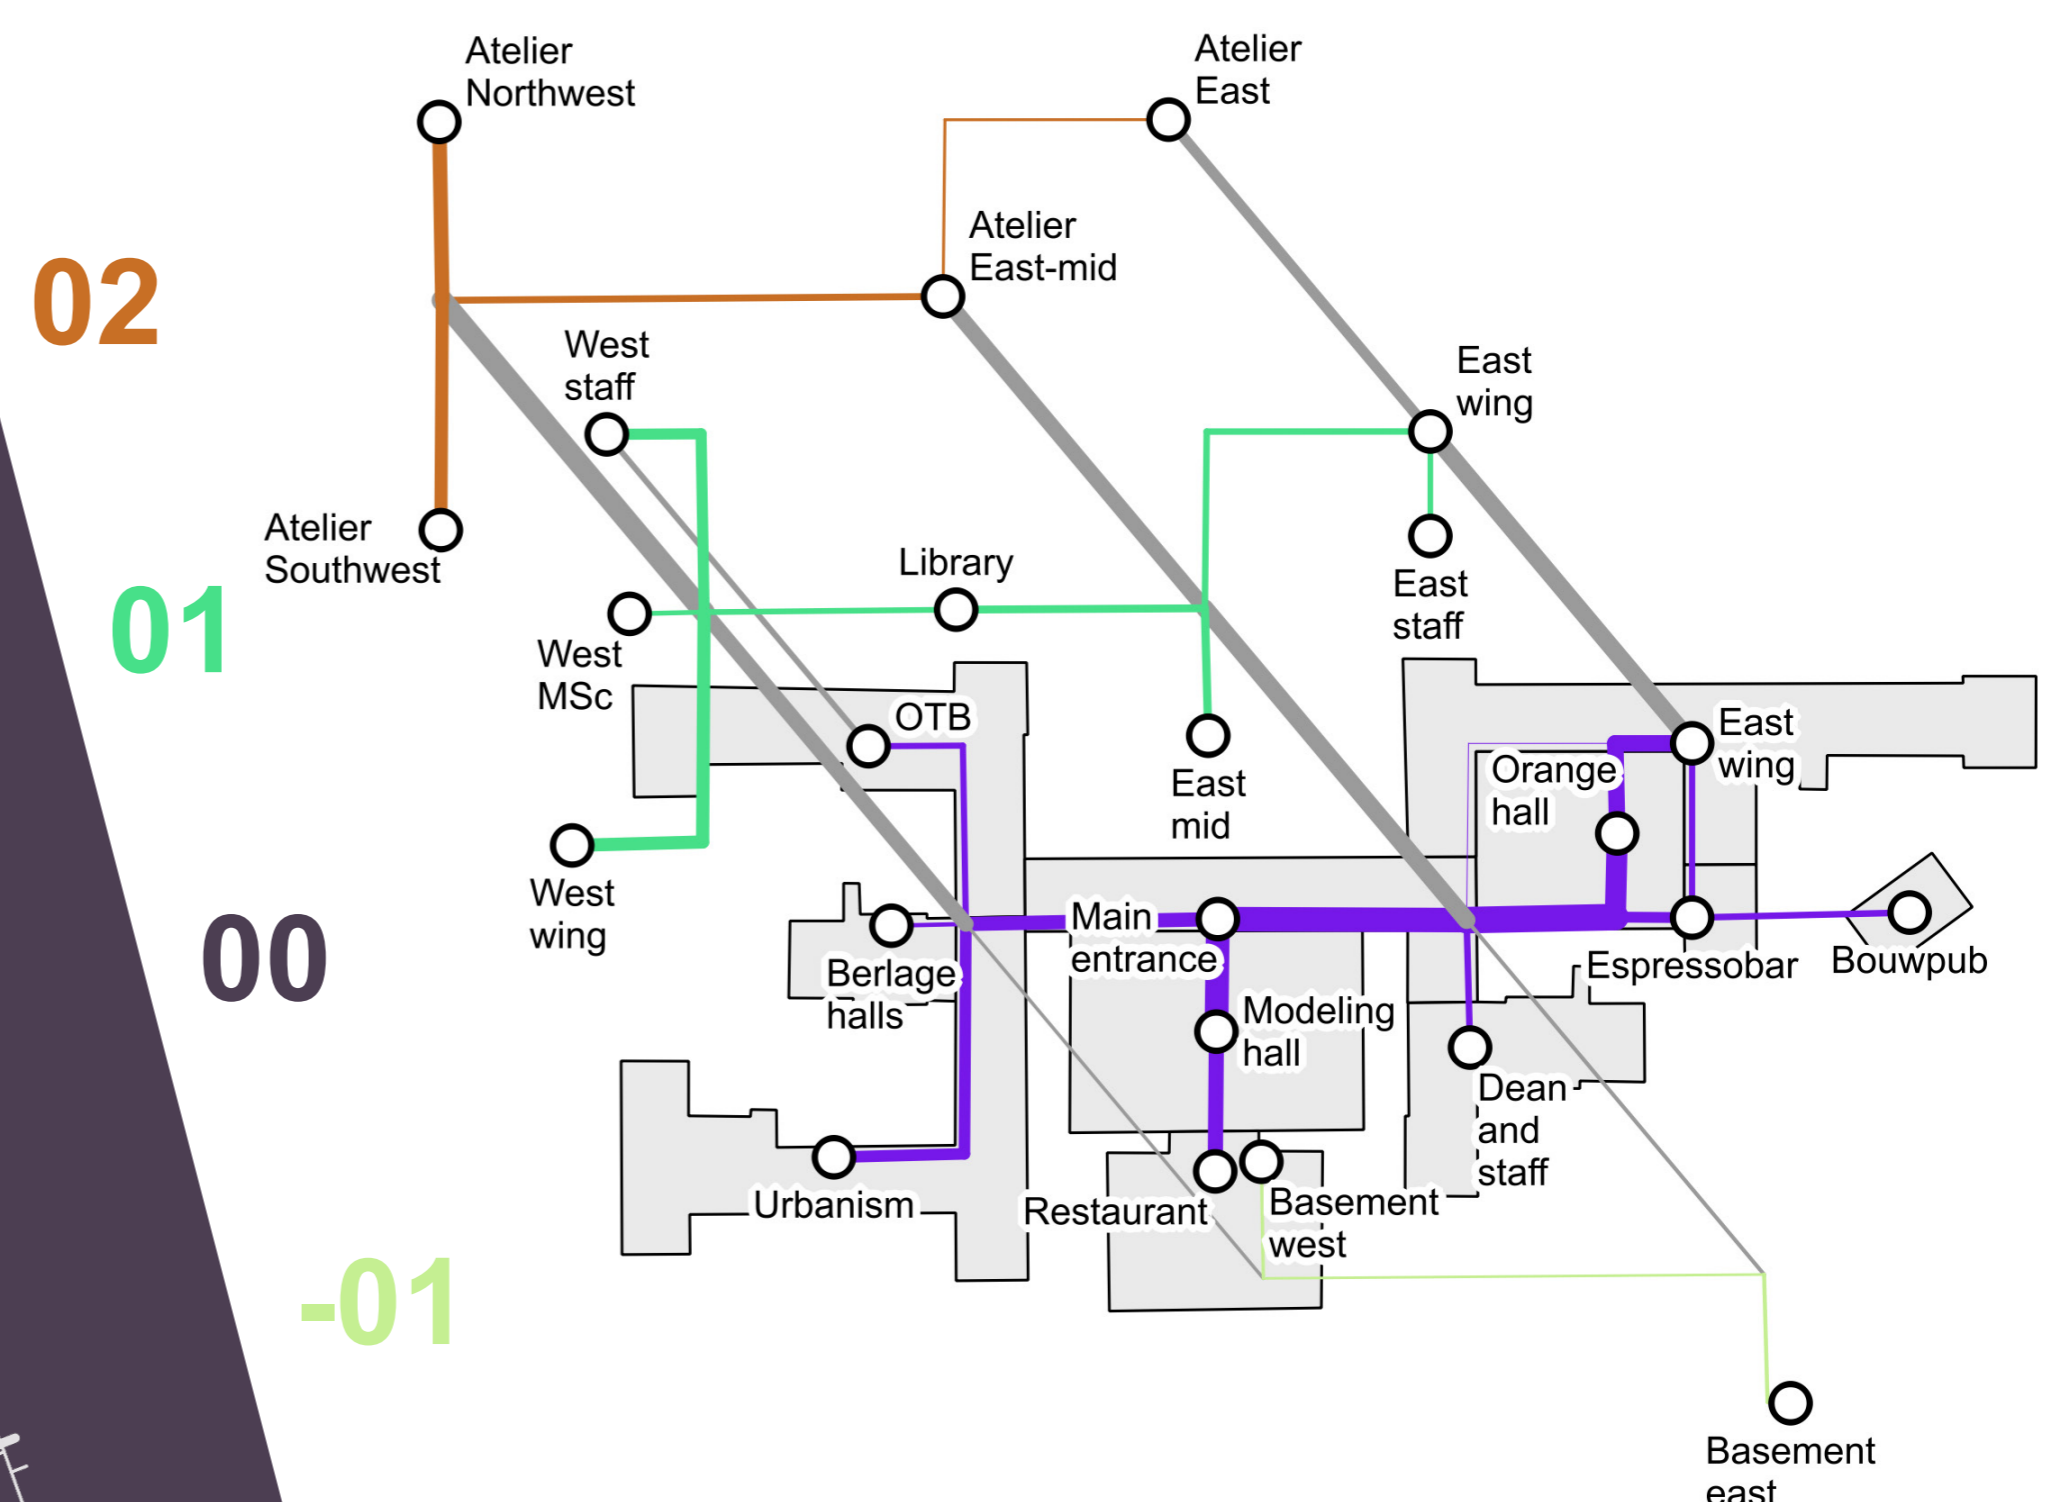

Methodology

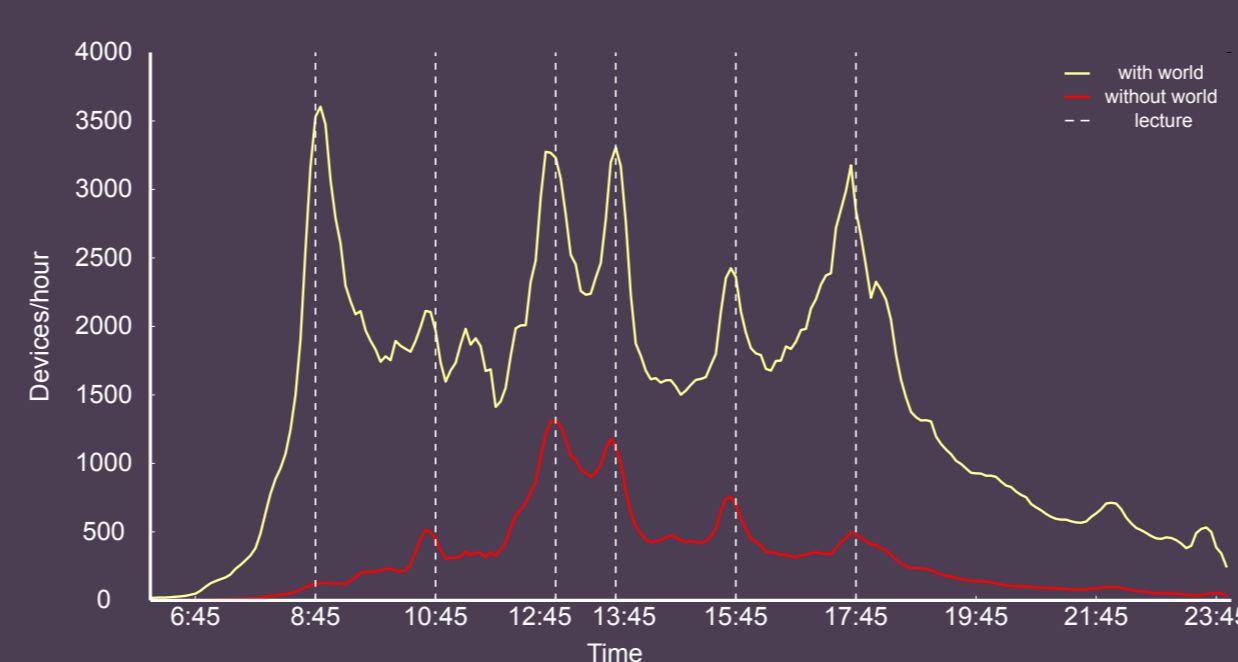

Building-part level (indoor)

Top indoor movement in the Faculty of Architecture and the Built Environment

Movement on weekdays

Research question

- To what extent can movement patterns in and between buildings be identified from large scale Wifi-based location data of the eduroam network?

Sub-questions

- What patterns can be identified moving from and to the TU Delft campus?
- What movement patterns can be identified between buildings on TU Delft campus?
- What movement patterns can be identified between large indoor regions of the Faculty of Architecture and the Built Environment?

Answers

- Movement peaks in the morning, during lunch time and afternoon can be clearly distinguished in the data corresponding to the lecture hours
- Aula-Library is the most frequently travelled path, as expected
- More specific patterns between particular buildings and/or during certain time intervals can easily be derived due to the automated workflow, such as:
 - People moving to the Aula most often origin from the faculty of Applied Sciences.
 - Aerospace Engineering and (to some extent) Architecture and the Built Environment are rather isolated compared to the other faculties on the campus.
- At building-part level, similar patterns can be identified representing the flow rate of people in the corridors. However, the range of APs can extend between building-parts and floors and limits the accuracy of the analysis.
