The logical network of potentials is realized with a physical network of traffic infrastructure across several modes of transport. Track-guided traffic routes form an essential part of the physical network, but require a reference to the associated geometric representation. At the lowest topological level, the node-edge model represents the exact physical network, while other topological models generalize it through a topological abstraction. A topology can have a geometric representation, but it does not have to. Furthermore, the representation may differ from the physical realization. For instance, the geometric representation of a station can, for example, be realized geometrically via its station building, the arithmetic center of its points or an arbitrarily set station position.

Consequently, the following requirements for a infrastructure topology can be determined:

1. The topology should consist of multiple abstraction layers.
2. The lowest abstraction layer should represent the exact physical infrastructure network.
3. Higher abstraction layers could generalize the topological abstraction of the infrastructure network.
4. Since the lowest abstraction layer represents the exact physical infrastructure network, it should be possible that an optional geometrical representation could be mapped to the layer components.

The infrastructure topology can therefore have a geometric representation, but does not have to. This representation may differ from the physical realization. The geometric representation of a station can, for example, be realized geometrically via its station building, the arithmetic center of its switches or an arbitrarily set station position. This creates a strict separation of the levels:

- The route alignment is the level of physical realization of the network
- The topology is a logical level that can reference the route alignment in a specialization, but does not correspond to it.

After this initial step of identifying the topology requirements, a topology concept will be developed that aims to fulfil them (see section "Concept of the Infrastructure

Topology"). The concept should be applicable on various data structures. For an initial prototypical implementation of the resulting topology concept the research team has decided to develop an OWL ontology. This allows for representing the topologies as graphs which are flexible to modify, especially since new edges can be added to nodes without violating previously defined data schemes. Furthermore, OWL supports logic-based modeling allowing the integration of underlying knowledge concepts and their automatic reasoning. Additionally, by using OWL as machine-interpretable standard, the resulting topology concepts can be shared and connected with other knowledge domains. For developing the prototypical ontology the Linked open terms methodology (Poveda-Villalón et al., 2022) is used, which is structured in the four steps (1) ontology requirements specification, (2) ontology implementation, (3) ontology publication and (4) ontology maintenance. For proposing the initial concept in this article, only the first two steps are processed, followed by a publication of the prototype ontology as draft. The requirements for the ontology should be the same as for the overall topology concept (see requirements 1. - 4. above). During the ontology implementation it has been considered to reuse components of OTN and RTO (see section "Related Work") directly in the newly developed ontology. However, since the structure of both ontologies differs greatly from the abstracted topology concept proposed in this paper, only the development of corresponding alignment ontologies is considered for future research.

Concept of the Infrastructure Topology

The proposed topology is an abstraction of a infrastructure network realized through logical nodes and edges that are separated from its geometric references. Therefore, the topology is defined as directed graph, which consists of the following elements:

- a set $V = \{v_0, ..., v_n\}$ of nodes
- a set $E = \{e_0, ..., e_m\}$ of directed edges between the nodes

Fig. 1 demonstrates an example of this abstract model consisting of 5 nodes and 8 edges that result in a directed graph.

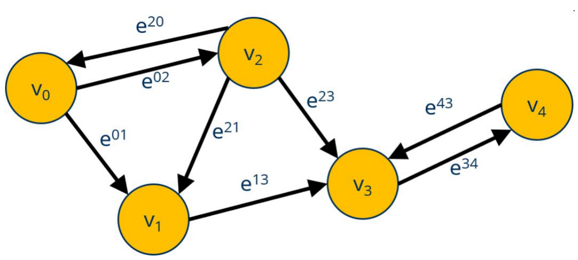

Figure 1: Directed graph consisting of 5 nodes and 8 edges

Topologically the edge $e_i := e^{jk} := (v_j, v_k)$ is unique between the nodes v_j and v_k. If there are more direct paths between v_j and v_k these are summarized topologically to e^{jk}. Through the graph the edges have access to their associated nodes and the nodes have access to their linked edges.

The proposed topology utilizes microtopologies and macrotopologies as utilized levels for abstracting a route network.

Microtopologies

The microscopic topology (microtopology) of a transportation network describes the first topological abstraction of the network from the geometry to a node-edge model. It is also the only geometric abstraction. Fig. 2 presents an exemplary microtopology of a simple switch, in which the two possible paths shown between the nodes are physically defined via the main or branch track. However, an exact geometric location and demarcation between the switch and the rest of the track can only be realized by a topological representation for the start and end of the switch. The double crossing switch results in four possible paths, only two of which are described by the alignment of the two tracks. Thus the geometric descriptions of the two additional paths are therefore required as alignments and are later assigned to the switch object.

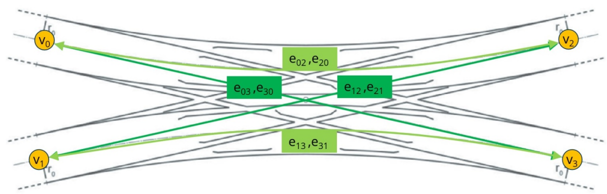

Figure 2: Exemplary microscopic topology of a single switch and a double crossing switch. The directions are indicated by double arrows. Background Figures from (Fendrich and Fengler, 2014)

If the topological decomposition of the switch is omitted, the geometric links to the physical network at these points are incomplete or only implicitly contained via the switch parameters. In addition, the switch is only positioned at a virtual intersection point, which is irrelevant for topological references back to the geometry.

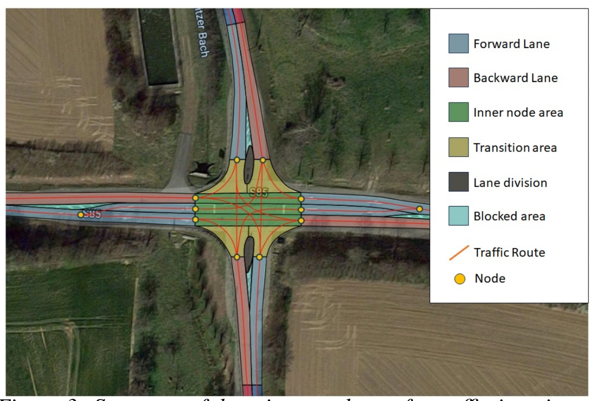

Figure 3: Structure of the microtopology of a traffic junction of two roads (Fig. from Wollschläger (2021) overlaid with the microtopological nodes)

The abstraction corresponds to the definition of junctions in road engineering. As shown in Fig. 3, there is also a strict separation between the geometric construction and the topological abstraction. The references to each other are established via nodes on the geometric lanes and edges as sections on the lanes.

Macrotopologies

The macroscopic topology (macrotopology) of a transportation network describes a topological abstraction of an existing topological network. It is therefore based on either a microscopic or macroscopic topology. It has only topological and no geometric references. Any number of macrotopologies can be constructed for a microtopology. An exemplary macrotopology is shown in Fig. 4.

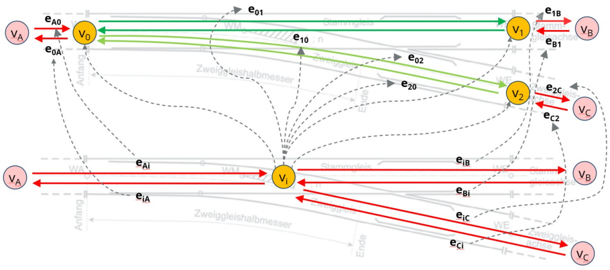

Figure 4: Abstraction of a switch as node v that aggregates nodes v_0, v_1, v_2

In the example a simple switch is defined through 3 inner nodes v_0, v_1 and v_2. According to the described data model, these nodes have back references to their linked edges, e.g. node v_0 to the edges e_{0A}, e_{01} and e_{02} with exact geometric back references.

When the microtopology is abstracted to a macrotopology, a macro node v is generated as a switch representation from the micro nodes v_0, v_1 and v_2. So that the macro node can form back references to the geometry without defining them itself, it must link all the associated micro nodes v_0, v_1 and v_2. For completeness, all inner edges e_{01}, e_{10}, e_{02} and e_{20} are also linked. Thus v itself is a directed graph.

The macro edges refer to their corresponding micro edges, e.g. e_{Ai} refers to e_{A0}, and if available their corresponding enclosed micro nodes.

All levels must be linkable with each other for a uniform, consistent topology approach. By linking them, arbitrarily abstract topology levels implicitly gain access to the underlying microtopology and thus to the physical geometry.

Structure of an OWL Topology

Based on the proposed concept of an infrastructure topology the Infrastructure Topology Ontology (INTO)[4] has been formalized using OWL. INTO provides the necessary TBox to support the modeling of microtopologies and all macrotopologies at higher abstraction levels as well as additional linking components for connecting the topology with geometry. In this regard, micro- and macrotopologies are specializations of the abstract definition of a graph consisting of nodes and edges according to Fig. 1.

Table 1 contains an overview of the prefixes used for the realization of the ontology. The prefix *into* refers to a namespace that is used by all classes and properties specifically created for INTO. In this regard, the INTO ontology uses terminology from RDFS (prefix: *rdfs*) and OWL (prefix: *owl*).

Table 1: Namespaces and prefixes used in this article

Prefix	Namespace
rdfs	https://www.w3.org/2000/01/rdf-schema#
owl	https://www.w3.org/2002/07/owl#
into	https://app.korfin.de/ontology/into#

An important implementation aspect is that edges are not formalized as OWL object properties but instead as named individuals. The primary reason for this design decision is that not only nodes are referenced by lower and higher topology abstraction levels but also edges, thus requiring a form of linking mechanism for statements. One possible solution would be the use of the RDF extension RDF-star[5], which allows the direct linking of complete RDF statements to other resources. However, RDF-star is not interpretable by most OWL reasoning engines, thus reducing the overall applicability of the ontology in an OWL context. The same applies to alternative graph models, e.g. the graph database Neo4J[6]. For this reason edges have been modelled as individuals according to the ontology design pattern "N-ary Relations"[7]. Thus, each instance of *into:edge* is connected to two instances of *into:node* via subproperties of *into:connectsToNode* but in addition can also be referenced by other instances of *into:TopologicalElement* of higher or lower topology layers. Direct connections in the form of auxiliary object properties are inferred by reasoning corresponding property chain axioms. The core concepts of INTO are shown in Fig. 5. There, each topology, be it a micro- or macrotopology, is represented as instance of *into:Topology*. Corresponding nodes (*into:Node*) and edges (*into:Edge*) are assigned to the topology trough respective object properties (*into:containsNode* or *into:containsEdge*). In this regard, the *into:Topology* instance is used as container object for storing the topological components. The actual topology is defined by assigning *into:Node* instances as start- and end-node to instances of *into:Edge* via the object properties *into:startsAtNode* and *into:endsAtNode*, thus implicitly defining the edge direction. The properties *into:startsAtNode* and *into:endsAtNode* are sub properties of *into:connectsToNode*, which is an inverse object property of *into:connectsToEdge*. Thus, by using a property chain axiom that infers the object property *into:isConnected* if an instance of *into:Node* is connected via *into:connectsToEdge* to an instance of *into:Edge* and that edge representation connects to a different instance of

[7] `https://www.w3.org/TR/swbp-n-aryRelations/` (accessed: April 03, 2024)

into:Node via *into:connectsToNode* it is possible to model direct connections between nodes through reasoning.

The symmetric property *into:inverseToEdge* allows the definition of an edge that has an inverse direction compared to another edge and thus opposing start and end points.

Both classes *into:Node* as well as *into:Edge* are subclasses of the generalizing class *into:TopologicalElement*. Furthermore, *into:Node* and *into:Edge* have additional subclasses that are used for topological elements in macro-topologies (*into:MacroNode* and *into:MacroEdge*) and microtopologies that are linked with a geometry-based alignment (*into:AlignmentNode* and *into:AlignmentEdge*).

An essential part of the proposed topological concept is the aggregation of topological elements, e.g. the aggregation of inner nodes in a macro node or macro edge. Therefore, each instance of *into:TopologicalElement* can aggregate a number of other instances of the same class via the object property *into:aggregatesTopologicalElement*. On the other hand the inverse relation via *into:isAggregatedBy-TopologicalElement* is also possible. Thus, inner nodes and edges as well as outer nodes and edges can be realized for each topological element.

OWL Realization of Microtopology

Modeling a microtopology is realized through alignment nodes (*into:AlignmentNode*) as specialized subtype of a node and alignment edges (*into:AlignmentEdge*) as specialized subtype of a common edge. These are the only types of nodes or edges, which are related to the alignment via alignment sections and thus are related to the rail geometry.

For each alignment section two alignment edges can be modeled, since in the directed, labelled graph each direction is represented through its own edge. Therefore, for each instance of *into:AlignmentEdge* a reference to the respective instance of *into:AlignmentSection* is necessary as well as a definition of the direction via the data property into:direction.

OWL Realization of Macrotopology

Macrotopologies are defined via macro nodes (*into:MacroNode*) as specialized subtype of nodes as and macro edges (*into:MacroEdge*) as specialized subtype of edges. Macro nodes and macro edges connect respectively the corresponding nodes and edges of lower topology levels. For simplified calculations, the inner nodes are separated from the outer nodes and the inner edges from the outer edges in a macro node. A macro edge also has this separation, although it cannot have any outer nodes. Macro nodes and macro edges describe an independent, directed, labelled graph.

Thus infrastructure elements can be separated and abstracted from each other. The alignment is abstracted topologically via the microtopology including mapped switches. A topological track plan could be obtained by merging the switches into macro nodes and defining the connecting macro edges. For example, if the macro nodes of all points of a station and possible multi-tracks between the stations are summarized in macro edges, it would be possible to get Line network plans. Furthermore, it is possible to determine comprehensive network maps by combining stations into agglomerations in further macro nodes as well as combining routes including "intermediate stations" into macro edges.

Connecting Topology with Geometry

To define the topological node-edge model independently from the underlying geometry, additional linking elements are used (see Fig. 7). The core elements for this are alignment sections (*into:AlignmentSection*) and alignment stations (*into:AlignmentStation*), which define the alignment positions. Instances of both of these classes can be assigned to an instance of *into:Alignment* that represents the alignment via the object properties *into:partAlignment* for linking alignment sections and *into:containsStation* for linking alignment stations. Additionally, an inverse object property of *into:partOfAlignment* named *into:dividedBy-Section* could be utilized in the modeling process.

An alignment section is defined through a start station and end station both positioned on the same alignment. Therefore, instances of *into:AlignmentStation* are assigned to an *into:AlignmentSection* instance via the properties *into:startsAtStation* and *into:endsAtStation*. Since the stations are defined as OWL individuals they can be reused in the modeling process, e.g. the end of an section is usually the start of the next section on the same alignment.

The configuration of an alignment section consisting of multiple sub-sections from different alignments, which could happen for example through different planning sections or sectional remeasurement, could be realized through a specialized alignment that is linking multiple alignment sections.

Thus the geometry reference is completely described and independent of the geometric construction, i.e. the topology can be defined at any point on the geometry.

The proposed concept can be generalized to point and line objects. Consequently, an instance of *into:AlignmentSection* represents a special line object and an instance of *into:AlginmentStation* a special point object. The further topological view is limited to the geometric reference, which is also defined by the generalization. Via property chain axioms alignment sections can also be assigned automatically to alignments if they define the start or end of a corresponding alignment section.

The connection between the alignment section and the topology is realized through linking instances of *into:AlignmentSection* and *into:Alignment* with micro edges realized through *into:Alignment*. Therefore, the object properties *into:assignedToSection* and *into:assignedToAlignment* are used. Furthermore, the relation *into:assignedToAlignment* between *into:Alignment-Edge* and *into:Alignment* can be inferred if the respective instance of *into:AlignmentEdge* is connected to an in-

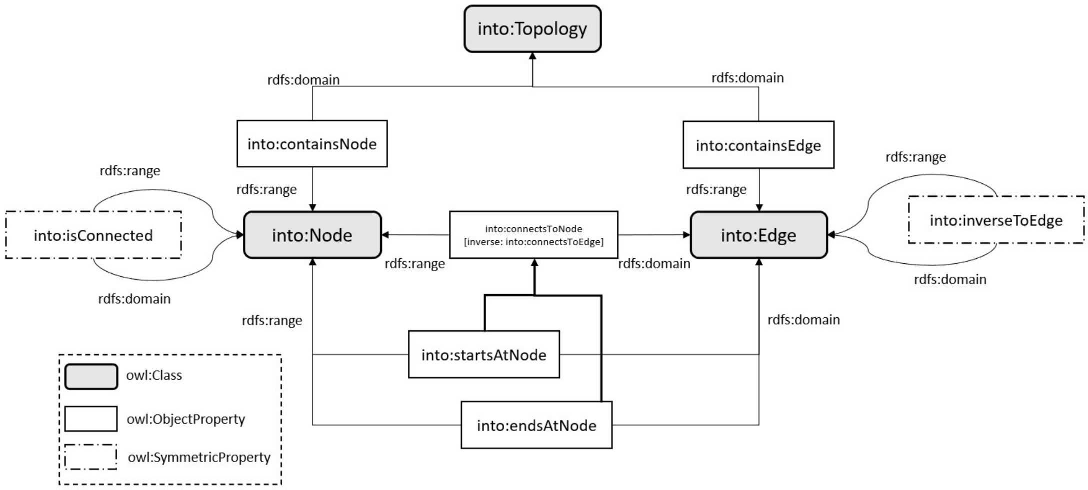

Figure 5: Core concepts of the topology part of the proposed OWL ontology

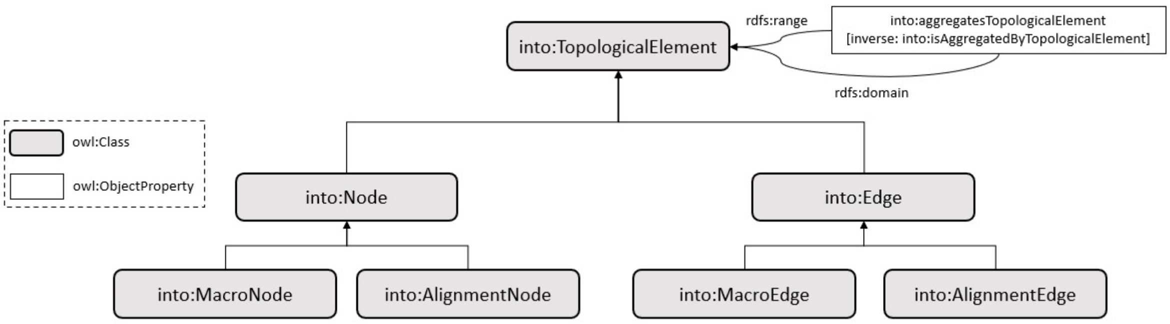

Figure 6: Inheritance concept for topological components

stance of *into:AlignmentSection* via *into:assignedToSection* and that representation of alignment section is linked to into:Alignment via *into:partOfAlignment*. The geometric data can either be linked directly in the OWL graph by using auxiliary ontologies such as the File Ontology for Geometry (FOG) (Bonduel et al., 2019) or by defining a separate link model, e.g. a linkset in an Information Container for Linked Document Delivery (ICDD) according to ISO 21597. Additionally, further management of the alignment representation could be utilized via the Ontology for Managing Geometry (OMG) (Wagner et al., 2019).

Application of the OWL Topology

To demonstrate the developed ontology an exemplary abstraction between two topological levels to represent a simple rail switch have been modeled as ABox using the TBox described in the previous section. The structure of the switch is the same as shown in Fig. 4. The topology example has been modeled as OWL ontology and uploaded in a locally hosted GraphDB[8] triplestore. Fig. 8 shows a graph visualization whereby the focus node is v_i.

By reasoning the modeled assertional graph (Abox) that stores all factual information against the terminology (TBox) of the INTO Ontology, aggregations of topological elements of the macro topology towards a microtopology can be inferred and vice versa. For instance, for the nodes v_0, v_1 and v_2 the outer node v_i has been automatically inferred if v_i assigned these nodes as inner nodes. Furthermore, all inner edges e_{01}, e_{10}, e_{02} and e_{20} are also linked. Consequently, v itself is a directed, labelled graph. By processing the graph in a reasoning engine direct connections (*into:isConnected*) can be inferred for all nodes that belong to the same edge. For example, v_0 is connected to v_1 and v_2, while v_1 and v_2 share no connection with each other.

For a high-performance evaluation of the node at runtime, it is advised to set up a path matrix across all outer nodes of the macro node, i.e. a statement whether v_1 can be reached via v_2. However, this is not part of the ontology model.

The macro edges refer to their corresponding micro edges, e.g. e_{Ai} refers to e_{A0}, and if available their corresponding enclosed micro nodes.

[8] https://graphdb.ontotext.com/ (accessed: April 03, 2024)

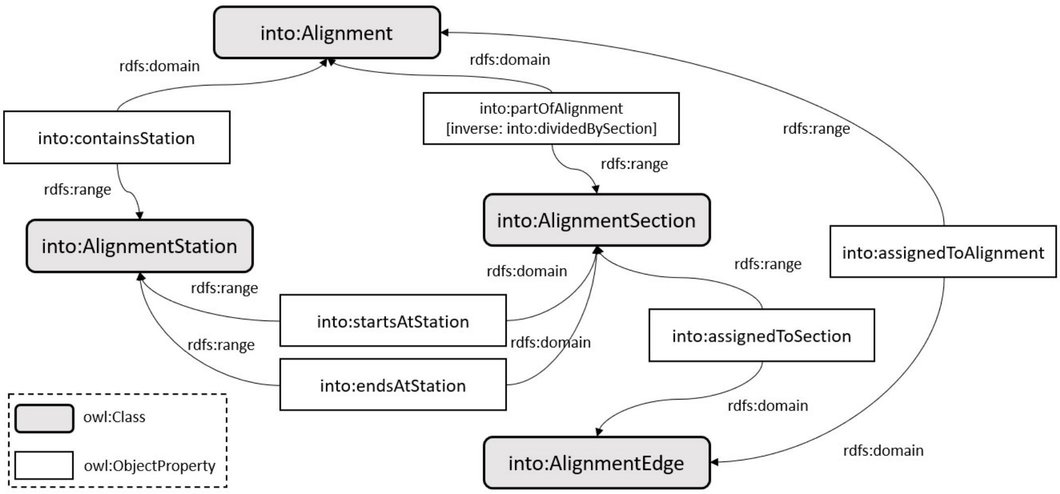

Figure 7: Concept for ontological alignment representation

The presented concept can also be used recursively for all higher-level macrotopologies.
In general the abstraction of the ontology involves the following steps:

1. Definition of the nodes and edges to be abstracted, so that the necessary nodes and edges can be clearly assigned to a higher abstraction level in a node-edge model.
2. Creation of the new macro nodes and internal structure by referencing the associated nodes and edges.
3. Creation of the new macro edges and of the inner structure by referencing the associated nodes and edges.
4. Linking the new macro nodes and macro edges via the back references of the outer nodes and edges.
5. Temporary creation of path matrices for macro nodes and macro edges via the inner structures.

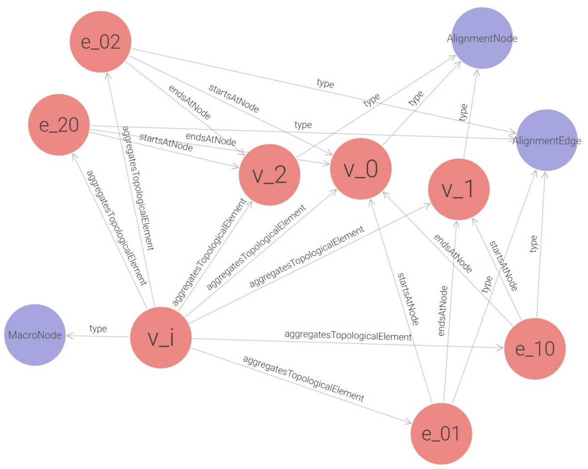

Figure 8: OWL ontology example in GraphDB

Based on the requirements defined in the "Methodology" section various SPARQL queries could be applied that make use of the topology structure and inference mechanisms to provide information about the infrastructure network and validate the ontologies functionality. For instance Query 1 identifies elements of higher and lower abstraction layers for a set of topological elements.

Listing 1: SPARQL Query for Topological Aggregation

```
SELECT ?element ?lowerElement ?higherElement
WHERE {
  {
    ?element into:aggregatesTopologicalElement ?
         lowerElement .
    OPTIONAL {
      ?element into:isAggregatedByTopologicalElement ?
           higherElement .
    }
  }
  UNION
  {
    ?element into:isAggregatedByTopologicalElement ?
         lowerElement .
    OPTIONAL {
      ?element into:aggregatesTopologicalElement ?
           higherElement .
    }
  }
}
```

Based on the requirement that the lowest abstraction layer should represent the exact physical infrastructure network, queries for selecting information about instances of *into:AlignmentEdge*, e.g. in Query 2 could be applied. Thereby, Query 2 is used for determining the starting and ending station of each alignment edge. A similar query could be applied for instances of *into:AlignmentSection*.

Listing 2: SPARQL Query for Alignment Edges

```
SELECT ?edge ?start ?end
WHERE {
  ?edge a into:AlignmentEdge ;
          into:startsAtStation ?start ;
          into:endsAtStation ?end .
}
```

Conclusions

In this paper a concept for a topology that represents traffic nets has been proposed. In addition a corresponding prototypical ontology has been formalized in OWL and illustrated in an example of representing a simple switch.

The topology can be structured in multiple abstraction levels. In this regard two level types are used: (1) Microtopologies that describe the traffic net at the lowest abstraction level and reference to a geometric representation and (2) Macrotopologies that describe a higher topological abstraction of the traffic net and therefore are based on lower microtopologies or macrotopologies. An important aspect is that multiple macrotopologies can refer to the same microtopology in parallel for various use cases, allowing the use of domain specific topologies for e.g. train transportation or route junctions.

One key aspect is that edges are not classified as OWL object properties when modeling the topological concept in an ontology. The main reason for this is that individuals that represent edges need to reference other edges in order to abstract the topology in multiple levels of different hierarchies. A combination of RDF-star and OWL has been considered but was not applied due to inference issues when processing the ontology in an OWL reasoning engine.

The topology can be used in various user scenarios. For example, a model for data exchange can be made available for traffic flow analyses and simulations. The topology can also act as the foundation of further BIM-supported infrastructure planning by providing a basic geometry-independent model. It is subject of future research how the developed ontology could be aligned with other ontologies used in infrastructure and construction planning, e.g. the Bridge Topology Ontology (BROT) (Hamdan and Scherer, 2020) or the Rail Topology Ontology (Bischof and Schenner, 2021). Furthermore, geodata ontologies such as the GeoSPARQL Ontology (OGC GeoSPARQL Standards Working Group, 2024) could be utilized for georeferencing the components of the topology. In order to ensure the practicability of the topology concept and the ontology, both developments must be applied in comprehensive test cases as part of future research.

AIPDORCS: ARTIFICIALLY INTELLIGENT PRELIMINARY DESIGN OF REINFORCED CONCRETE STRUCTURES

Alon David Argaman and Rafael Sacks
Technion – Israel Institute of Technology, Haifa, Israel

Abstract

Leveraging 106 engineers' expert assessments of preliminary structural design in 48 reinforced concrete building models, we compiled two experimental Graph Neural Network (GNN) tools to demonstrate feasibility for automated classification of structural schematic layouts, a key step toward building generative artificial intelligence (AI) tools for design. Contributions include a robust project database, a model-to-graph conversion tool, and a structural design scoring application. Acknowledging limitations related to modelling assumptions and a relatively small dataset, this research clarifies the opportunity and the obstacles to AI-driven advancements in preliminary structural design.

Introduction

The construction industry has seen remarkable advances in computational tools, from 3D modelling to finite element analysis. One critical aspect has remained relatively untouched: the preliminary design phase, a creative step where engineers propose conceptual structural layouts using heuristic rules (Caprani, 2009). Despite the availability of sophisticated tools for detailed design, the quality of results is often constrained by suboptimal preliminary designs. While optimization algorithms like genetic algorithms are available for engineering design (Katoch et al., 2021), they face challenges in execution simplicity, adapting to changing standards, and precise programming. This research explores whether deep learning can be used at the preliminary design stage to simulate the experience of senior engineers, offering faster, cheaper, and more accurate solutions. Focusing on reinforced concrete (RC) structures, we address the scarcity of AI applications in preliminary design, particularly within the construction industry (Afzal et al., 2020). The research aims to leverage recent developments in AI and machine learning to better automate the preliminary design process, with a specific focus on structural plans classification.

Background

Engineering Design and Automation

Engineering design, a creative and iterative process, has seen a surge in automation using AI techniques, aiming to enhance efficiency, reduce costs, and improve design quality. Expert systems, an early AI development in the 1970s and 1980s, simulated human decision-making by using a knowledge base, and were applied in various engineering fields to make decisions and solve problems (Rychener, 1988). However, the emergence of more advanced AI algorithms, such as machine learning, neural networks, and deep learning, has surpassed the limited use of expert systems (Medsker, 1995).

The AEC (Architecture, Engineering, and Construction) industry has witnessed significant advancements in AI applications, notably in architectural layout design and generative design. The use of Generative Adversarial Networks (GANs) for architectural conceptual design (As et al., 2018), floor plan generation through rectangular dual finding algorithm (Wang et al., 2018), and automated apartment plan generation using genetic algorithms (Laignel et al., 2021) exemplify the industry's adoption of AI. AI's influence extends beyond architecture to construction, with applications like predicting labour costs (Huang and Hsieh, 2020), estimating assembly costs of flooring systems (Elhegazy et al., 2022), and employing Deep Convolutional Neural Networks (CNNs) for automated assembly of lunar construction components (Zhou et al., 2020). Start-up companies like “FIRMUS” (Abecasis and Amar, 2019), “Daisy” (Selvaraj et al., 2019), and “Structure Plus” (Jozi et al., 2019) further demonstrate the feasibility and effectiveness of incorporating AI in the AEC industry, enhancing design efficiency and optimizing structural elements.

Artificial Intelligence and Structural Design

Over the years, AI has advanced significantly, and the integration of Building Information Modelling (BIM) has become commonplace. The rationale for employing AI in preliminary structural design is rooted in the recognition that this phase demands substantial creative input, combining engineering expertise, wisdom, and judgment (Samuel and Weir, 1999). While traditionally deemed difficult to simulate with rule-based tools, recent developments showcase the ability of advanced tools, such as Artificial Neural Networks (ANNs), to emulate these qualities by drawing inspiration from human brain neurons and incorporating engineering experience through prior data collection. Noteworthy applications include the use of ANNs for tall building design (Anwar et al., 2015), design response grammars and evolutionary algorithms for conceptual layouts creation (Boonstra et al., 2020), and reinforcement learning for optimizing plane frames (Hayashi and Ohsaki, 2020). Recent examples span diverse areas, such as accelerating the exploration of shell structure topological design (Zheng et al., 2020), designing RC columns with ANNs surpassing traditional design charts (Charalampakis and Papanikolaou, 2021), automating shear wall design for residential buildings using a method called StructGAN (Liao et al., 2021), and recommending early-stage structural design with minimal errors (Ampanavos et al., 2022). These advances collectively highlight the potential of AI to revolutionize the structural design phase, offering expedited and precise design solutions while minimizing costs and computational resources.

BIM and Graph-based Representation of Structures

Building Information Modelling (BIM), introduced in the seminal article "The Use of Computers Instead of Drawings in Building Design" (Eastman, 1975), has evolved into a crucial platform for detailed geometry exploration, interference resolution during early design stages and more, as evidenced by a study on modular housing design (He et al., 2021). Parametric design, integral to BIM, involves defining model families or element classes with rules controlling parameters. This approach facilitates the integration of AI in structural design by enabling computers to comprehend and control structural models. Unlike humans, computers rely on parametric objects, aligning with the principles of object-oriented programming. While the IFC schema (ISO 16739-1, 2018) is the standard for BIM data exchange, challenges persist, leading to inaccuracies and information loss (Sibenik and Kovacic, 2020). Recent solutions, such as invariant signatures (Wu et al., 2021a), and semantic enrichment via machine learning (Bloch and Sacks, 2018), aim to address these issues. Additionally, a shift towards graph-based representation in structural design, exemplified by studies like structural optimization using genetic algorithms and ANNs (Chang and Cheng, 2020), indicates a growing trend in data processing methods, offering potential for further exploration and improvement.

Graph Neural Networks in Engineering

The advantages of graphical representation in BIM models lead to proposal of GNNs for reliable and efficient structural design using AI. GNNs, introduced in 2009 (Scarselli et al., 2009), have demonstrated significant power in various domains, such as financial networks and molecular structures (Xu et al., 2022). Practical applications of GNNs in fields like internet traffic optimization (Bernárdez et al., 2023), stock classification (Xu and Zhang, 2023), and predicting microbe-disease associations (Jiang et al., 2023) are emerging. In the context of BIM models, which inherently possess complex relationships and dependencies, GNNs offer a natural solution for their non-Euclidean structure (Wang et al., 2021). Notably, the Graph Convolution Network (GCN) appears promising for classifying graphs representing BIM models, leveraging convolution to learn from node connections, akin to classical CNNs but tailored for graph structures (Wu et al., 2021b).

Gaps in Knowledge and Research Aims

Despite advances in graphical representation-based AI applications, those learning directly from human input remain absent. Moreover, the scarcity of solutions for AI-driven preliminary building design, emphasizes the need for research in this crucial domain (Huang and Fu, 2019). Employing the Design Science Research (DSR) methodology (vom Brocke et al., 2020), this study aims to show the feasibility of automated preliminary classification of structural plans using GNNs and engineers' experience. In other words, can AI effectively learn from the experience and expertise of human engineers through a combination of BIM models and engineer surveys? Answering this research question involves developing a tool that transforms basic BIM structural models into actionable information, enabling accurate classification based on a knowledge base of pre-labelled engineers' structural plans.

AIPDORCS Concept

Interviews were conducted with five senior structural engineers, each with at least a decade of experience, to establish existing preliminary design practices. The resulting process was meticulously mapped in a BPMN diagram, summarizing the preliminary design process from the architect's requirements until the completion of all preliminary design tasks by the structural engineer, as shown in Figure 1. Interestingly, the interplay of architectural requirements and structural solutions matches Maher's model of co-evolutionary design (Maher and Poon, 1996). This visualization underwent validation by eight senior structural engineers. The engineers

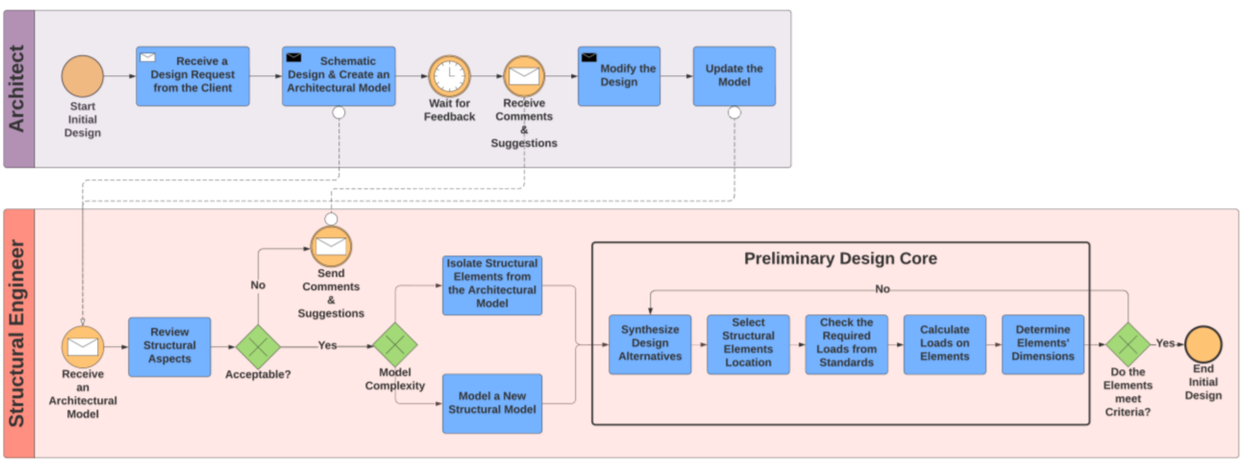

Figure 1: The process of Preliminary Structural Design, BPMN diagram.

emphasized the iterative nature of the process, likening it to a Taylor series, where each step contributes to convergence. They revealed diverse preferences in material selection, structural elements, and evaluation methods, showcasing the complexity of design choices. Notably, the interviews underscored the absence of a singular truth in structural design, with engineers prioritizing factors differently. A new concept emerged from this nuanced understanding, aiming to enhance the structural design process through AI by incorporating diverse insights and automating key aspects. We call this new concept "*AIPDORCS*", an acronym for *"Artificially Intelligent Preliminary Design of Reinforced Concrete Structures."* This concept comprises three stages, as shown in Figure 2. The first stage, *Data Collection & Preparation*, involves collecting and preparing data, converting structural plans into appropriate formats, addressing challenges in BIM model collection by utilizing 2D plans, and creating structured data tables for graph construction, all of which are essential for training a GNN model in the subsequent stage. The second stage, *Structural Plans Classification*, focuses on training the GNN model through engineer surveys, employing data tables and structural plans obtained from BIM models. Finally, the third stage, *Structural Design Generation*, delves into employing optimization algorithms like genetic algorithm or deep learning to evolve and refine solutions based on the previously trained classifier, iteratively until achieving optimal engineering solutions. The first two stages are the focus of this study.

AIPDORCS Development (Stages 1 and 2)

Structural Plans Collection

Initial attempts to gather the vast amount of data needed for training the supervised learning model, i.e. acquiring BIM models from large engineering firms, faced challenges due to legal and copyright issues. Requests for schematic plans also met with limited success. An alternative approach involved leveraging academic resources – final project plans from undergraduate students. These plans, encompassing diverse structures, were obtained with permissions from graduates, yielding 201 approved plans. The variation in quality within student designs proved advantageous, offering a spectrum for training the AI model. Subsequently, a database was constructed, filtering out non-relevant plans and ensuring anonymity by removing personal information. This database comprised around a hundred structural plans, predominantly in PDF format.

Plans to Models

Structural plans in PDF or DWG format were deemed unsuitable for training the GNN model based on engineers' experience, due to their lack of essential information. The chosen solution involved manual conversion of 2D plans, of typical residential and commercial buildings, into intelligent 3D BIM models using Autodesk Revit software (Autodesk, 2022). Recognizing the absence of flawless automatic conversion applications, a meticulous workflow was developed for manual modelling, addressing challenges of human error and maintaining a clean, uniform model database.

The modelling process started with loading a premade template into each project, resolving scale issues, and utilizing Autodesk Revit's "Snap" tool to identify and correct discrepancies. The modelling workflow included distinct steps for modelling walls, columns, beams, and slabs. Each element type was carefully modelled, considering specific rules such as ignoring windows and small openings, simplifying door modelling, addressing various complexities in columns, and modelling a separate slab for each space. Completing the models included crucial steps like "Join Geometry" automation for correct connectivity between structural elements, element numbering for referencing, manual checks by the researcher to ensure database quality, and sheet creation for later survey reference. Each model was assigned the following global parameters: building function, number of floors and gross height. Plans deemed unsuitable for the study, such as bridges or small houses, were excluded. In total, 48 projects were modelled.

Models to Data

In the transition from BIM models to usable data, Dynamo (Autodesk, 2020), a visual programming language for Autodesk Revit, was employed to automate the conversion process into structured CSV files. The feature engineering aspect of this stage focused on creating an equal number of features for each structural element. Geometric properties such as dimensions in three directions and volume were considered, avoiding redundancy. Noteworthy is the decision to exclude element location coordinates, deeming them unnecessary for preliminary design as the focus was on the geometry of elements and their connections.

Feature engineering aligned with accepted design practice, was primarily based on the calculation of the "limitation of slenderness." A uniform assumption of 30 MPa concrete with limestone aggregate was made for all elements. The Dynamo script categorized objects into groups of nodes, which facilitated the extraction of global parameters, adjusted gross height, and extracted geometric properties and connections for beams, walls, columns, and slabs. Unique challenges arose in feature engineering for columns, where complex cross-section shapes were converted to equivalent rectangular cross-sections. Similarly, for slabs, irregular shapes were converted to equivalent rectangular slabs based on the largest inscribed circle's diameter, and the distance of the slab's centroid from nearest vertical support elements.

In total, each CSV file extracted for each structural element type included three geometric dimensions, volume, automatically numbered element ID, and a list of connections to different elements, forming a foundation for subsequent analysis and classification stages.

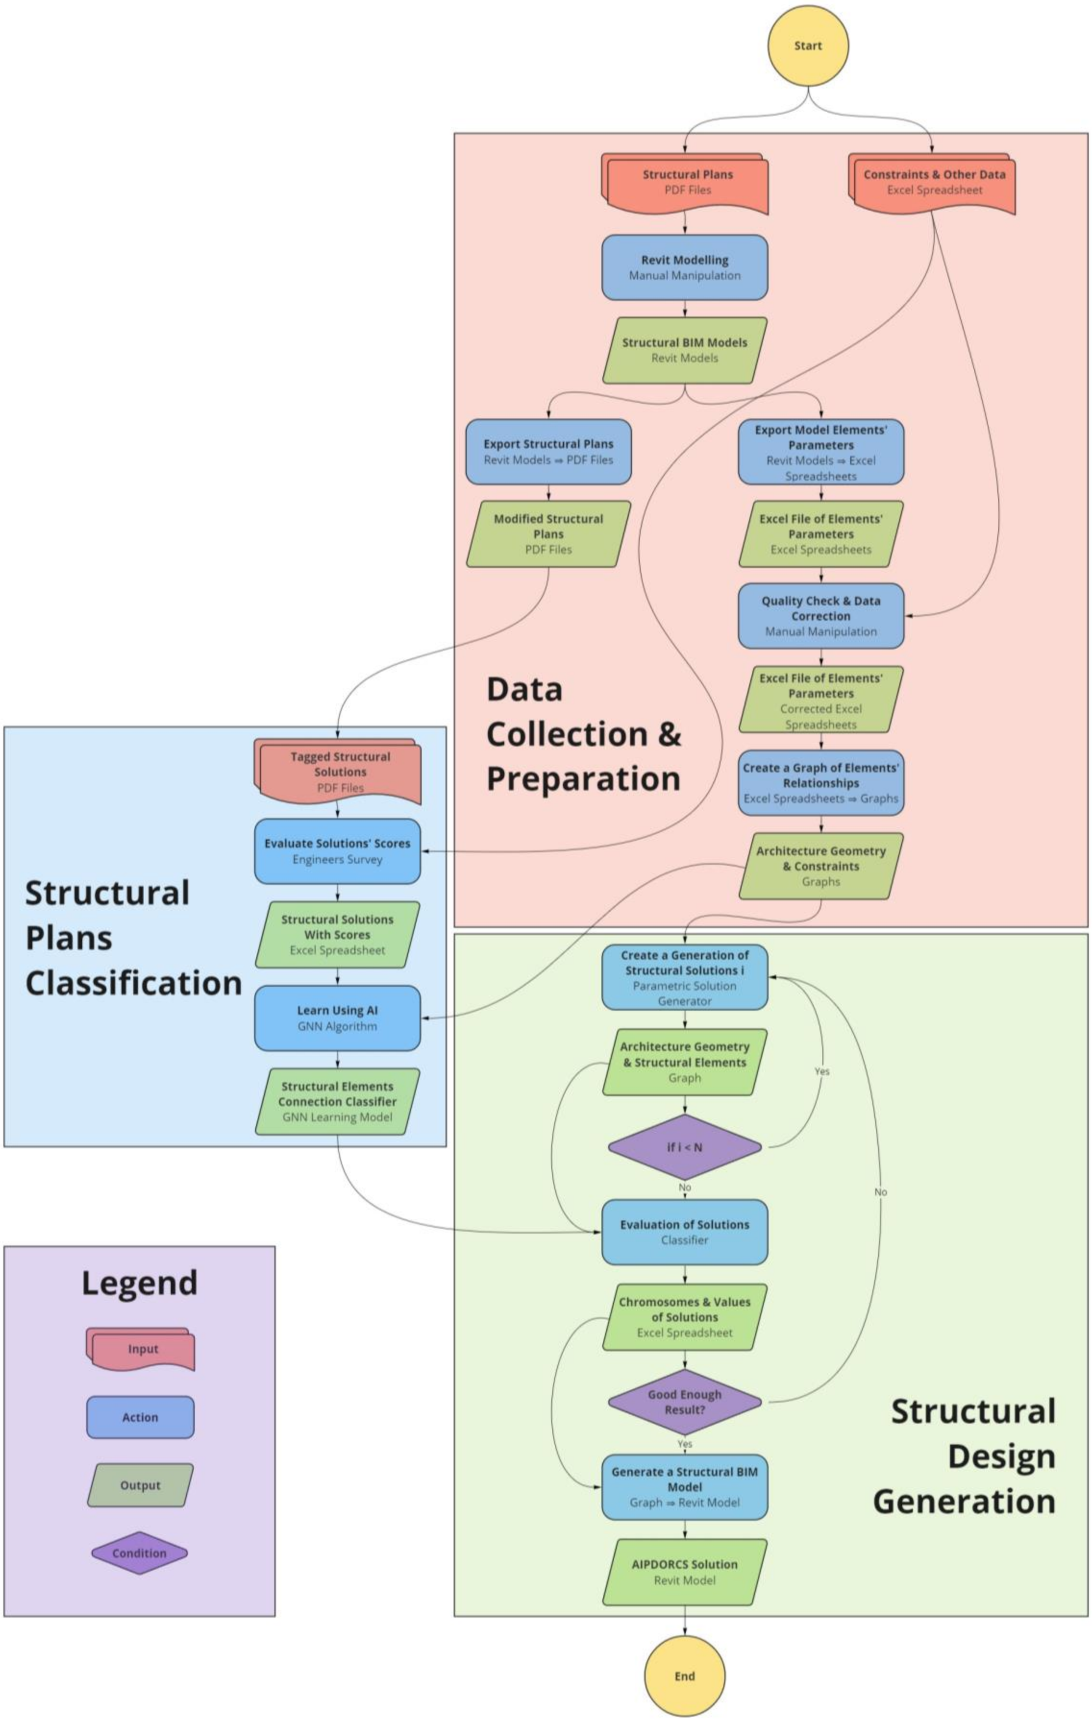

Figure 2: AIPDORCS Concept Diagram

Engineers' Challenge

The *"Engineers' Challenge"* online portal was compiled to facilitate labelling of structural plans for training the GNN model. Structural engineering experts were asked to use the portal to review plans presented to them at random from the set of 48 projects, and to give scores to the overall design and to annotate the individual design elements with their design critique (by selecting design faults from a list). The result was a comprehensive dataset for automated structural design with AI.

Compilation of the portal tool required identifying the critical aspects of preliminary structural design, designing an effective and efficient user experience, and considering engineering discretion while crafting questions. Given the unique nature of the survey – requiring feedback on 48 distinct structural plans – back-end project database management and user interface considerations were paramount. No available survey compilation tool could satisfy the requirements, and thus the portal was programmed from scratch utilizing JavaScript through the Wix API (Velo, 2006).

The portal's dialogs cover project data, element comments, and general comments with an overall score. The survey is available online at the AIPDORCS's website (Argaman, 2020). Note the addition of comment properties to each element, improving results by incorporating engineering aspects such as cross-sectional area, cost, simplicity of execution, and element slenderness. Users could provide feedback on specific elements, offering a comprehensive view of the structural plans. Moreover, the general comments allow users to review the global plan as a whole, considering comments such as 'inadequate vertical support', 'uneconomical design alternative' and 'implementation difficulty'.

The survey generated valuable responses, with 112 feedbacks obtained, including scores for all 48 models. The results and analysis of the survey contributed significantly to the subsequent stages of the AIPDORCS process.

Data to Graphs

At this stage, we utilized Python routines to construct a graph database for training the GNN model using CSV files from Revit models and *Engineers' Challenge* responses as input. To form graphs from the CSV files, preliminary data consolidation and processing were required. Each structural element from each BIM model is represented as a graph node containing features derived from exported CSV files. The natural and error-free conversion involved creating a file listing all elements as graph nodes with their respective features, incorporating both geometric and survey properties.

Creating graph edges, representing connections between nodes, was a more intricate process. The edges capture the relationships between structural elements. Given that the graph is homogeneous, i.e. all elements shared the same number of properties and dimensions, we could represent all structural elements with a single node type, named "Structural Element", as shown in Figure 3. This figure also illustrates the graph creation process from BIM models, focusing on a segment of *Project 001* from the AIPDORCS database.

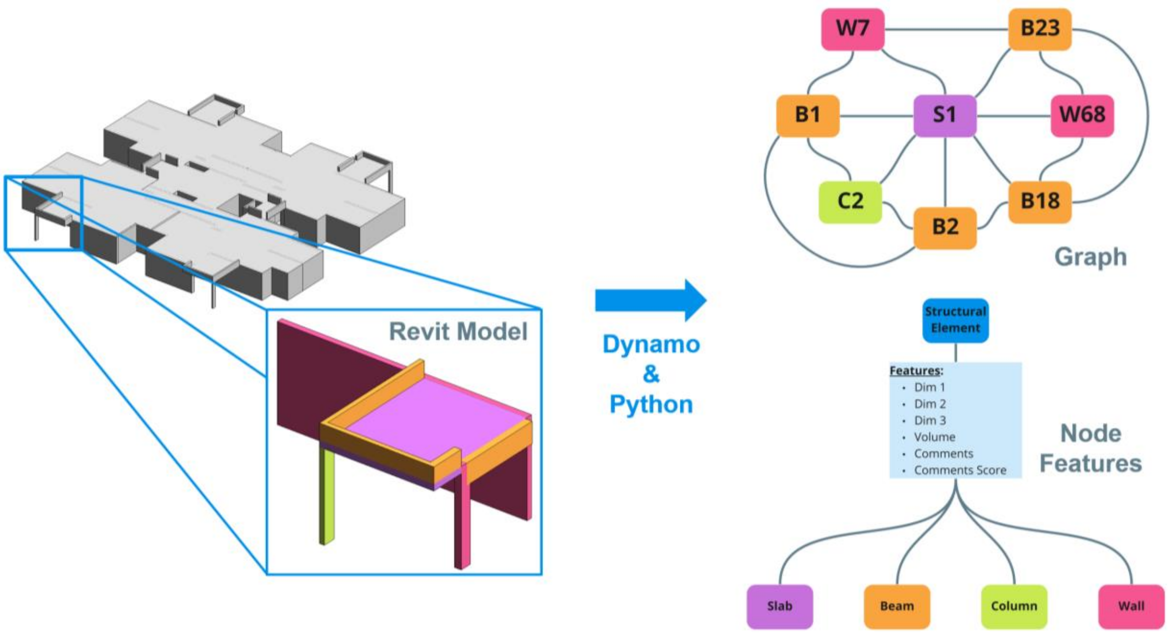

Figure 3: An illustration of the graph creation process, based on Project 001's BIM model

The Python code for this stage is organized into three files:

1. *data2graph*: The main file, orchestrating the process of building a graph database from CSV files.
2. *classes*: Defines classes for structural elements, graph nodes, and graph edges, adhering to object-oriented programming standards.
3. *websiteData*: Manages functions related to extracting and processing information from the *Engineers' Challenge* CSV file.

The code follows object-oriented programming standards, ensuring readability and maintainability for future research, and appears on AIPDORCS GitHub repository (Argaman, 2022). It uses standard Python libraries for data science, with a focus on DGL (Deep Graph Library, 2018) for creating graphs and training the GNN model.

Upon running the code, graphs are generated, exemplified by Figure 4, which shows the graph extracted for *Project 001* from the BIM models database. This visual representation exhibits element numbering and their geometric connections, providing a means for validation against the original structural plans.

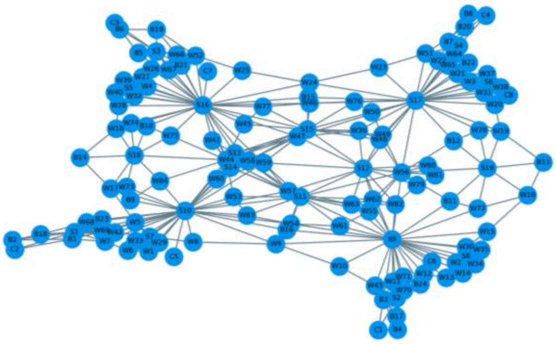

Figure 4: Graph of Project 001's BIM model

Graph Neural Network

Two experiments were conducted utilizing GNNs, or more specifically GCNs, for classifying structural design plans with a pass/fail grade according to a certain threshold. Experiment 1 was based on geometric model graphs, where 48 graphs correspond to 48 projects, with graph nodes containing only geometric features (four features: Dim 1, Dim 2, Dim 3, and volume). Figure 5 shows the ANN structure of experiment 1.

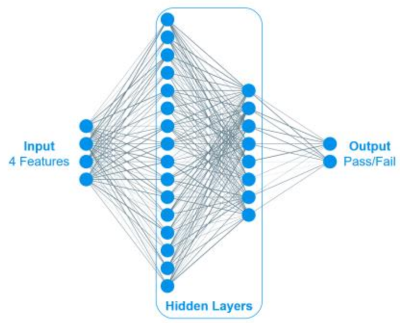

Figure 5: Experiment 1 artificial neural network structure

Experiment 2 is based on engineering feedback graphs, where 106 graphs correspond to 106 valid portal responses, with graph nodes containing all 14 features (geometric properties, survey comment properties, and points subtracted for comments). Figure 6 illustrates the ANN structure of Experiment 2.

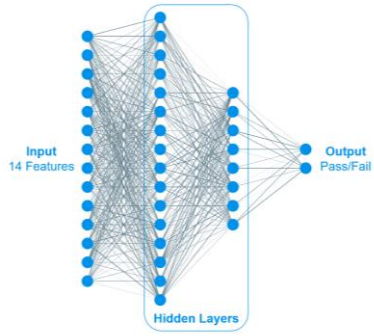

Figure 6: Experiment 2 artificial neural network structure

The architecture of the networks for both experiments is illustrated in Figures 5 and 6 respectively. The networks are structurally identical, with variations in the number of features in the input layer based on the experiment. Careful experimentation and evaluation are essential in determining the most suitable hyperparameter values for achieving the best results, and avoiding overfitting. In both experiments, the output labels were the *Engineers' Challenge* overall scores, converted to a binary value by the average score threshold. The data was split to an 80% training set and a 20% test set, and the following hyperparameters were selected by testing and tuning: number of hidden layers: 2, hidden dimensions: 16, activation function: ReLU, learning rate: 0.005, and number of epochs: 200.

Results

Engineers' Challenge

A total of 112 responses were gathered through the portal, six of which were deemed invalid and filtered out. The analysis of the survey results revealed insights into the engineers' perspectives and highlighted their attention to specific elements, as well as the distribution of feedback across different categories.

When comments were given on specific elements, the majority of engineers provided an average of three comments on each, demonstrating a conscientious approach to the task. Additionally, 58 written comments, categorized as "Additional Comments", required manual conversion to relevant element features, showcasing the depth of insights shared by engineers. The distribution of element comments illustrates that issues related to the size of the element's cross-section were the most frequently noted, emphasizing the significance of this aspect in the eyes of experienced engineers.

Furthermore, analysis of overall scores revealed a predominantly positive trend, with most models receiving scores above 70. Outliers with lower scores were investigated, leading to the identification and correction of errors in feedback or potential typing mistakes. The survey results also prompted an examination of the relationship between the extent of engineers' years of experience and the scores they assigned. The findings suggested a deviation in scores based on experience, with less experienced engineers tending to give higher scores. However, the scores did not exhibit a consistent trend, emphasizing the need for further data collection to draw more conclusive insights. Overall, the *Engineers' Challenge* portal provided a valuable dataset for understanding expert opinions on structural plans, laying the groundwork for subsequent experiments with GNNs.

Experiments

The outcomes of the GNN experiments exhibited variability across runs, influenced by both the inherent randomness in the code and the model's instability arising from limited data in the database. Focusing on the most promising runs, the analysis employed standard data science performance metrics, derived from a binary classification's confusion matrix: Accuracy, precision, recall, and F1-score.

Table 1: Experiments performance comparison

	Accuracy	Precision	Recall	F1 Score
Experiment 1	60.0%	57.1%	80.0%	66.7%
Experiment 2	68.2%	75.0%	88.2%	81.1%

The results, detailed in Table 1, highlight Experiment 2's superior performance compared to Experiment 1 across all metrics. The larger dataset and richer feature set in Experiment 2 contributed to its enhanced precision, recall, F1-score, and overall accuracy. These findings underscore the potential of GNNs in structural design classification, suggesting that leveraging extensive and diverse datasets can significantly enhance the performance of GNN-based classifiers, offering promising prospects for their application in preliminary structural design assessments.

Discussion

The AIPDORCS concept introduces an innovative approach, setting it apart from existing works in the realm of structural engineering. Integrating AI with human expertise, this concept redefines the preliminary structural design process, offering a unique solution. In the modelling phase, which produced 48 BIM models, opportunities for improvement were identified. They included refining geometric connections and expanding the features of structural elements, which would yield a heterogeneous graph. Unequal scoring patterns revealed in survey responses necessitate further considerations, like re-scoring based on comments and normalizing scores by engineers' experience clusters. The structural plan classification experiments yielded promising results, particularly with the utilization of engineering feedback graphs, showcasing the potential of leveraging survey data for precise structural design classification. However, employing 5-fold cross-validation emerges as a key recommendation to ensure dataset representativeness, detect overfitting, and bolster model generalization.

The technical and research limitations present crucial aspects to address. Technical limitations, such as support for specific building patterns and materials, indicate areas for improvement and expansion. Research limitations, including a small dataset and a limited number of feedbacks, underscore challenges related to generalizability and robustness. Issues like varying scales of overall scores and limited time and resources further emphasize the complexities and constraints of the study. While the two initial experiments offer valuable insights, the need for additional experiments on a larger and more diverse dataset is recognized. Notably, the use of comments as features in Experiment 2 prompted consideration of the applicability of this approach in a real-world AI tool. These limitations shape the context of the study and offer directions for future research, emphasizing the need for a comprehensive and conclusive evaluation of the proposed approach for scoring structural plans using GNN.

Conclusion

Through the execution of two experiments utilizing GNNs, this study established the basic feasibility of automating structural plans classification, underscoring the potential to enhance accuracy and efficiency in the design process. Nevertheless, further research work is required to reliably answer the research question. Acknowledging concerns among engineers about AI's role in the creative phase of design, this study emphasizes a collaborative approach, asserting that AI can augment human capabilities without replacing them. The concluding sentiment draws inspiration from Charles Darwin's principle of adaptability, encouraging engineers to embrace AI's transformative potential in structural design, foreseeing a future where the integration of AI not only optimizes processes but also fosters innovation.

This study contributes to the field of civil engineering by proposing the AIPDORCS concept, innovatively transforming BIM models into GNN-ready graphs. Additional contributions encompass the development of a robust database, an automated model-to-graph solution, and a scoring program for structural plans. These innovations offer valuable resources, time-saving tools, and educational applications, positioning the research at the forefront of AI-assisted structural design. To conclude, this research marks a valuable step toward a future where AI and human expertise harmoniously shape the landscape of structural engineering.

MULTI-STAKEHOLDER INFORMATION REQUIREMENTS TO SUPPORT LIFE CYCLE ASSET MANAGEMENT

Conor Shaw[1], Flávia de Andrade Pereira[1,2] James O'Donnell[1]
[1]School of Mechanical and Materials Engineering and Energy Institute, University College Dublin, Ireland
[2]University College London, United Kingdom

Abstract

The current IT paradigm in the built environment is misaligned with sustainability policy. Previously proposed ontologies for Asset Management, such as life cycle analysis, lack complete concepts to cater to a wide stakeholder group. This paper describes a more comprehensive asset management software landscape. It details the initial development steps using the Linked Open Terms methodology including requirements gathering and ontology conceptualisation. A modular ontology landscape is proposed including top-level, domain-wide concepts and modular, application-specific concepts; a scenario suited to the particularly broad domain needs.The work fosters consensus in the domain and we propose alignment/extension with the existing RealEstateCore standard.

Background

The future of asset information management

In line with sectoral goals to reduce emissions in the built environment, various policy mechanisms exist. These include emissions target-setting, as well as a trajectory towards mandatory reporting on how efficiently assets and organisations use resources throughout their lifetime. Examples include the recent Corporate Sustainability Reporting Directive (European Commission, 2023) aimed at organisations generally, as well as the EU's ambitious Level(s) framework (European Commission, 2022) focused specifically on the built environment. Additionally, within financial markets, the value of a building is increased in investors' eyes by obtaining environmental certifications (such as LEED, BREEAM etc.) which evaluate lifetime performance around various metrics. This phenomenon reflects a shift in values where high-consumption, environmentally unfriendly assets become a business risk in a decarbonised future (Dumrose and Höck, 2023). In this context, Asset Managers (AMs) play an important role as the discipline tasked with operating and maintaining built assets, particularly throughout their in-use phase where the majority resources are consumed (Geekiyanage and Ramachandra, 2018). As a result, AMs have a significant influence on the sustainability and resulting value of buildings and infrastructure.

AMs rely on various indicators to make value-based decisions and assess the operational performance of facilities, evaluating decisions by balancing cost, risk and performance (Fang et al., 2022). This approach aligns conceptually with the Life Cycle Sustainability Assessment (LCSA) methodology which evaluates an asset through a holistic financial-social-environmental lens (Figure 1). LCSA provides a comprehensive view of an asset's resource consumption over its entire life, enabling evidence-based decision making supported by long-term value rather than solely focusing on short-term, or initial investment costs (Kehily and Underwood, 2017). This approach contrasts with the typical practice which tends to prioritise immediate investment expenses, often neglecting the broader implications of decisions over time (Grzyl et al., 2017), a tendency which, according to Collier (2018), is part of a much wider phenomenon of short-term-ism in the financialised built environment and current workings of capitalism. To conduct LCSA analysis using IT systems, AMs require structured information about facilities; however, this information is frequently unavailable due to the widely-recognised inadequacy of current information management practices (Gao and Pishdad-Bozorgi, 2019). Additionally, the software required to perform these insightful analytics is often unsuitable. Existing LCSA applications tend to be either too costly, lack the flexibility to meet specific stakeholder needs, or simply be unavailable altogether (Shaw et al., 2024). As a result, AMs currently rely on laborious, error-prone, ad-hoc analyses to support their decisions. Consequently, the potential benefits of LCSA are not being widely realised.

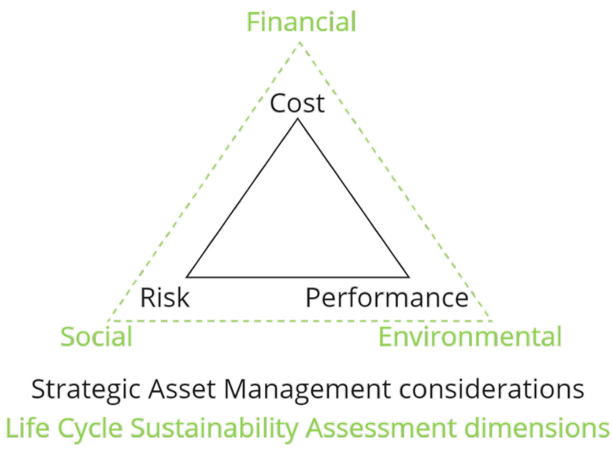

Figure 1: Conceptual overlap between AM decision-making and the holistic LCSA methodology

Ontologies can be used to organise domain knowledge in a formalised manner within IT system, facilitating information management and automation through inheritance and logical reasoning. Furthermore, ontologies can impart consensus semantic meaning to data shared over the web, referred to as Semantic Web Technology (SWT), a direction suggested by experts in the field as a necessary next step in LCSA research given the data-intensive nature of the practice (Salvado et al., 2021). A further advantage of information management using SWT is the potential for extensibility for specialised stakeholder needs. Given the expansive scope of AM activities, this is a logical requirement of a future-oriented IT landscape.

Previous efforts in AM-related ontology development

ISO 15978 (European Committee for Standardization (CEN), 2011) establishes a widely-agreed taxonomy of asset lifecycle phases. It serves as a foundational framework for much of the work in information management to support LCSA activities, involving the classification of costs and resources per phase. In accordance with the standard numerous applications and ontologies have been developed catering to various LCSA-related use cases (Lu et al., 2021), of which relevant works are now discussed.

In terms of envisioning software landscape, recent work by Sobhkhiz et al. (2021) emphasises the necessity of leveraging SWTs, enabled by ontologies, to address the substantial data handling challenges inherent in LCSA. The authors demonstrate the efficiency gains achieved over traditional relational database methods. Other studies, such as Wilde et al. (2022) and Ghose et al. (2022), focus on establishing a foundational, or top-level ontology, to support LCSA activities. These studies enable stock-level analysis, and consequently, the outcomes of these efforts do not support AMs in operational-level decision-making. In the pursuit of multi-scale analysis and aggregation, a recent work of significance is the SLiCE data model by Röck et al. (2024) which supports analysis from individual materials and parts, through building-level and up to the stock-level. Given the broad scope of AM functions, it is reasonable that achieving consensus on a universally shared ontology for the domain remains a challenge; however, the above initiatives are clearly progressing in this direction.

Another promising development are consolidation and alignment activities between standards communities. Xie et al. (2022) propose alignment between the BOT and BRICK ontologies. Their FDM ontology establishes a top-level asset information management concept for data integration in an effort towards a Digital Twin paradigm in future. Hammar et al. (2019) pioneered the development of a now widely adopted ontology tailored for asset owners, with a focus on concepts relevant to smart building applications and tenancy/leasing. Their collaborative effort, backed by a consortium of major asset owners in Sweden, aimed to establish shared domain use cases and describe these in the RealEstateCore ontology. The standard boasts a large user base and actively engages in alignment activities with other leading domain ontologies like Brick (for building automation systems) and BOT (for topological building description),

A number of efforts are of note which address specific analytical AM use cases. On the maintenance side, Katsumi et al. (2022) utilise the Ontology Requirements Specification Document (OSRD) development methodology to identify user requirements for a common AM ontology, drawing from a specific water treatment plant case study. Though focused on maintenance work orders, the study demonstrates a related ambition towards consensus that could potentially align with our own efforts at a later stage. Of particular relevance to our specific objectives of conducting multi-criteria LSCA analysis is the research by Gao et al. (2020) which proposes the LCCA Ontology, tailored for generating machine-learning-based financial life cycle cost predictions at the building level. Though publicly available, this ontology may be overly specific to its application context and not readily adaptable to the granular level of detail required for AM decision making.

Synthesis and research method

This body of research showcases a promising, future-oriented evolution toward effective asset information sharing on the web. However, none of the existing studies have comprehensively addressed multi-stakeholder needs for implementing LCSA-informed AM applications, with a particular gap in operational phase capabilities. A harmonisation of these efforts will be crucial for supporting decision-making and reporting processes in future given the broad expanse of AM activities, and it is promising to see a recognition of this in the active alignment efforts in the community. To this end, the Linked Open Terms (LOT) ontology development methodology (Poveda-Villalón et al., 2022) provides a structured approach for gathering domain requirements for a future ontology landscape. This paper describes our initial steps in this direction, following the research activities as illustrated in Figure 2.

Information requirements to support life cycle asset information management

The following information requirements derive from a combination of research activities. These include extensive reflection on the domain literature, as described in the previous section, supplementary interviews and discussions with AM practitioners and ontology developers, and from our previous practitioner-based research in AM decision-support system development (Shaw et al., 2024). In that study we developed a software prototype and reference architecture to support AMs with a number of fundamental use cases relating to financial life cycle cost analysis. The remainder of this paper builds upon this domain insight, and illustrates our perspective on future AM system requirements to support life cycle asset management more broadly, including a concept for the arrangement of top-level and modular application ontologies.

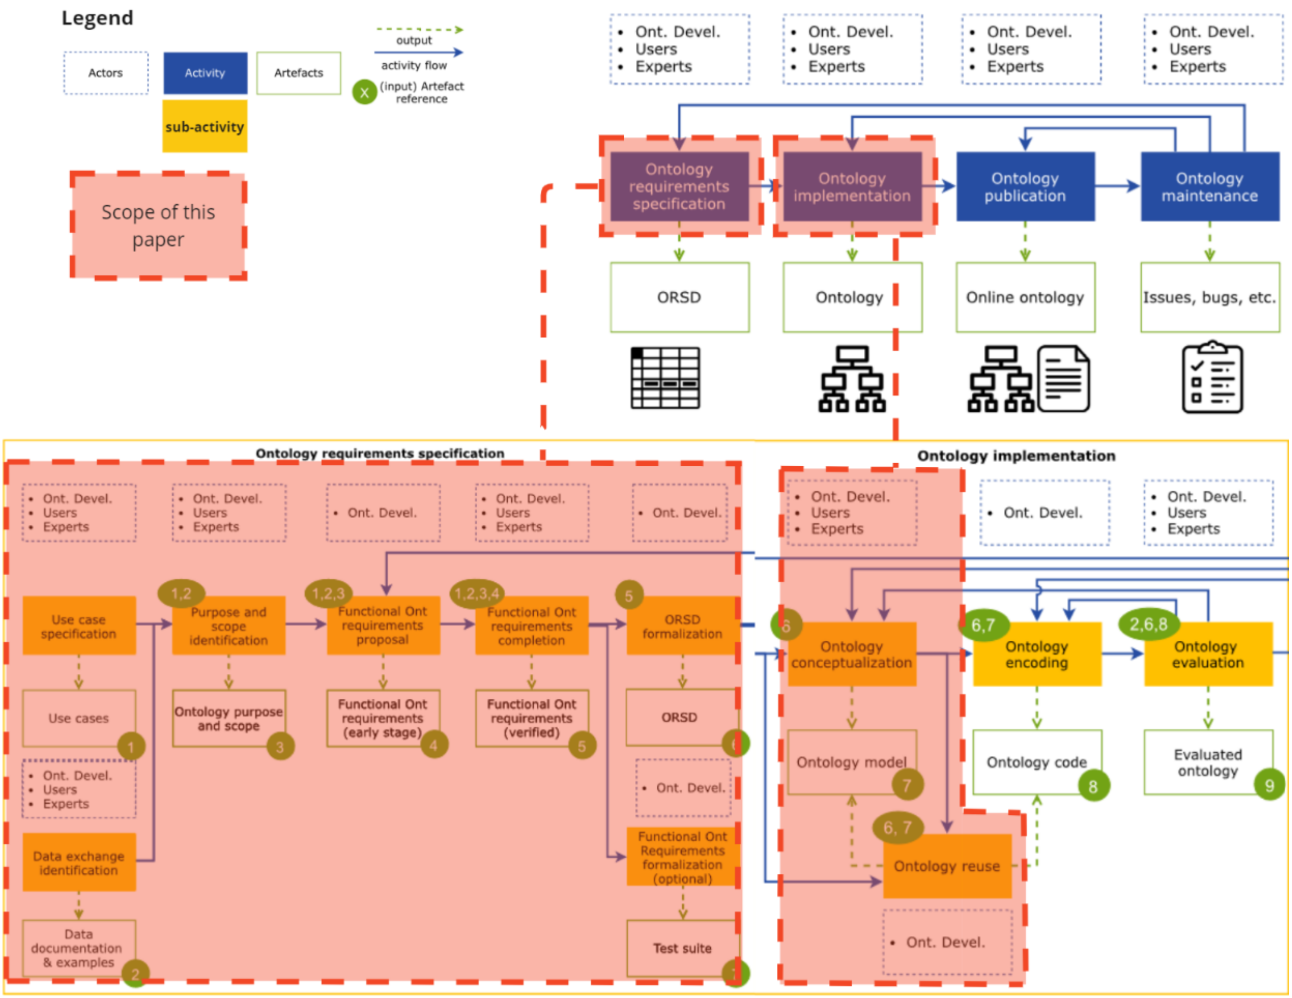

Figure 2: Paper scope - adapted from the generic LOT ontology development methodology, described by Poveda-Villalón et al. (2022)

Concept and use case specification

We envision a democratised IT landscape, and a departure from the current inflexible, proprietary software paradigm. This web-based system should be highly customisable (or *extensible*) to specific user needs, but with a foundational, shared top-level ontology which formalises domain knowledge and logic in line with international standards. Due to the data-intensive nature of the LCSA activities, a main purpose of the system is be to integrate inputs over the web, via either data warehousing or mediation, as set out by Xie et al. (2022). In this way, multiple stakeholders from diverse disciplines could make use of the structured information to suit their specialised analytics needs using additional modular, application-specific ontologies. The modularity and Microservices concepts are described by Pritoni et al. (2021) and Werbrouck et al. (2023), respectively, and our system architecture concept is presented in Figure 3. For the purposes of this study, and in line with the LOT methodology, the following use cases are suitably representative of the multi-stakeholder needs for the asset life cycle information system.

- ***Use Case 1:*** Life cycle analysis at various levels of granularity and across various indicators (ie. finance, energy, condition)
- ***Use Case 2:*** Decision-alternative analysis (or *optioneering*)
- ***Use Case 3:*** Performance gap analysis (against a baseline - supporting performance-based contracting)
- ***Use Case 4:*** Reporting in line with policy frameworks (the EU's Level(s) methodology, for example)

Non-functional requirements

- ***Purpose:*** The system architecture concept aims to define fundamental information categories for life asset management and analysis applications, offering standardised terminology and relationships to integrate information from diverse IT systems and sources.
- ***Scope:*** Both the top-level and modular application-specific ontologies are widely generalisable, ensured by their being based on international standards and remaining relatively abstract and extensible.

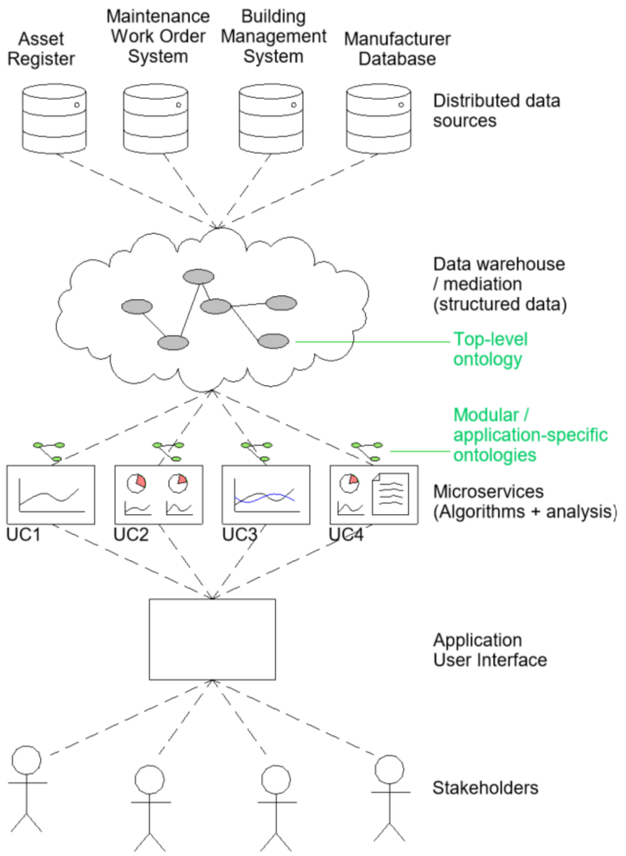

Figure 3: Concept sketch of the proposed system architecture with top-level and modular ontologies identified.

- ***Intended End-Users:*** Asset managers and owners seeking insight on decisions relating to an individual asset or a broader portfolio perspective, and to support performance contract administration. Designers comparing alternative decisions related to building, refurbishment, or maintenance projects. Regulators seeking to audit asset performance in accordance with reporting frameworks.

With the objective of supporting a variety of stakeholders, the proposed system should be ***accessible over the web*** and have an intuitive interface and functionality. Information to support LCSA is typically distributed across multiple, often unintegrated, IT systems, and is a well-established barrier to wider use. Future AM systems should therefore ***integrate information*** using standardised terminology and formalise domain knowledge through logic. Because of the wide variety of contexts to conduct LCC analysis, future systems require the flexibility to ***aggregate information*** consistently, so that assets can be looked at individually or on an aggregated basis across a portfolio, the SLiCE data model (Röck et al., 2024) providing a solid foundation for this. Again, given the wide variety of use cases, a major frustration for practitioners in the current IT landscape is being over-constrained by software. Therefore future AM systems must maintain the ***extensibility to add cost/resource items*** while maintaining a consistent top-down approach based on agreed taxonomies and classification systems. Needless to say, the systems must enable a user to ***conduct life cycle analysis*** based on standardised methodologies, namely ISO 15686-5 (International Organization for Standardization, 2017). A variety a ***'views' of the analysis*** should be possible to visualise including the temporal nature (discount to present value, future value, payback period), and visual nature (graphs, tabular). Due to the data-intensive nature of LCSA activities, an important consideration is validation and trust around the input data. Therefore, future systems need to ***demonstrate data quality*** in terms of provenance and completeness, the Shapes Constraint Language (SHACL) (W3C, 2017) providing a promising technical direction in this regard.

Functional requirements

This sub-section contains excerpts from the Ontology Requirements Specification Document (ORSD). The LOT methodology allows for the use of various requirements gathering approaches. Both Tabular and Competency Question (CQ)-based methods are use in this study. Tabular information includes a specification of Concepts, Relations and Attributes to be encoded in the semantics and logic of the ontology, as well as typical data types, units of measurement and cardinality. An excerpt is shown in Figure 4, denoting between top-level and application-specific aspects.

Since the concept has yet to be expressed in a formal ontology language, we provide informal CQs the proposed system would be expected to answer. CQs support validation during the encoding and testing activities. This list progresses from returning simple attribute values using the top-level ontology to retrieve distributed data, to increasingly complex queries requiring application-specific analytics and modular ontologies.

Top-level:

- CQ1 - What is the [Lifetime] of Asset with [AssetID]?
- CQ2 - Which Assets [List] have a [ResidualValue] > '0'?
- CQ3 - How many Assets [enumerate] have [Condition] in range[1-3]?
- CQ4 - What is the average [AnnualEnergyCost] of Assets with [AssetType]?

Application specific:

- CQ5 - What is the StudyPeriod for the AnalysisEvent [Scenario1]? ***Use Case 1***
- CQ6 - What is the [LifeCycleCost] for SUM[Assets IN AssetResister]? ***Use Case 1***
- CQ7 - What is the percentage breakdown between LifeCyclePhases for Asset [AssetID]? ***Use Case 1***
- CQ8 - Which is the most expensive year given [AnalysisEvent] and which are the Assets being renovated or replaced in that year? ***Use Case 1***
- CQ9 - Which Asset replacement option [list] has the lowest LifeCycleCost over StudyPeriod? ***Use Case 2***

Concepts

Concept	Description
Asset	A very general description of any object (example AHU), or collection of objects (building). Core concept in the ontology.
Cost	Top-level concept, subclasses include various costs (InitialCost, EnergyCost, ResidualCost)
StudyPeriod	Defines the scope of analysis in time
EconomicFactor	Top-level concept, subclasses include Discount and Inflation rates
AnalysisEvent	Specifies a particuar analysis activity

Relations

Concept	Relation	Target	Max cardinality
Asset	hasCost	Cost	1:n
Asset	hasLifetime	Lifetime	1
Asset	hasInstallationDate	InstallationDate	1
Asset	hasCondition	Condition	1
Asset	hasEnergyUse	EnergyUse	1
AnalysisEvent	hasStudyPeriod	StudyPeriod	1
AnalysisEvent	hasEconomicFactor	DiscountRate	1
AnalysisEvent	includesAsset	Asset	1:n

Application specific concepts

Attributes

Concept	Attribute	Description	Value type expected	Max cardinality	Unit
Asset	AssetID	Unique Identifier	String	1	description
Asset	AssetType	Type according to classification system	String	1	description
Asset	InstallationDate	Date of installation	Datetime	1	Datetime
Asset	InitialCost	Capital cost	Float	1	Monetary
Asset	Lifetime	Duration of usable life before requiring decommission/replacement	Int.	1	Years
Asset	ReplacementCost	Future cost of replacement (like for like)	Float	1	Monetary
Asset	RenovationCost	Cost of renovation to prolong lifetime	Float	1	Monetary
Asset	RenovationFrequencey	Number of years before renovation needed to prolong usable life	Int.	1	Years
Asset	AnnualEnergyCost	Cost of energy required to operate the asset	Float	1	Monetary
Asset	AnnualMaintenanceCost	Cost of regular maintenance operate the asset	Float	1	Monetary
Asset	ResidualValue	Positive value of asset at end of usable life (scrappage, upcycling, recycle parts)	Float	1	Monetary
Asset	Condition	Licart rating of an assets operating / quality condition (organisation spepcific, surveyed)	Int.	1	Assessed rating
Asset	AnnualEnergyUse	Sum of energy used over one year	Float	dynamic	kWh
EconomicFactor	InflationRate	Rate of annual inflation	Float	1	%
EconomicFactor	DiscountRate	Rate of discounting future value to present value	Float	1	%

Figure 4: Tabular requirements for modelling financial life cycle cost analysis, gathered per the LOT methodology. Denotes between top-level concepts and those more appropriately stored within modular application ontologies.

- CQ10 - What is the StudyPeriod which makes Option1 outweigh Option2 as the cheaper LifeCycleCost (payback period)? ***Use Case 2***
- CQ11 - What is the percentage reduction in [LifeCycleCost] over [StudyPeriod] for Asset [List] between Date1 and Date2? ***Use Case 3***
- CQ12 - What is Level(s) Indicator [6.1] for [Asset] over [StudyPeriod]? ***Use Case 4*** *- financial life cycle cost according to Level(s)*
- CQ13 - Which Level(s) Indicators [List] have value 'Null'? ***Use Case 4***

Ontology conceptualisation

A conceptualisation activity is carried out based on the above requirements. Concepts are arranged using a diagramming tool. Due to the visual nature, this activity is suitable for collaboration with experts who may not otherwise be familiar with ontology languages. In this case, input was sought from a number of AM and ontology experts via supplementary interviews, who gave input on the domain logic and hierarchical arrangement of concepts. The result of this step is an initial ontology concept diagram (Figure 5).

Potential for reuse and alignment

The LOT authors recommend carrying out an analysis of potential ontology reuse and alignment only after the conceptualisation stage. Table 1 details the considerations in this study for reuse and alignment with existing related ontologies. Based on this assessment it is determined that the RealEstateCore (REC) ontology is most promising for alignment or extension due to the many overlapping concepts, significant existing user-base and the community's active participation in alignment activities. As an exploratory step in this direction, Figure 6 identifies overlapping concepts in the REC ontology. The conclusion here is that our lifecycle information management ontology concept could potentially be achieved with a relatively light extension of the REC ontology. Further investigation will be required, however, to determine the practicality of this proposal.

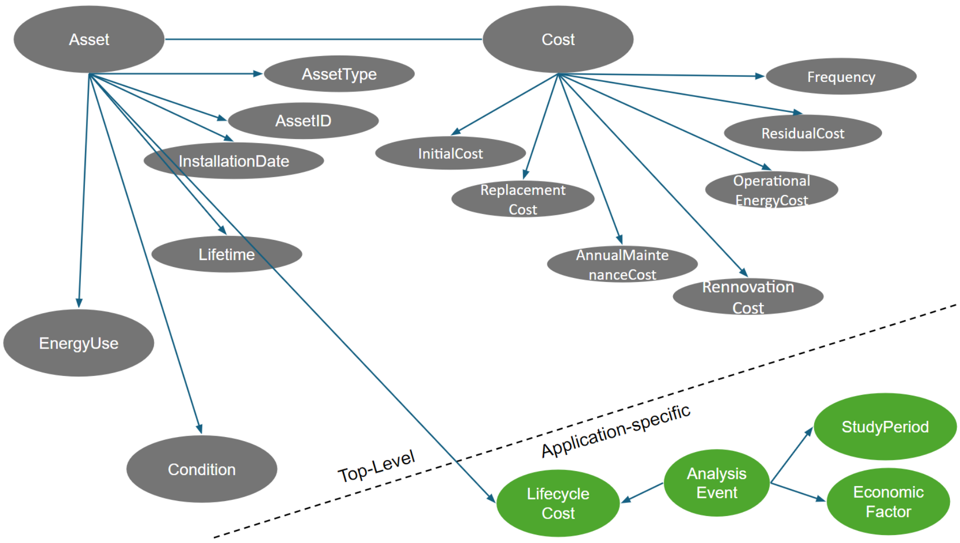

Figure 5: Initial AM Ontology concept denoting top-level and application-specific classes.

Table 1: Existing ontology reuse/extension considerations

Related ontology	Author	Suitable Concepts	Existing user base	Alignment activities	Generality
REC	(Hammar et al., 2019)	Many	Significant	Active	General
SLiCE	(Röck et al., 2024)	Some	Minimal	Active	General
FDM	(Xie et al., 2022)	Some	Unknown	Active	General
BONSAI	(Ghose et al., 2022)	Some	Unknown	Unknown	Macro-specific
LCCA	(Gao et al., 2020)	Some	Unknown	Unknown	Appl.-specific
AMO	(Katsumi et al., 2022)	Few	Under development	Unknown	case-specific

Discussion

The portrayal of the changing regulatory landscape in the built environment at the outset of this paper underscores the growing emphasis on sustainability and resource efficiency. As policy transitions towards mandatory sustainability reporting, the need for robust IT systems which are fit for purpose, becomes paramount. Life cycle analysis has emerged as a means to counteract the phenomenon of short-term-ism in decision-making by viewing impacts of decision over longer time periods. Our previous research portrays the current IT landscape as not fit for purpose to meet future information requirements, and advocates reconfiguration of future systems.

Illustrating our vision for this new software landscape, we outline a scenario whereby various stakeholders access a shared knowledge base, structured semantically around commonly agreed concepts over the web. Through specialised, modular applications, stakeholders leverage this shared knowledge base to suit their specific analytical needs. Following the LOT ontology development methodology, we describe the activities in developing an initial concept, focusing on fundamental AM use cases which serve a variety of key AM stakeholders. This involves defining the scope and use cases, gathering requirements via background research, conceptualising and verifying the ontology logic with experts, and exploring potential alignment with existing efforts. We present excerpts from the Ontology Requirements Specification Document (ORSD), including natural language Competency Questions (CQs) and tabular information, which lay the groundwork for encoding domain knowledge in a formal ontology language. The outcome is an initial conceptualisation of the AM ontology, with a recommendation for alignment with the RealEstateCore ontology, a data model which already describes multiple concepts useful for AM stakeholders and our use cases. Alignment with the RealEstate-

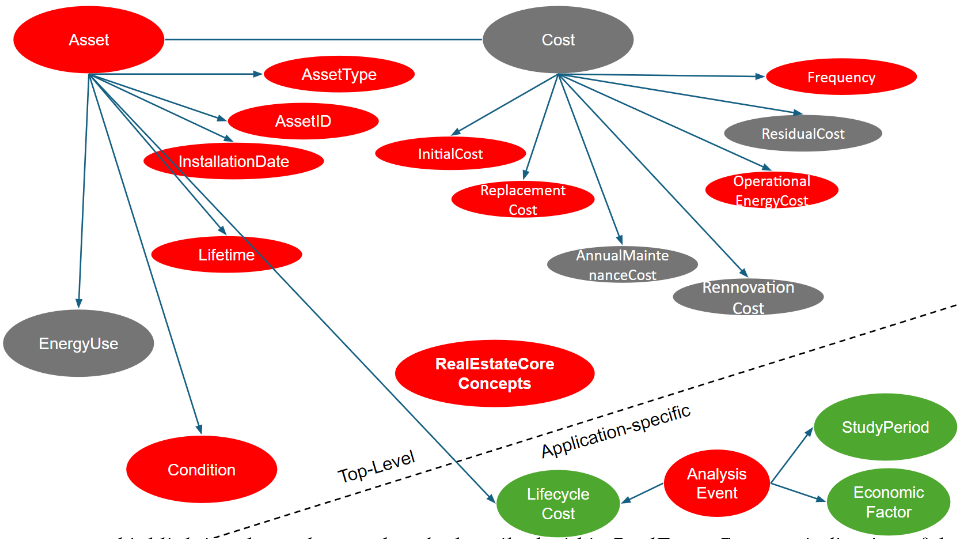

Figure 6: Ontology concept highlighting those classes already described within RealEstateCore, an indication of the extent to which REC would require extension to accommodate our research objectives.

Core ontology presents a strategic opportunity for uptake, given its existing user base and openness to alignment efforts with other ontology communities. Looking ahead, our vision for the future IT landscape aligns with the efforts of researchers in the built environment informatics domain, in particularly the activities of the Linked Building Data community (W3C, 2022).

Though this study is based upon extensive prior practitioner-based research in the AM and LCSA fields, we stop short at validating the ontology through encoding and testing in real-world scenarios, activities which remain as future work. Furthermore, though the selected use cases serve a broad selection of key stakeholders, the outcomes are nonetheless limited to describing those few applications. There are, of course, a vast range of potential uses for such a knowledge base, which is entirely the objective of the extensible and modular approach described; but with the rapidly approaching requirements of the CSRD and other sustainability reporting requirements, if we are to ensure equitable participation, it is of utmost importance to support the domain in managing their asset information particularly small-medium enterprises. Our next endeavors will focus on expanding the ontology concept to cover additional use cases and we will progress through the subsequent stages of the LOT development methodology activities to encode and validate the concept, ensuring its applicability and effectiveness in real-world scenarios.

Conclusions

This paper advocates a paradigm shift in IT systems within the built environment to align with environmental sustainability policy ambition. Proposing a web-enabled technology stack and leveraging the Linked Open Terms (LOT) methodology, we illustrate a asset management ontology landscape fit for purpose, allowing for modularity of specialised stakeholder applications ingesting shared information from a common knowledge base. With a focus on supporting fundamental Life Cycle Sustainability Assessment use cases, our research lays the groundwork for technical ontology development by gathering domain insight, outlining functional requirements and conceptualising the modular ontology landcsape. By reflecting on related research efforts, we highlight the potential for aligning with or extending existing standards such as RealEstateCore and SLiCE data models. This work contributes to fostering consensus within the domain, offering a roadmap for future research and development in enhancing asset lifecycle information management and decision-making processes.

Data Sensing and Acquisition

IDENTIFICATION OF COMPOSITE SENSOR FAULTS IN STRUCTURAL HEALTH MONITORING SYSTEMS USING LONG SHORT-TERM MEMORY NETWORKS

Thamer Al-Zuriqat, Heba Al-Nasser, Kosmas Dragos, Chillón Geck, and Kay Smarsly
Hamburg University of Technology, Hamburg, Germany

Abstract

Fault identification (FI) is an integral part of sensor fault diagnosis in structural health monitoring (SHM) systems. However, current FI approaches often overlook composite sensor faults, i.e. different sensor fault types occurring simultaneously within an individual sensor. As a result, actual fault occurrences in real-world SHM systems may be underestimated. This paper introduces an FI approach utilizing long short-term memory networks, addressing composite faults. The FI approach is validated using sensor data recorded by a real-world SHM system. The results demonstrate the capability of the FI approach to identify composite sensor faults, thus enhancing the reliability and accuracy of fault diagnosis.

Introduction

Structural health monitoring (SHM) is a non-destructive evaluation technique employing data recorded by sensors ("sensor data") to assess structural conditions (Law et al., 2014). SHM aims to improve safety and cost efficiency in structural maintenance through filling gaps of periodic visual inspections (Cawley, 2018). Hardware or software errors, exposure to harsh environmental conditions, degradation, and signal interferences may lead to malfunctions of sensors ("faulty sensors") in SHM systems (Zhang et al., 2018). Consequently, faulty sensors may compromise the outcomes of SHM systems (Steiner et al., 2019).

In SHM systems, sensor fault types include bias, drift, gain, precision degradation, complete failure (constant or with noise), and outliers (Kullaa et al., 2013). Fault diagnosis approaches for SHM systems have been proposed based on either physical or analytical redundancy (Frank, 1990). Physical redundancy entails installing additional, i.e. "redundant", sensors and detecting faults based on sensor data comparisons. However, the high cost, power consumption, and maintenance associated with physical redundancy have been the primary motivation for developing analytical redundancy approaches (Smarsly & Petryna, 2014). In general, analytical redundancy employs mathematical models to characterize a system, leveraging the inherent redundancy present in the sensor data (Al-Zuriqat et al., 2023). Fault diagnosis using analytical redundancy comprises four steps (Patton, 1990):

- Fault detection
- Fault isolation
- Fault identification
- Fault accommodation

In the fault detection step, residuals between sensor data and corresponding "virtual outputs", derived from mathematical models, are evaluated using threshold logic or hypothesis testing (Isermann & Balle, 1997). In case faults are detected, fault isolation involves determining the locations of the faulty sensors. To gain insights into the underlying causes of sensor faults and define strategies for compensating for errors induced by sensor faults, the type or nature of the faults are determined in the fault identification (FI) step. Finally, in the fault accommodation step, data recorded by the faulty sensor is reconstructed using virtual outputs of the mathematical models.

Existing fault diagnosis approaches have mainly focused on detecting, isolating, and accommodating sensor faults. Rao et al. (2007) has presented a concept, originally proposed by Kramer (1992), introducing a null-subspace-based approach for sensor fault detection and isolation, combined with autoassociative neural networks for fault accommodation. Smarsly & Law (2014) have proposed a decentralized fault detection and isolation approach in wireless SHM systems employing artificial neural networks. The approach has been extended from the time domain to the frequency domain and has also accounted for the presence of structural damage (Dragos & Smarsly, 2016). Al-Zuriqat et al. (2023) have introduced an adaptive sensor fault detection, isolation, and accommodation approach for SHM systems using feedforward artificial neural networks with backpropagation, considering single sensor faults occurring simultaneously in individual sensors. Liu et al. (2022) have used stacked gated recurrent unit neural networks to detect, isolate and accommodate sensor faults, and global-local logic to differentiate sensor faults from structural damage.

Among fault diagnosis approaches that include FI, Fritz et al. (2022) have proposed an analytical-redundancy approach, which integrates feedforward artificial neural networks and convolutional neural networks to detect, isolate, identify, and accommodate sensor faults. Additionally, other approaches, based on generalized likelihood ratio (Li et al., 2019), on generalized quasi-natural analogy test principle (Yan et al., 2020), and on set theory and support vector machine (Yu et al., 2014), have also addressed the FI step. However, in the aforementioned studies, only single sensor faults have been considered, i.e. one sensor fault type within each individual sensor. Moreover, not all sensor fault types have been addressed. For example, outliers (Fritz et al. 2022; Li et al., 2019), drift, precision degradation, and complete failure (Yan et al., 2020) have not been included.

Sensors in SHM systems may experience combinations of faults, i.e. faults of different types occurring simultaneously within an individual sensor (hereinafter termed "composite sensor faults"). The plausibility of composite sensor faults occurrence in SHM systems has been corroborated in Li et al. (2023), in which composite sensor faults have been observed during experimentation, specifically gain and drift in one sensor. Composite sensor faults have been investigated in other disciplines for more than two decades, for example, in boiler processes using structured residuals with maximized sensitivity (Qin & Li, 1999), in wastewater treatment plants using Fisher discriminant analysis (Luca et al., 2023), and in lithium-ion batteries using a two-layer identification algorithm (Shen et al., 2024).

Despite the importance of FI in gaining insights into underlying causes of sensor faults within SHM systems, current FI approaches take into consideration single sensor faults, often failing to account for composite sensor faults, which may manifest in real-world SHM systems (Li et al., 2023). Moreover, current FI approaches rely on recognizing unique patterns in sensor data to identify different sensor fault types (Peralta et al., 2022). Nonetheless, composite sensor faults may generate distinct patterns that may be hard to recognize for current FI approaches. In this paper, an approach towards identification of composite sensor faults (ICSF) is proposed. Sensor data with artificially injected composite sensor faults is used to train long short-term memory (LSTM) classification networks, addressing composite sensor faults.

The remainder of the paper is organized as follows: First, composite sensor faults in SHM systems are elucidated. Then, a description of the ICSF approach is introduced. Next, the implementation and validation of the ICSF approach are presented, and the results are discussed. Finally, the paper ends with a summary and conclusions, and an outlook on future research is provided.

Composite sensor faults

Sensor fault types manifest into errors, which have distinct footprints on sensor data. For example, a bias is represented by a constant deviation of the sensor data from the values that should be measured ("actual values", e.g. structural responses or environmental parameters). A drift is characterized by the gradual deviation of sensor data from the actual values over time. A gain occurs when sensor data is systematically scaled by a constant value. Precision degradation is caused by the contamination of sensor data with noise. A complete failure is observed as sensor data consisting of a constant value ("complete failure constant") or noise ("complete failure with noise"), regardless of changes occurring in the actual values. Finally, an outlier manifests as a discontinuous observation in the sensor data that deviates from the actual values at isolated time instances.

The aforementioned sensor fault types are usually addressed as single sensor faults, occurring in individual sensors. However, as mentioned previously, sensors in real-world SHM systems may experience composite sensor faults, an example of which, consisting of drift and an outlier, is illustrated in Figure 1. As a result, full fault identification needs to address both *single sensor faults* and *composite sensor faults*. The description of the ICSF approach, including two phases, each comprising several steps, are presented in the following section.

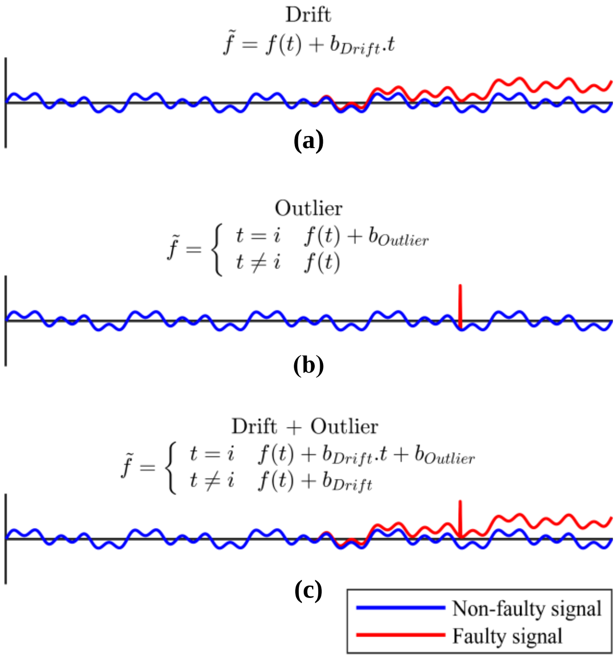

Figure 1: Illustration of a composite sensor fault: (a) a single sensor fault with drift, (b) a single sensor fault with an outlier, and (c) a composite sensor fault consisting of drift and an outlier

Description of the ICSF approach

In this section, the ICSF approach is presented, comprising two phases, (i) preparing the training dataset, and (ii) developing the classification models. A flowchart describing the workflow of the ICSF approach is shown in Figure 2.

Phase 1: Preparing the training dataset

1. Sensor data is recorded by SHM systems within the so-called "data collection period". The total number of data points p recorded by each sensor in the data collection period is representative of the normal operation of the structure.
2. A correlation analysis is conducted on the sensor data to unveil the number of correlated sensors k within a SHM system. Since the classification models are based on mapping sequences of sensor data, correlation between sensors is a prerequisite. Each sensor in the set of correlated sensors is denoted with i (i = 1, …, k). Data recorded by all correlated sensors $f_{1 \to k}$ is stored in matrix **A**. As result, matrix **A** has a length equal to the number of data points p, and a width equal to the number of correlated sensors k, as shown in Equation 1.

$$\mathbf{A}_{p \times k} = \begin{bmatrix} f_{1,1} & f_{1,2} & \cdots & f_{1,k} \\ f_{2,1} & f_{2,2} & \cdots & f_{2,k} \\ \vdots & \vdots & \ddots & \vdots \\ f_{p,1} & f_{p,2} & \cdots & f_{p,k} \end{bmatrix} \quad (1)$$

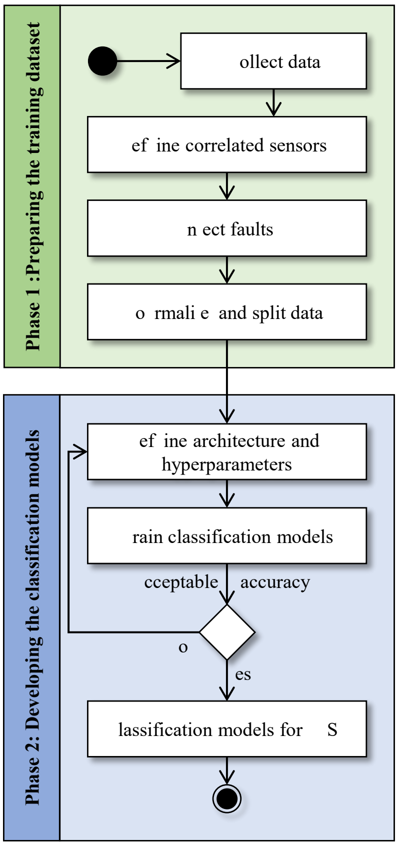

Figure 2: Flowchart of the ICSF approach

3. A total of k input and output datasets are created to train classification models in a later step. The sensor data in matrix **A** are copied into input dataset i (i = 1, …, k), and composite sensor faults are artificially injected into the vector $\mathbf{f}_i$, i.e. in sensor data recorded by sensor i. Each fault is injected via a mathematical model, representing the footprint of the fault on the sensor data (e.g. adding a constant value to the sensor data to simulate bias). Injected sensor fault types are stored in the classification output dataset i. As a result, the input dataset i contains clean data from sensors (1, 2, …, i–1, i+1, …k), and sensor data from sensor i with composite sensor faults.
4. Data in the input dataset i is normalized using a minimum-maximum normalization method, shown in Equation 2, to avoid overfitting issues while training the classification models. Then, the normalized input dataset i, as well as the output dataset i are split into training dataset (70%), validation dataset (15%), and testing dataset (15%). In Equation 2, x represents an arbitrary measurement in the sensor data, while x_{min} and x_{max} denote the minimum and maximum measurements in the sensor data, respectively. The variable $x_{normalized}$ corresponds to the normalized value. Both normalization parameters x_{min} and x_{max} used for the input dataset i are saved to be applied to new sensor data that is fed to the classification model M_i after training.

$$x_{normalized} = \frac{x - x_{min}}{x_{max} - x_{min}} \qquad (2)$$

Phase 2: Developing the classification models

1. The initial architecture of the LSTM classification network is defined. The LSTM classification network has an input layer, hidden layers, and an output layer. In Figure 3, the general architecture of the LSTM classification network is illustrated. The input layer is a sequence input layer with a length equal to the number of correlated sensors k. The hidden layers include successions of LSTM layers and "dropout" layers. In each LSTM layer, memory cells and a set of gates regulate the flow of data. This architecture enables LSTM layers to capture and retain long-term dependencies in sequential data, making them particularly effective for tasks such as sensor data analysis. In each dropout layer, a probability of dropout is defined representing the likelihood (set between 0 and 1) of randomly neglecting measurements passed through the LSTM layer as means of preventing overfitting. The number of LSTM layers as well as the number of dropout layers may vary based on the model accuracy, which is determined in a later step. The output layers contain a fully-connected layer, a Softmax layer, and a classification layer. The fully-connected layer connects every neuron of the last hidden layer to the neurons of the output layer, representing the number of classes in the classification problem. The Softmax layer is used

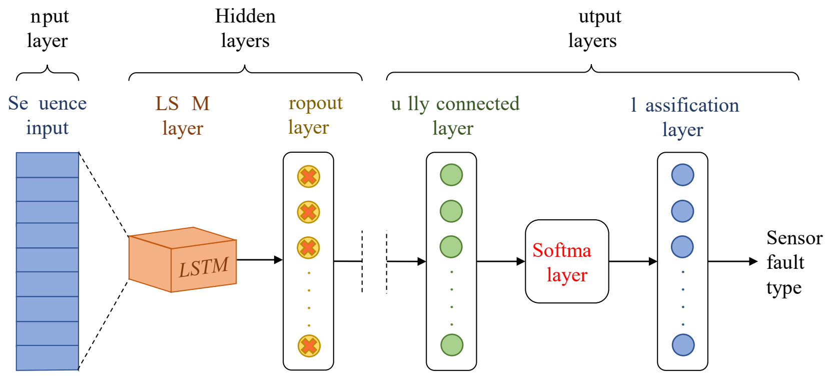

Figure 3: General architecture of the LSTM classification network

between the fully connected layer and the classification layer to convert raw logits into probability distributions, facilitating interpretability, backpropagation, and optimal training. Finally, the classification layer contains all classes of the classification problem, more specifically, the number of sensor fault types c to be included in the FI step. The number of sensor faults c, is calculated using Equation 3, and depends on: (i) the number of single sensor faults m included in each composite sensor fault, and (ii) the total number of single sensor faults n included in all composite sensor faults.

$$c\ (n, m) = \frac{n!}{m!(n-m)} \quad (3)$$

2. One classification model M_i for each correlated sensor i (i = 1, ..., k) is created by training an LSTM using the training dataset i. During training, the training dataset i is fed sequentially (in "batches") to the LSTM classification network, i.e. each batch of the normalized input dataset is fed to the input layer and the corresponding classes of the output dataset are fed to the output layer. The training consists of updating weighted connections between neurons, until the probabilities of the Softmax layer reach a predefined level of accuracy. Thereupon, the classification model M_i is created, capable of recognizing patterns and features in the input dataset i and classifying the sensor data into the corresponding composite sensor fault type. The validation dataset is used to fine-tune the hyperparameters, and prevent overfitting during training.
3. Upon completing training and validating, the accuracy of model M_i is obtained using the testing dataset. For model M_i to be accepted, the classification accuracy must lie above a FI threshold γ. The FI threshold γ is derived following the same rationale as the fault detection threshold γ in previous related research (Al-Zuriqat et al., 2023). Equation 4 introduces the formula to calculate the accuracy (Acc) of the classification model M_i.

$$Acc = \frac{Number\ of\ correct\ preditions}{Total\ number\ of\ preditions} \quad (4)$$

4. Finally, if the accuracy of model M_i is satisfactory, the model is saved to identify faults of sensor i (i = 1, …, k). However, if the accuracy of model M_i is not satisfactory, a different architecture of the LSTM classification network is defined and a new model M_i is trained (back to step 1 of phase 2).

The implementation and validation of the ICSF approach using sensor data from a real-world SHM system installed on a pedestrian bridge is presented in the next section.

Implementation and validation of the ICSF approach

This section describes the implementation and validation of the ICSF approach. To implement the ICSF approach, the programming language MATLAB is utilized to analyze the sensor data, inject faults, and train the classification models. The validation test is carried out using sensor data (acceleration measurements) from a real-world SHM system installed on a pedestrian bridge. First, the pedestrian bridge and the SHM system are presented. Then, the ICSF approach is applied using the acceleration measurements recorded by the real-world SHM system.

Description of the pedestrian bridge and the SHM system

The pedestrian bridge, located in Evosmos, Thessaloniki, Greece, has been a subject of research since the construction in 2016. (Dragos et al., 2020; Smarsly et al., 2022a; and Smarsly et al., 2022b). The pedestrian bridge, is a composite concrete-steel structure, in which a steel structure supports a reinforced-concrete deck. The dimensions of the reinforced-concrete deck are 35.00 m (length) and 4.60 m (width).

Figure 4 illustrates the top view of the pedestrian bridge and the locations of the accelerometers used in the validation test. The SHM system comprises four accelerometers (i.e. S_1, S_2, S_3, and S_4), which have been previously tested and found to be free of faults. The accelerometers are equally distributed along the central axis spanning the length of the bridge, spaced seven meters apart from each other.

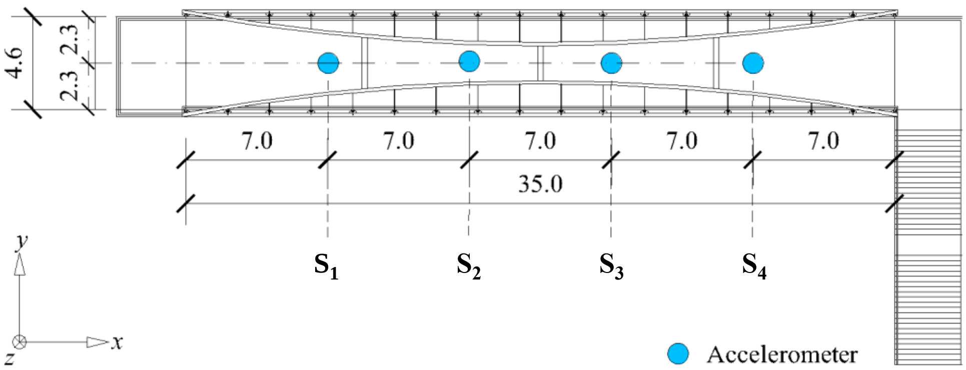

Figure 4: Top view of the pedestrian bridge with the locations of the accelerometers (dimensions are given in meters)

Description of the validation test

For preparing the training dataset (phase 1), acceleration measurements are recorded by the four accelerometers (S_1, S_2, S_3, and S_4) over data collection period of 90 minutes at a sampling rate of 128 Hz. The total number of data points $p = 692{,}628$ is recorded by each accelerometer.

Next, correlations within the acceleration measurements are investigated via a correlation analysis. A strong correlation has been exposed by the Pearson correlation coefficient among all four accelerometers, i.e. $k = 4$. Notably, the lowest correlation coefficient 0.937 has been observed between sensors S_1 and S_4. Then, the acceleration measurements, recorded by all four correlated accelerometers $f_{1 \rightarrow k = 4}$, are stored in matrix $\mathbf{A}_{692628 \times 4}$.

To determine the sensor fault types to be included in the validation test, as well as the size of the classification layer in a later step, a total of five single faults ($n = 5$) are considered, i.e. bias, drift, gain, precision degradation and outliers. Complete failure, either constant or with noise, entails sensors essentially ceasing to operate and can, therefore, hardly be combined with other single sensor faults into composite sensor faults. Combinations of two single faults in the same sensor ($m = 2$) are considered, e.g. drift and outlier at the same time within an individual sensor. As a result, using Equation 3, the total number of composite sensor faults is $c\,(n, m) = 10$. Table 1 provides an overview of the composite sensor faults considered in the validation test.

Table 1: Sensor fault types considered in the validation test

No.	Composite sensor fault
1	Bias + Drift
2	Bias + Gain
3	Bias + Precision degradation
4	Bias + Outliers
5	Drift + Gain
6	Drift + Precision degradation
7	Drift + Outliers
8	Gain + Precision degradation
9	Gain + Outliers
10	Precision degradation + Outliers

Acceleration measurements stored in matrix $\mathbf{A}_{692628 \times 4}$ are copied into four input datasets. Each input dataset is divided equally into 10 subsets, for which each sensor fault type shown in Table 1 is artificially injected. The classes of the composite sensor faults injected into the input dataset i ($i = 1, \ldots, 4$) is stored in the output dataset i ($i = 1, \ldots, 4$).

Next, acceleration measurements, stored in the input dataset i, are normalized using the minimum-maximum normalization method shown in Equation 2. The normalized input dataset i is split into 70 % training dataset (484,838 data points), 15 % validation dataset (103,894 data points), and 15 % testing data (103,894 data points). Both normalization parameters x_{min} and x_{max} used for the input dataset i during training are saved, to be applied to new sensor data that is fed to the classification model M_i after training.

The initial architecture for the LSTM classification network is defined, with the input layer consisting in a sequence input layer with length $k = 4$. The output layer consists of a fully-connected layer, a Softmax layer, and a classification layer with 10 classes, where each class present a composite sensor fault from Table 1. Three hidden layers are defined, each comprising a LSTM layer followed by a dropout layer. To avoid overfitting during training, the probability of all dropout layers has been set to 20 %.

A total of four classification models, equal to the number of the correlated sensors ($k = 4$), are created by training an equal number of LSTM classification networks. Each model M_i classifies sensor fault types of sensor i, using acceleration measurements from the four correlated sensors of the SHM system as input data. A total training time of 69 minutes for each LSTM classification model is recorded.

Based on Equation 4, the accuracy of the models is evaluated using the testing dataset (103,894 data points). Using a FI threshold $\gamma = 0.85$, a model with an accuracy above 85 % is considered acceptable (Al-Zuriqat et al., 2023). The lowest model accuracy has been observed in model M_2, with an accuracy of 90.3 %.

Finally, the fourth step involves saving all trained classification models M_1, M_2, M_3, and M_4 to identify sensor fault types for sensor S_1, S_2, S_3, and S_4, respectively. The trained classification models are tested using acceleration measurements newly recorded by the SHM system, as presented and discussed in the following section.

Results and discussion

This section presents and discusses the results of applying the classification models (M_1, M_2, M_3, and M_4), obtained by the ICSF approach, to newly recorded acceleration measurements. The acceleration measurements used in the validation test have been recorded by the real-world SHM system and correspond to a data collection period of 30 minutes with a sampling rate of 128 Hz. The total number of data points recorded by each of the accelerometers is $p = 230{,}876$ data points. Subsequently, all composite sensor faults introduced in Table 1 have been randomly injected into the newly recorded acceleration measurements. The purpose of the injected faults here is to provide a labeled dataset, which is used to evaluate the accuracy of the classification models. Table 2 presents the results of testing the classification models. To determine the accuracy of the classification models, the number of sensor faults identified is compared to the number of sensor faults injected in the testing dataset.

Table 2: Fault identification results of artificially injected sensor fault types including composite faults

Fault type	Sensor	Injected faults	Correctly identified faults	*Acc*
Bias + Drift	S_4	13,607	13,600	99.9 %
Bias + Gain	S_1	13,522	13,411	99.1 %
Bias + Precision degradation	S_2	13,720	13,632	99.3 %
Bias + Outliers	S_3	5,378	4692	87.2 %
Drift + Gain	S_4	13,627	12859	94.3 %
Drift + Precision degradation	S_1	13,390	12,944	96.6 %
Drift + Outliers	S_2	5,461	261	4.7 %
Gain + Precision degradation	S_3	13,638	13,373	98.0 %
Gain + Outliers	S_4	5,556	4,871	87.6 %
Precision degradation + Outliers	S_1	5,398	4,126	76.4 %
Total	**-**	**103,297**	**93,769**	**90.7 %**

As presented in Table 2, the FI capabilities of models M_1, M_2, M_3, and M_4 have been demonstrated using the newly recorded acceleration measurements with artificially injected faults. Out of 103,279 faults injected into the newly recorded acceleration measurements, 93,769 sensor fault types have been correctly identified, representing a total accuracy rate of 90.7 %.

Upon delving deeper into the results of the identification of composite sensor faults, it is noticeable that the classification model achieved the highest accuracy in identifying the composite sensor fault "Bias + Drift" with an accuracy rate of 99.9%. Conversely, a considerably low accuracy rate was observed in the identification of the composite sensor fault "Drift + Outliers" at 4.8%. The low accuracy of identifying the composite fault type "Drift + Outliers" may be attributed to the subtle patterns of outliers, as they correspond to point singularities in a continuous signal, which may be hard to be identified as features by the LSTM classification network.

Summary and conclusions

Fault diagnosis using analytical redundancy, building on mathematical models, has been gaining increasing interest in SHM, owing to the low cost when avoiding redundant sensors, as compared to traditional physical redundancy approaches. Fault diagnosis encompasses fault detection, isolation, identification, and accommodation. Despite the importance of FI in gaining insights into underlying causes of sensor faults within SHM systems, current FI approaches often fail to account for composite sensor faults, which may manifest in real-world SHM systems.

This paper has presented an approach towards identification of composite sensor faults (ICSF). Sensor data with artificially injected composite sensor faults has been used to train LSTM classification networks, addressing composite sensor faults. The ICSF approach has been implemented using the programing language MATLAB, and validated using acceleration measurements recorded by a real-world SHM system. From the results, it is concluded that the ISCF approach has been proven capable of identifying composite sensor faults, thus enhancing the reliability and accuracy of fault diagnosis in SHM systems.

Future work may involve coupling the ICSF approach with other existing fault detection, isolation, and accommodation approaches to establish a comprehensive fault diagnosis concept. Furthermore, the ICSF approach may be embedded into wireless sensor nodes to identify sensor faults on board the sensor nodes within real-world decentralized SHM systems.

ESTIMATE ROAD ROUGHNESS USING SAMRTPHONE RESPONSE DATA - A SEMI-SUPERVISED LEARNING APPROACH

Qiqin Yu[1], Ye Sang[1], Yihai Fang[1], Viet Vo[2], and Richard Wix[3]

[1]Department of Civil Engineering, Monash University, Melbourne, Australia

Abstract

The smartphone-collected vehicle response data is being used to estimate the International Roughness Index (IRI). Among the existing smartphone-based methods, the data-driven approach, which involves training a machine learning model, is drawing more attention. However, surveying the IRI using conventional methods is expensive and there is limited labelled response data. In contrast, there exists a wealth of unlabelled response data from road users. This scenario presents opportunities for exploring semi-supervised learning (SSL) algorithms, which have been insufficiently researched in this domain. This study addresses this gap by applying an SSL framework to refine an IRI estimation model. Our results show that the SSL-trained model achieves a lower RMSE than the fully supervised trained model.

Introduction

Pavement deteriorates under the effects of traffic loading and environmental conditions, resulting in defects such as potholes and cracks. These failures affect ride quality and increase the likelihood of vehicle damage and safety risks. A road roughness index indicates the condition of the road, and the most prevalently used one is the International Roughness Index (IRI) (Yu et al., 2022). Conventional roughness index estimation (RIE) systems are labour-intensive, and require a complex set-up Qiqin Yu and Wix (2023). As a result, these systems are limited in surveying frequency and spatial coverage. Studies have proposed utilising a crowdsourcing-based approach to tackle these issues, since the proliferation of smartphones presents an opportunity to leverage data from road users (Staniek, 2021). The embedded sensors, such as the accelerometer and gyroscope, could be exploited to characterise road pavement based on the traversing vehicles' responses. Such a collaborative assessment approach could potentially supplement conventional instruments by locating distressed road segments more responsively and cost-effectively.

Existing studies have focused on increasing the accuracy of smartphone-based systems by applying statistical-based methods, vehicle mechanistic model-considered and machine learning methods (Yu et al., 2022). However, a dominant difference between the smartphone-based method and the conventional approaches is the amount of data generated. The data generated from the smartphone-based approach is thousands of folds to that of the conventional approaches. Many vehicles are driving on relatively fixed routes (e.g., from home to work), and the response data from these vehicles could effectively indicate the pavement roughness condition. In practice, collecting data in road segments labelled by ground-truth IRI is expensive and likely unavailable in remote regions. As a result, only a small amount of smartphone response data could be mapped with the ground-truth IRI. Meanwhile, there is a large amount of useful response data driving on road networks whose IRI is unknown and such data becomes unlabelled. It is believed that such response data should also be exploited to contribute to the IRI estimation model. Essentially, only a small percentage of samples are labelled while the majority remains unlabelled, and this scenario presents opportunities for exploring semi-supervised learning (SSL) algorithms and little research has touched this area. To fill the gap, this study proposes an SSL-based framework for estimating IRI by considering both labelled and unlabelled vehicle response data.

The rest of the paper is organised as follows. The Literature Review section summarises relevant studies in SSL and smartphone-based roughness index estimation (sRIE) methods. Next, the Methodology section elaborates on the proposed framework for IRI estimation using SSL. The Data Collection and Data Pre-processing sections provide information on obtaining and preparing data for training. The Experiment section details the training of the initial IRI-estimation model and the implementation of the SSL technique. Lastly, the Discussion section breaks down the contributions and limitations of this study and sheds light on directions of future research.

Literature review

Semi-supervised learning

As the quantity of available data grows and the hardware computational capabilities grow, deep learning (DL) has been making significant contributions in various applications (Pouyanfar et al., 2018). However, the prerequisite of these encouraging results usually relies on a large amount of labelled data, which is often expensive and difficult to obtain compared with unlabelled data (Ouali et al., 2020). Hence, semi-supervised learning (SSL) was proposed to leverage a volume of unlabelled data to improve the DL model performance based on a small number of labelled data. Specifically, with respect to loss function and model design, the SSL methods could be categorised into 5 groups, deep generative methods, consistency regularization methods, graph-based methods, pseudo-labeling methods, and hybrid methods (Yang et al., 2022). For example, given labelled data, the typical Generative Adversarial Networks (GAN), as described in

Ian et al. (2020), consist of two neural networks, a generator, and a discriminator, and were supposed to generate new samples through adversarial training. As a consistency regularization method, Mean Teacher (Tarvainen and Valpola, 2017) leverages consistency regularization to train the model with both high accuracy and strong robustness by integrating Exponential Moving Average (EMA) during the training step. Meanwhile, the manifold assumption, a fundamental principle in semi-supervised learning (Learning, 2006), has been employed by GoodBadGNN to enhance the model's inference performance (Dai et al., 2017). Pseudo-label claimed a straightforward and effective approach for training a robust deep learning model by initially training it on labelled data and subsequently retraining the model with high-confidence predictions on unlabelled data (Lee et al., 2013). Moreover, since most semi-supervised learning methods rely on unique structure in the domain data, a hybrid method, the VIME (Value Imputation and Mask Estimation) was proposed for tabular data that does not have explicit structure as image data (Yoon et al., 2020). Overall, SSL methods are used to learn the underlying pattern from unlabelled datasets and hence to augment the labelled dataset. Specifically, Consistency regularization methods directly improve the performance and robustness of the DL model by contrasting learning. Pseudo-labeling enhances model performance by initially training on a limited labeled dataset, followed by generating predicted labels with high confidence from an unlabeled dataset, which are subsequently integrated into the training process to retrain the initial deep learning model.

In terms of using semi-supervised learning in data-driven approach, it didn't apply any SSL algorithm to leverage the unlabelled response data to improve the performance of an IRI estimation model. To the author's knowledge, no other studies have applied SSL algorithms in estimating the IRI.

Crowdsourcing-based infrastructure health monitoring

Estimations made by a single smartphone may be inadequate in accuracy and consistency. Crowdsourcing smartphone measurements aim to aggregate measurements from a large number of participants. Big data enables analysis of the impact of practical factors, including speed, vehicle types, smartphone models, and mounting configuration/position, on the response-based IRI estimation method. Li and Goldberg (2018) proposed crowdsourcing systems to evaluate pavement roughness. Recently, Jeong and Jo (2023) implemented a validated IRI-estimation approach using response data collected from 29 vehicles, 8 smartphone models, and 5 mounting types. By considering various practical settings, their study was conducted in a controlled environment and the participants surveyed a single route of 18.2 km.

Methodology

This section provides an overview of the proposed framework for estimating the IRI by incorporating the profiler, sRIE systems and the crowdsourcing participants. The framework contains two modules. The first module features a multilayer perceptron (MLP) model for estimating the IRI, and the second module engages crowdsourcing data collection and leverages an SSL framework to improve the accuracy of the trained model. A schematic

by the profiler are called labelled roads since their
truth IRI is known and the vehicle's response data
routes are labelled data. In contrast, other roads a
unlabelled roads and their vehicle response da
labelled. The SSL makes use of a small amou
belled data with a large amount of unlabelled d
et al., 2021), and increases the accuracy of the MI
developed in Module 1. This study adopts the
framework "VIME (Value Imputation and Mask Estimation)" that employs a data augmentation method, generating augmented samples for each feature set (Yoon et al., 2020). Specifically, unlabelled data are fed into VIME, which learns the underlying patterns within features. To achieve this, the original feature matrix X is shuffled to create a new feature matrix $\hat{X}$. A mask matrix M, with the same dimensions as the feature matrix X, is generated based on the Bernoulli distribution, and its counter-

Data collection

This section details the experiment routes and set-up of the data collection instruments, including the profiler and the smartphone-based response data collection system.

Survey routes

As shown in Figure 3, six routes around the Clayton campus of Monash University, in Melbourne, Australia, were selected. The routes collectively span a total length

Figure 3: Experiment survey routes

Ground-truth IRI survey instrument

The ground-truth IRI was surveyed using an inertial profiler system from the National Transport Research Organisation (NTRO). This instrument was certified in accordance with the Austroads standards on profiler validation (Austroads, 2016). The inertial profiler consists of a laser profilometer and accelerometers. The laser profilometer measures the distance to the road surface while the self-movement of the vehicle body is integrated from the accelerometer measurements. Knowing the initial height of the laser profilometer, the roughness elevation profile can then be calculated. The IRI is then computed by running the Golden-Car simulation on the measured profile. Two repetitive runs were conducted on all routes to obtain robust ground-truth IRI measurements which were sampled at a 10m interval. The distribution of the ground-truth IRI values in five survey routes is illustrated in Figure 3.

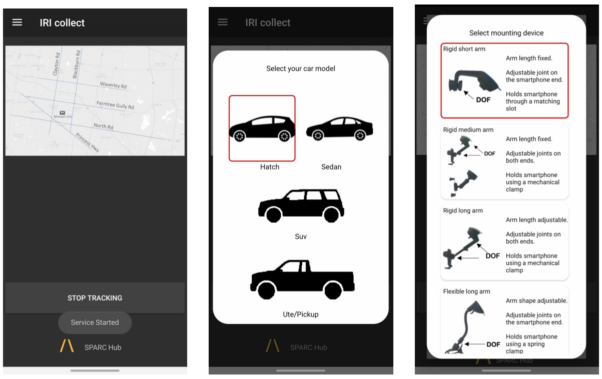
Figure 4: Ground-truth IRI instrument

Table 1: Ground-truth IRI distribution

IRI Band	Quantity	Percentage
0-2	44,665	45.8%
2-4	44,213	45.4%
4-6	6,823	7%
6-8	1,445	1.5%
8-10	216	0.2%
>10	123	<0.1%

Figure 5: Smartphone IMU sensor axial orientations.



(a) Home (b) Vehicle select (c) Mount select

Figure 6: Data collection App user interface.

Smartphone-based response data collection system

The vehicle response data is collected from common passenger car models of different body types. Four smartphones of the same model, each held using a different mount, were deployed to collect the vehicle response data, as demonstrated in Figure 5. The four mountings were different in their arm length and mechanism type and represented the range of commonly available models in the market. Meanwhile, an Android application was developed to collect the smartphone's IMU and GPS data. The collected data includes the timestamp, tri-axial accelerometer, tri-axial gyroscope, rotational sensor, GPS and speed. The App interfaces are shown in Figure 6. The user's vehicle body type and mounting type were also recorded in the App.

Data preprocessing

Data preprocessing contains two tasks, data mapping and data cleaning. Data mapping assigns the smartphone measurements with the ground-truth IRI. Each acceleration measurement now has its own latitude and longitude records. Meanwhile, the latitude and longitude of the start and end points of each 10m ground-truth IRI segment are known. By selecting the smartphone data points that are spatially closest to the reference start and end points of each segment and knowing their timestamp, the time window that corresponds to the reference segment could be determined. The mapping was completed by assigning the smartphone data points in this time window with their corresponding ground-truth IRI.
The next step is data cleaning. The raw smartphone sensor data contains invalid records that must be removed. Among the collected 1.82×10^7 sensor data, the number of "NaN" in the accelerometer, gyroscope and rotation sensors are 6.06×10^3, 1.02×10^3 and 1.38×10^6, respectively. These "NaN" records were imputed with the local mean, which was calculated from data points in the same segment where the "NaN" record sits. Moreover, it is worth noting that the profiler does not record an IRI when the travel speed is less than 20km/h. Hence, there was no ground-truth IRI (label) for some segments and as a result, the corresponding smartphone data was also removed. In addition, road roughness may not excite movement of the vehicle body when the travel speed is low. In this study, the minimum speed was set as 20km/h and response data recorded below this speed was also excluded.

Experiment

Multilayer perceptron training - Module 1

This section elaborates on the training of the MLP-based IRI-estimation model. Statistical and frequency features were extracted from the signals collected from the tri-axial accelerometer, the gyroscope, and the rotational sensor. Statistical features were chosen according to related empirical work (Souza et al., 2018), including mean, median, average magnitude value, standard deviation, zero-crossing rate, skewness, kurtosis, entropy, maximum-to-minimum difference, root mean square level, peak magnitude to RMS ratio, the mean number of peaks, crest factor and IQR (Interquartile Range). On the other hand, after applying Fast Fourier Transform (FFT) to the time-domain signal, 6 frequency features including spectral entropy, spectral irregularity, flux, bandpower, max peak and max peak location were computed. Additionally, categorical features such as car model and mounting device type were also included in the feature set. Consequently, when provided with a label (IRI value), the input to the DL model comprises a vector with a dimension of 258, encompassing 256 numerical features and 2 categorical features.

In the training process, the Adam optimiser was employed with a parameter learning rate of 1e-3. The networks underwent training with a batch size of 128, a seed value of 777 for reproducibility, and a total of 50 epochs. The framework used to construct the model in this study was TensorFlow (TF). In this study, 80% of the pre-processed data was allocated for training the model, while 10% was reserved for validation to fine-tune the model and optimise hyperparameters. The remaining 10% of the data was kept for testing. Different model structures were trialled and the fully connected layers with neurons of 128-256-512 performed the best. The model achieved an root-mean-square error (RMSE) of 0.57, as shown in Figure 7. The R-square of the linear regression between the estimated and ground-truth IRI was 0.79, as demonstrated in Figure 8. The calculation of RMSE is shown in the below formula.

$$\mathrm{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}$$

$\boldsymbol{n}$: The number of samples,
$\boldsymbol{y_i}$: Ground-truch IRI ,
$\boldsymbol{\hat{y}_i}$: Predicted IRI.

Semi-supervised learning - Module 2

Besides the labelled data, unlabelled data is generated when vehicles drive on road networks whose ground-truth IRI is unknown. Based on these data, VIME was adopted as the semi-supervised learning methodology. The hyper-parameters (learning rate, p_m, and alpha) and output dimension were subsequently refined to align more suitably with the objectives of our work. After applying the SSL algorithm, the performance of the original DL model developed in Multilayer perceptron training - Module 1 improved, as evidenced by the lower RMSE, indicated in Figure 9.

A systematic validation procedure was undertaken to evaluate the efficacy of VIME. A predetermined label rate, ranging from 30% to 90%, was set to extract a labelled subset of the initial entire labelled dataset. The selected labelled subset was then employed to train the supervised model elaborated upon in Section Multilayer perceptron training - Module 1. Simultaneously, the remaining data was regarded as unlabelled data, and the encoder in the VIME algorithm was trained using this unlabelled data to learn the underlying feature patterns and generate a novel representation for each sample. Then, the labelled subset data along with the representations of the original unlabelled subset were both used to retrain the model. This semi-supervised trained model was then compared with the model trained exclusively using the labelled data subset. This study trialled different label rates ranging from 30% to 90% with a step of 10%, and the RMSE values of the two streams of models are plotted in Figure 9. It is shown that both lines go downwards as the label rate increases, indicating that the performance of both models improves with more labelled data. However, it should be noted the SSL-trained model consistently sits marginally below the fully supervised-trained model, suggesting that the SSL-trained model achieves a lower RMSE, and therefore shows a better performance across the entire label rate range. It should be noted that the improved performance is not solely attributed to using more data, and the implication is that leveraging both labelled and unlabelled data to capture underlying patterns more effectively improves the model's generalisation and performance on unseen data.

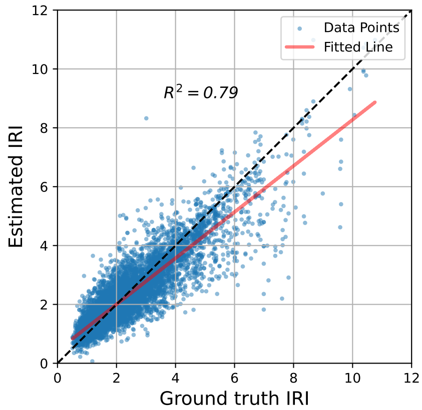


Figure 8: Estimated IRI vs Ground truth IRI datapoints and regression line.

Discussion

This section summarises the contributions of the proposed SSL framework, discusses the limitations of the methods developed, and suggests the areas of future research that promote the application of data-driven sRIE systems.

Contributions

Our study advances the field of data-driven road roughness evaluation, by introducing an SSL framework that leverages real-world data. Key contributions include:

Considering the real-world practical set-up challenges.

This is the first study to simultaneously utilise real-world data while accounting for variations in car models and

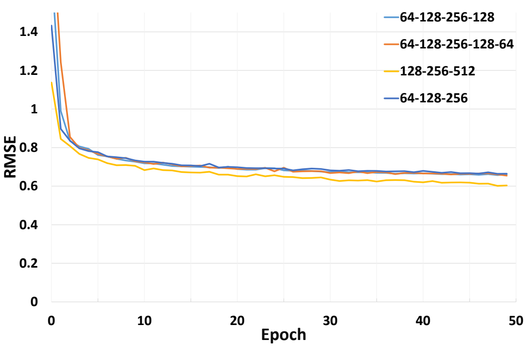

Figure 7: The MSE vs Epoch plot between different MLP model structures using validation dataset.

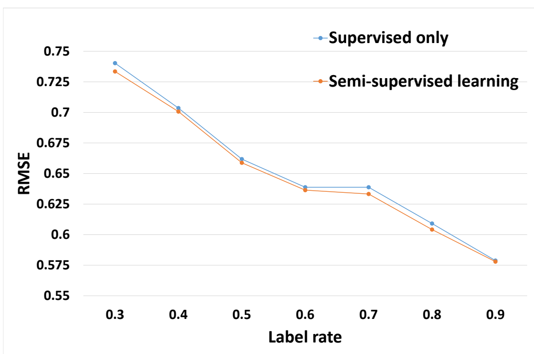

Figure 9: RMSE of the fully-supervised and semi-supervised models in different label rates.

mounting devices, unlike previous studies that worked on simulated vehicle responses or involved single vehicle and mounting configuration.

Adopting SSL to leverage unlabelled data.

Extending the application of SSL in data-driven infrastructure health monitoring, our study validates the idea of using limited labelled data while leveraging the crowdsourced unlabelled data to improve the model's performance, as demonstrated by the lower RMSE values. It's important to note that this improvement partially results from the inclusion of additional unlabelled data, which results in a more comprehensive dataset than what is available to fully-supervised models. Our findings underscore SSL's potential for scalable and cost-effective infrastructure monitoring, especially in contexts where labelled data is limited.

Setting a benchmark for SSL-based pavement roughness evaluation.

By integrating semi-supervised learning with real-world data collection, our proposed framework utilises both specialised survey instruments and public vehicles, and the SSL method yielded a lower RMSE than the model trained with full supervision. This study sets a benchmark for future studies exploring this field and contributes to the knowledge of a scalable and cost-effective approach for real-time pavement roughness monitoring.

Limitations

Limitations of this study are acknowledged:

Ground-truth data imbalance.

As an inherent property of the experiment route's roughness, the ground-truth IRI data is imbalanced, as illustrated in Table 1. Specifically, the ground-truth data sit mostly in the range of 0-4 mm/m and lacks in high IRI ranges (above 6 mm/m) and such imbalance limits the SSL algorithm's performance. Since the SSL algorithms involve learning the patterns of the unlabelled features, and due to a lack of response data for high-IRI road segments, there is not enough data for the algorithm to learn the patterns from. As a result, the SSL can exhaustively learn the complete patterns of features in the low-IRI range, and improves the model's estimation accuracy in this range better than that on the high-IRI range.

Limited semi-supervised learning method.

This study only explored one SSL method, namely VIME. While VIME has shown promising results in our context, our study struggled to find other open-sourced SSL methods that work on tabular data features, instead of the image data, which is predominantly studied in SSL. The improvement in the model's accuracy achieved in this study using VIME does not represent the benefits that generic SSL methods could provide in this application context.

Resource intensity of Semi-supervised learning.

Under the context of crowdsourcing-based road roughness monitoring, crowdsourced smartphone sensor data could become resource-intensive, in terms of computational power and data storage. Moreover, SSL techniques involve iterative mutation of the raw data, posing challenges for scalability and real-time data processing, which could be crucial for data-driven monitoring approaches.

Future works

Implementation using crowdsourced data

Our research has validated the effectiveness of using SSL techniques to leverage unlabelled data in training the IRI estimation model. In the next stage, the team plans to engage crowdsourcing participants to collect unlabelled data in real-world scenarios. It is expected that more variations exist in the public participants' practical set-ups and the response data collected under such conditions contains underlying patterns that could be learned by self-supervised and semi-supervised learning algorithms. Consequently, by accounting for these variations, a more robust and adaptable estimation model could be developed.

Dependency on participant compliance

Crowdsourcing relies on the active and correct usage of our data collection app by participants and the robustness of collected data depends on the participant's compliance with collection rules. Such an issue, which exists in crowdsourcing-based research studies, becomes more critical when the scale of the data collection grows. Hence, strategies to enhance participant compliance and retention become necessary. These strategies could may more engaging App user interfaces, regular reminders, incentives aligned with long-term participation, etc., and can be explored in future research.

Incorporating connected vehicles in RIE

While this study adopted smartphones as the roughness data collector, the prevalence of connected vehicles has drawn research focus. These vehicles are equipped with GPS and motion sensors and the data is uploaded to the manufacturer's servers, providing a rich data source. However, the integration of data from connected vehicles in the proposed SSL framework poses many challenges. One of the primary concerns is addressing inaccuracies that may arise from differences in vehicle types. Identifying and rectifying these inaccuracies is crucial to ensure the validity of roughness monitoring using this approach.

Applying other SSL methods

A comparative analysis of other SSL techniques could be explored in future research. Such exploration would also enable a more comprehensive understanding of the strengths and limitations of various semi-supervised learning strategies in this application context.

Conclusion

This study proposed an SSL-based framework for IRI estimation and validated its effectiveness using real-world data. Smartphone-collected vehicle response data was collected from different mounting configurations and vehicle models. An MLP-based IRI estimation model was first trained and an SSL algorithm (VIME) was adopted to learn patterns from the unlabelled data and to generate new representations of the data features used to predict the IRI. The results suggest that the SSL-trained model achieves a lower RMSE than the fully supervised trained model, when the same amount of labelled data was provided. Our study adds to the body of knowledge in smartphone-based road roughness monitoring by 1) developing an IRI-estimation model trained using real-world vehicle responses, considering the vehicle and mounting variations, 2) proposing an SSL framework that leverages both labelled and unlabelled response data, 3) improving the accuracy of an existing model by using SSL techniques, and 4) validating the benefits of incorporating SSL in crowdsourced pavement roughness monitoring.

Acknowledgments

This research work is part of research projects (Project No. 2.7 and No. 3.4) sponsored by the SPARC Hub (https://sparchub.org.au) at the Department of Civil Engineering, Monash University funded by the Australian Research Council (ARC) Industrial Transformation Research Hub (ITRH) Scheme (Grant number: IH180100010). MONITORING CONCRETE POURING WITH KNOWLEDGE GRAPH-ENHANCED COMPUTER VISION: A CASE STUDY FROM MUNICH, GERMANY

Fabian Pfitzner[1], Songbo Hu[2], Alex Braun[1], André Borrmann[1], and Yihai Fang[2]
[1]Chair of Computational Modeling and Simulation, Technical University of Munich, Germany
[2]Department of Civil Engineering, Monash University, Australia

Abstract

This paper introduces a novel approach for monitoring concrete pouring. Traditional manual tracking methods are tedious, while automated solutions, such as Computer Vision (CV)-enabled methods, are challenged with occulted data and limited adaptability to diverse crane behaviour patterns. We propose a knowledge graph-enhanced CV method that combines context knowledge with object recognition. This approach analyses tower crane behaviours and their interactions with workers, truck mixers, and building elements, providing a detailed and resilient interpretation of concrete pouring progress. Preliminary findings reveal the method's capacity to interpret incomplete data and comprehend complex site dynamics, demonstrating promising potential in a real-world scenario.

Introduction

Concrete pouring is a common and critical construction activity, significantly impacting both the completion time and cost of construction projects (Wang et al., 2022). The crane plays a pivotal role in this activity, as the "crane-and-skip" method emerging as one of the most prevalent techniques for concrete pouring (Lu et al., 2003). In this process, concrete is mixed and then poured into the skip on the ground by workers; then the crane lifts the skip to one or more locations requesting concrete; once in position, the skip is tilted or manipulated to pour, before the empty skip is lowered back to the mixer for refill.

Traditionally, monitoring the progress of concrete pouring processes has been manual and approximate, where the total volume of concrete delivered to the site is used as an indirect indicator of pouring progress (Lu & Anson, 2004). This method merely provides a rough estimate of the progress, and cannot capture nuances related to the pouring process, such as the cycle time of crane lifts and the waiting time of truck mixers. Consequently, it provides limited insight into the bottlenecks of critical site resources (e.g., crane availability) and yields minimal contributions to crucial decisions that impact site productivity (e.g., hiring extra cranes) (Hu et al., 2021).

To gain insights into the pouring process, which requires a large volume of data, Computer Vision (CV) has emerged for automated data acquisition and analysis. For instance, Gong and Caldas (2010) developed a CV-based method to track crane hooks and concrete buckets (i.e., skips), enabling the analysis of concrete pouring states (e.g., bucket readiness, pouring into specific columns) and cycle times. Nevertheless, these CV-based methodologies often confront adaptability challenges. They rely on the assumption of continuous and uninterrupted concrete pouring, following an overly rigid crane behaviour pattern in each pouring operation (e.g., the buckets have to return to the mixer after each pouring). Meanwhile, these methods often necessitate project-specific parameters, such as designated loading and unloading zones, to streamline data interpretation (Yang et al., 2014).

These rigid rules in data analyses often misalign with the dynamic environment of construction sites, leading to inaccurate data interpretations and limited generalisability in different construction projects. Compounding this issue are hardware limitations, such as cameras missing crucial frames or occlusions blocking the view. These limitations will also disrupt the crane behaviour pattern recognition, leading to inaccuracies or frequent relocating of cameras.

Therefore, an adaptable reasoning mechanism is required that ensures enhanced robustness and greater generalisability for monitoring concrete pouring. Knowledge Graphs (KGs) offer significant potential to elevate the reasoning capabilities of CV systems (Fang et al., 2020). KGs enable machines to comprehend complex relationships and enriched contexts within data, going beyond mere visual recognition (Pfitzner et al., 2023a).

By integrating KG and CV, the authors propose a universally adaptable interpretation of concrete pouring processes. In later sections, the paper includes a literature review on concrete pouring monitoring and KG-enhanced CV systems in the construction industry, followed by a detailed description of our methodology and a case study from an active construction site in Munich. It concludes with a discussion of the method's contributions, limitations and potential improvements.

Literature review

Methods of Monitoring Concrete Pouring

Over the past decades, continuous research has focused on monitoring concrete pouring, with relevant studies summarised in Table 1. Initially, this monitoring was mainly for quality control, aiming to predict concrete curing conditions and strength development (Moon & Yang, 2017). The process involved manual documentation of the concrete pouring time into formwork and environmental factors, such as humidity, to ensure compliance with curing standards.

Table 1: Literature on Monitoring Concrete Pouring

Reference	Year	Tracked item	Tracking Mechanism	Collected data	Outputs	Limitation
(Lu & Anson, 2004)	2004	Concrete Mixer	Retrieving information from manually prepared documents	Site arrival /departure time; Location and element type for pouring; Pouring method.	A productivity evaluation (i.e., volume/time) for different pouring methods	A coarse granularity of tracking at a dozen of truck trips level; Not revealing delays in concrete pouring states and related resource bottlenecks.
(Moon & Yang, 2010)	2010	Concrete Mixer and concrete pump	Radio-frequency identification device (RFID)	Site arrival time, mixer entering/ leaving work zone time.	Total amount of poured/remaining concrete; Average pouring speed; Estimated time to complete.	A coarse granularity of tracking at a truck trip level; Manual installation of RFID tags; Not revealing delays in concrete pouring states and related resource bottlenecks.
(Gong & Caldas, 2010)	2010	Bucket	Computer Vision (CV)	Buckets' presence in user-specified waiting zone and column zones; Buckets' absence (indicating their loading).	Durations of each user-defined pouring states for a particular pouring activity.	Assuming uninterrupted pouring; The case study merely focuses on the pouring of two columns; Relying on fixed states in the column pouring and site-specific spatial context; Requiring meticulous/dynamic planning of camera locations.
(Yang et al., 2014)	2014	Crane jib	Computer Vision (CV)	Crane jib trajectory and its overlap with site layout.	State durations of concreting pouring and non-concrete pouring activities.	Assuming concrete mixers' locations are fixed; Replying on site-specific spatial context and observed probability when differentiating concrete pouring states.
(Danel et al., 2022)	2022	Crane	Crane inbuilt motion trackers and load sensor	Slewing angle, trolley distance, hoist height, and load weight.	State durations of concreting pouring activities.	Assuming uninterrupted concrete pouring process; Relying on a standard crane behaviour pattern.
(Wang et al., 2022)	2022	Crane cable and bucket	Computer Vision (CV)	Concrete buckets' presence in a meticulously planned imaged area (e.g., on the top of the dam to be poured).	Cycle time of crane lifts.	Assuming uninterrupted concrete pouring processes; Relying on a standard crane behaviour pattern; Requiring meticulous locating of camera; Not revealing delays in concrete pouring states and related resource bottlenecks.
(Kim et al., 2023)	2023	Sound	Classifying site sound with deep-learning algorithms to recognise concrete pouring	Acoustic signal from construction sites.	Start and finish time of concrete pouring; Abnormal concrete pouring such as the impact sound of the vibrator's formwork and the sound of concrete slowly leaking.	Focusing on the safety of concrete pouring; Not revealing productivity-related insights (e.g., cycle times).

Lu & Anson (2004) analysed hundreds of digital quality control records to explore the link between concreting speed and pouring methods. Their work provided significant insights for enhancing productivity through method selection. However, their reliance on manual data collection leads to a coarse tracking granularity (e.g., dozens of truck mixer trips) and restricts insights for site management.

The introduction of IoT devices creates a shift towards automated, sensor-based tracking methods. Moon & Yang (2010), for instance, employed RFID technology to monitor the movement of truck mixers on-site, enhancing tracking to a granularity of individual trips. Kim et al. (2023) used acoustic sensors combined with deep learning algorithms to pinpoint the state when concrete is poured into formwork. While it does not monitor every state of the concrete pouring process, such as loading the concrete, this method further refines the granularity for tracking to specific pouring states. Danel et al. (2022) further advanced the tracking by using in-built crane sensors to monitor every state of the concrete pouring process, thereby uncovering prolonged delays caused by resource miscoordination. However, IoT methods often struggle to gather context information efficiently, limiting their ability to correlate lift operations with overall construction progress.

Recent research has turned to CV for more nuanced monitoring. CV methods typically consist of two steps: object recognition and reasoning. Object recognition identifies concrete-related resources in images, while reasoning interprets the actions of these objects. Gong & Caldas (2010) were among the first to apply CV in this field. They detected concrete buckets and mapped them onto predefined work zones in the images to identify specific pouring states with an accuracy of 84.7%. However, the need for user input limited their method's applicability. In contrast, Wang et al. (2022) applied CV to dam construction, tracking concrete buckets and crane cable interactions to indicate pouring cycles, achieving an even higher accuracy (>99%). However, the method assumed an uninterrupted pouring process, which is unrealistic for building construction. Yang et al. (2014) focused on crane jib recognition to track crane movements in relation to site layout plans, allowing for the recognition of mixed crane operations (i.e., concrete pouring and other lifting activities). Yet, this required distinct separation of concrete and other materials' loading zones and relied on observed site-specific probabilities in the reasoning process, potentially limiting adaptability to other sites.

In addition to the generalisability issue, one of the main challenges with these CV methods is their struggle to correlate crane operations with specific building elements and to detect the particular causes of idling. For example, they were often unable to identify scenarios where concrete buckets were in position but left unattended. These limitations highlight the imperative need to develop a reasoning mechanism that can adapt to varied site-specific parameters (e.g., site layouts) and effectively highlight the interactions between concrete pouring resources (e.g., cranes, buckets, workers, and mixers) and construction products (e.g., building elements).

Leveraging the Knowledge Graph to Enhance CV in Construction Applications

Knowledge Graphs (KGs) are poised to significantly augment the reasoning capabilities of CV, providing a universally applicable, generalisable context. By focusing on universal heuristics, such as the spatial relationships among objects (e.g., workers), KGs actively process and interpret CV outcomes, transforming raw data into information and enabling the derivation of new insights. In the construction industry, KG-enhanced CV systems have shown particular promise in safety management. Fang et al. (2020) demonstrated this by developing a KG-based CV system that identifies potential hazards through the spatial relationships among workers, PPE, and heavy machinery. Lee and Yu (2023) employed a KG to standardise and identify safety hazards in mobile scaffolding use, effectively pinpointing common misuses, including absent outriggers or missing guardrails. Both KGs perform spatial analysis of relevant objects to identify unsafe conditions or behaviours.

Unlike unsafe behaviours that often occur in isolated instances, construction activities, such as concrete pouring, typically consist of multiple states following a specific sequence. Therefore, solely specifying spatial relationships may only allow for a rough productivity evaluation at a broader level (e.g., site level) rather than recognising specific construction activities (Pfitzner et al., 2023a). To link planned sequences to actual site conditions, Braun et al. (2020) proposed a graph-based method to derive construction sequences from BIM models, overlay the sequence with detected objects, and thereby compensate for data gaps caused by occlusions. This application underscores the capability of KGs to embed sequence information.

However, the sequence of concrete pouring states (i.e., lifting states) is more dynamic. Addressing this challenge, Hu et al. (2023) utilised a KG to organise heterogeneous data from motion trackers, weight sensors and images for recognising crane lifting states (e.g., pick-up, suspend). This approach embeds dependencies of states instead of a standard sequence to allow flexibility. Thus, it is able to understand complex operations, such as those with multiple unloads in one lift. Despite its effectiveness in crane operation recognition, Hu et al.'s approach falls short in differentiating concrete pouring from other lifting activities and in linking crane operations to specific building elements. Moreover, their method is not tailored for enriching CV data. This underscores the necessity for a specialised KG tailored for concrete pouring processes and CV data formats. Such a KG should be proficient in interpreting concrete pouring operations, distinguishing between various lifting activities and linking pouring operations to building elements seamlessly.

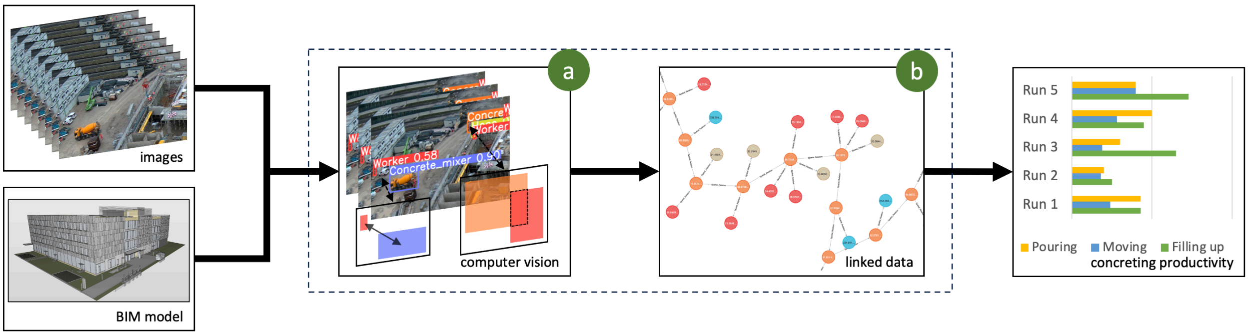

Figure 1: Overview of pipeline

Methodology

Overview of the approach

The scope of this study is to determine the utility of the crane in concrete pouring activities and associate crane operations with building progress. The underlying purpose of activity monitoring is to optimize the coordination of concrete delivery schedules, thereby mitigating overproduction and minimizing material waste during concrete pouring. Streamlining the concrete pouring process could condense construction timelines and elevate resource utilization.

We use semantic knowledge derived from the state dependencies in concrete pouring and BIM model to fuse CV object recognition results. As a result, we automatically monitor the pouring process in fine granularity (i.e., states), with the elapsed time of distinct process states recorded to provide precise insight into the required time for pouring diverse building zones. The results are anticipated to facilitate detailed control of construction progress.

The CV-based pipeline, shown in Figure 1, is developed to convert raw image and geometry data to precise process-level information. Instead of using data-heavy video streams, a low frequency of input images is chosen to avoid extensive computation times for processing long construction periods.

CV methods (a) are applied to extract information from the images. This step includes interpreting spatial dependencies in the context of the concrete pouring phase. In addition, the information is mapped to the BIM model using grid-based zones.

The knowledge graph (b) is used to determine unseen states and to link the as-planned geometry data. Unknown states are predicted based on their predecessors and successors. This predictive capability is particularly valuable in addressing data acquisition limitations, such as missing frames or occlusion, ensuring a robust analysis of individual pouring states while considering the as-planned quantities.

CV-based state recognition

The computer vision part contains three steps: Object detection, spatial-temporal reasoning, and geometric projection.

A YOLOv8 model is used for object detection, covering the following classes: concrete_bucket, hook, concrete_mixer, hose, and worker. The model is deployed on image sequences representing the concrete pouring states. Figure 2 illustrates the distinct states of the concrete pouring process: Loading the concrete bucket at the concrete mixer, moving the bucket to the building element, and filling the building element's formwork with concrete. To derive these instant states from the images, spatial reasoning is necessary.

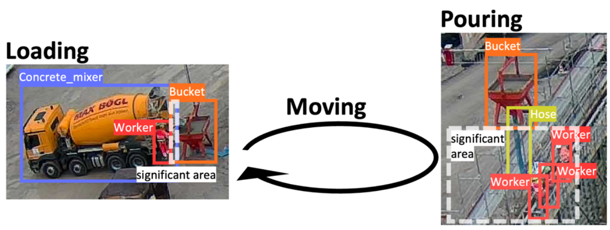

Figure 2: Spatial relationships of concreting cycle

In the case of crane-and-skip concrete pouring, the location of the concrete bucket and its relation to other elements defines the current action. Fig. 2 shows the essential scenarios of the concrete bucket to determine the process state: "Loading", "Moving", and "Pouring". At the start of the process, the concrete bucket moves close to the concrete mixer to be filled by a worker. The bucket stays for a period of time (e.g., 30s) and then gets lifted by the crane. Intersection over Union (IoU) is used to determine the bounding boxes' spatial dependency.

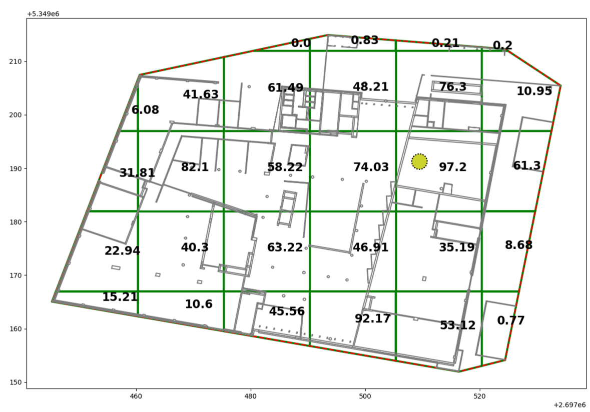

Figure 3: As-planned zones and volumes [m³] derived from the BIM model and projected base point of the hose (light green).

Subsequently, the bucket moves to the building element, and the pouring state starts. During the pouring state, a hose is rolled down, and a worker controls the nozzle of the hose to fill the formwork. Like in the "Loading" scenario, the activity is derived by interpreting the spatial relationships of the bounding boxes using IoU. During the "Pouring" state, workers and the hose are within the area underneath the bucket. The "Moving" state is computed based on the known order of process steps, discussed in the following section.

To compare the as-performed pouring volumes to the as-planned volumes, the image information is enriched. First, the as-performed quantities are computed using known volumes of the concrete mixer and bucket. Second, the as-planned volumes are generated using the BIM model, illustrated in Fig 3. The quantities of the BIM model are computed storey-wise to specific zones of a grid. The grid contains the quantity of all building elements within one zone. The location of the hose is projected to the BIM model using a perspective transformation approach presented by the authors in previous publications (Pfitzner et al., 2023b). As the hose traverses a specific zone, the as-performed data gets linked with the as-planned data. Based on the expected concrete amount of a specific zone, the amount of poured concrete is validated. Moreover, the amount of wasted concrete can be detected. A detailed investigation of geometry mapping is outside this paper's scope and will be discussed by the authors in future publications.

Ontological model for process reasoning

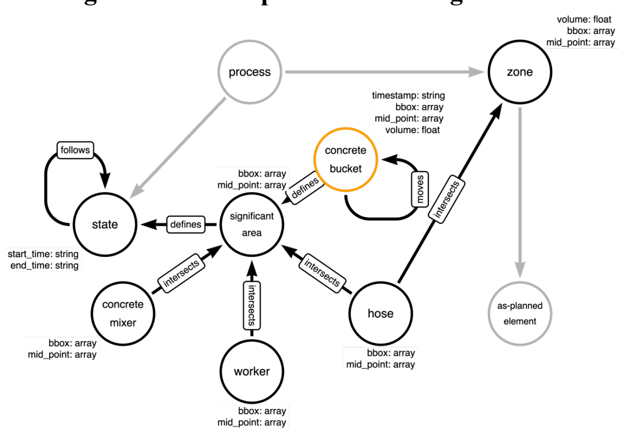

Figure 4: Ontological model

The ontological model, shown in Fig. 4, is designed according to the states representing the concrete pouring process. The process's states are defined by the time-dependent actions of the concrete bucket. As such, the bucket nodes have a timestamp property and a relationship to their predecessors and successors. This ensures that the bucket's current, past, and future actions can be determined based on the bucket's significant area. The significant area is defined by typical construction-related dimensions; it encompasses the space beneath the bucket and incorporates a buffer, considering the objects utilising the bucket manifest beneath it.

Unseen states are parts of the process that cannot be detected on the frames. This is the case when the concrete bucket moves. The predecessor and successor relationships are utilised to compute the missing information. The unseen states of the concrete pouring cycle are determined based on the four different relationship patterns shown in Fig. 5. If the detected state changes, the bucket's state is considered to be "Moving" in between, encompassing both scenarios "moving from mixer" and "moving from building elements". In addition to that, the appearance of the concrete mixer is an indicator of pouring. If there is no mixer on-site, the crane is not involved in the pouring process.

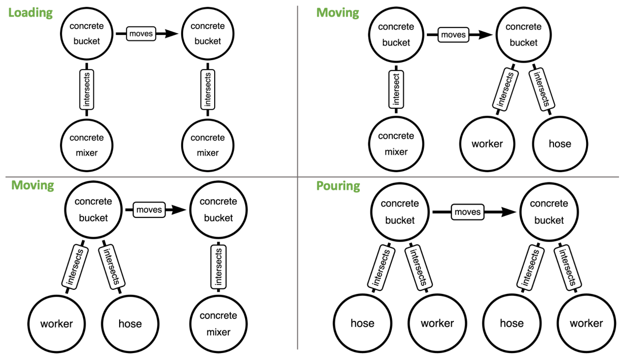

Figure 5: Relationship patterns for process reasoning

Once the relationship patterns are detected in the graph, the state information is stored in the equivalent state nodes. Subsequently, the process chain is created by sequential states containing start and end times. This has the advantage of querying the elapsed times straightforwardly. The start of the process chain is defined by the first time the concrete bucket gets loaded by the concrete mixer. The process chain ends once the bucket no longer returns to the concrete mixer and has moved away from the element. The link to the as-planned zones is created through the projected tip of the hose once it intersects with the corresponding zone. The process chain is used to investigate the elapsed time of individual states, the number of cycles, and the amount of concrete used during the process.

Case Study

The case study, shown in Fig. 6, was conducted on a building construction project near Munich, Germany. The building was partially constructed using cast-in-place concrete pouring.

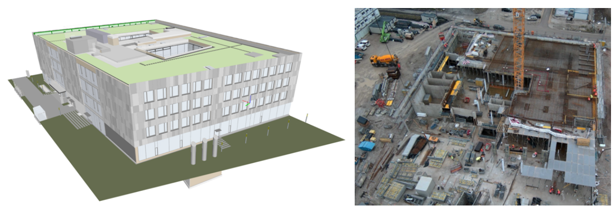

Figure 6: BIM model and crane camera perspective from the construction project

Data and setup

The images were taken every 30 seconds from fixed crane cameras at diverse heights and perspectives. The dataset consists of a total number of 270k images. The annotated image dataset containing 325 images was split by 80/20. An additional model trained on the MOCS dataset (Xuehui et al., 2021) was included in the pipeline to detect workers. The model training on a Nvidia RTX 8000 GPU took 0.98 hours. To receive the as-planned geometry, we used an existing IFC model of the building. A Neo4j server was set up in a docker environment to host the labeled property graph. Four concrete pouring examples were investigated with a total number of 623 images.

Results

The YOLOv8 model was trained on 79 epochs and reached an mAP score of 92.1 %, as shown in Table 2. The hose class performed weaker than the other classes due to fewer occurrences in the dataset.

Table 2: Object detection results

class	Precision	Recall	$mAP^{0.5}$
bucket	92.6%	98.3%	97.7%
hook	97.6%	96.9%	99.2%
concrete mixer	98.1%	97.4%	97.8%
hose	87.3%	77.8%	73.5%
all	93.9%	92.6%	92.1%

The model was deployed batch-wise using a self-implemented PyTorch-based environment. The extracted image information was inserted into the Neo4j graph database using the Python library neomodel and the ontological model, illustrated in Figure 4. Using the distinct relationship patterns, the state nodes were generated and integrated into the graph. Based on the start- and end-time attributes of the state nodes, the elapsed time was queried. The buckets' bounding boxes, timestamps, and the particular concrete pouring states were annotated across two datasets to evaluate the ground truth of all states. The first dataset contained 119 samples; the second dataset contained 184 samples.

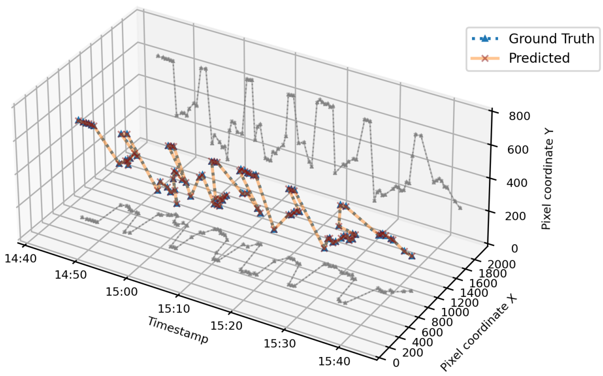

Figure 7: Comparison of the bucket's pixel coordinates between ground truth and detection result in dataset 1

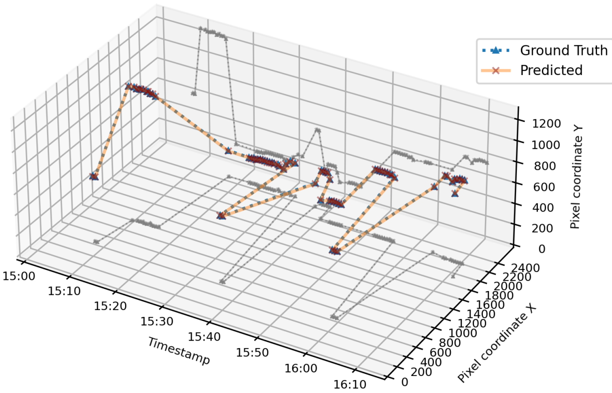

Figure 8: Comparison of the bucket's pixel coordinates between ground truth and detection result in dataset 2

Figures 7 and 8 illustrate the bucket detection accuracy by comparing the coordinates of the buckets' bounding boxes against ground truth data. The comparison is conducted over all timestamps across the two datasets, providing insights into the accuracy of the detection algorithm relative to the actual positions of the buckets. The predicted pouring states compared against the ground truth are shown in Figures 9 and 10. A state accuracy of 92.44% was achieved for the first dataset and 95.11% for the second dataset. The consistency and precision depicted in Fig. 7 and 8 underscore the robustness of the bucket tracking mechanism. However, Fig. 9 and 10 show some challenges in the state reasoning. Our method performed better on the second dataset due to the lower frequency of cycles.

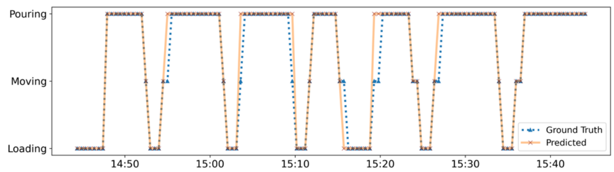

Figure 9: States of the pouring phase in dataset 1

In particular, states with shorter durations are more challenging to detect. It is important to note that exact moving times cannot be computed for the rare cases of moving time below the frames' interval (30 seconds).

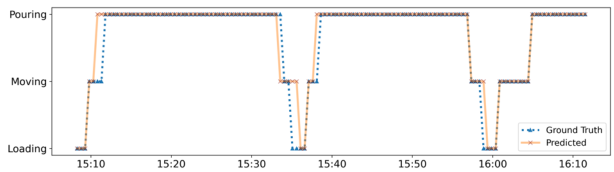

Figure 10: States of the pouring phase in dataset 2

We investigated the elapsed time of four different concrete pouring samples with the introduced pipeline. The times of the individual phases and the number of cycles are shown in Table 3. In general, pouring consumes most of the time. The results show that the process's time can significantly vary depending on the construction scenario.

In certain situations, precisely when waiting for the following concrete mixer's arrival, the moving time of the bucket substantially differs. Moreover, factors like location and size of building elements play a substantial role. To allow further investigations, the amount of concrete volume was calculated based on the IFC model and included in the approach. For this step, the geometry from the IFC model was derived and processed using IfcOpenShell. Based on the building floor, the building elements' vertices were projected to the corresponding 2D floor, and polygons were generated to define the building elements' region, shown in Fig. 3. The grid was created using 15x15 metre cells. All building elements within a cell were considered and summed up to get the total volume amount of the cell. Finally, the correlating grid cell was determined based on the projected basepoint of the hose's bounding box and linked within the graph. Further studies of this topic will be included in future publications of the authors.

Table 3: Elapsed time of the specific cast-in-place states

Sample	No. 1	No. 2	No. 3	No. 4
No. cycles	7	2	7	3
Loading	0:13:06	0:05:04	0:20:44	0:03:31
Moving	0:04:12	0:05:05	0:23:24	0:11:11
Pouring	0:34:52	0:10:06	0:54:04	0:45:31

Discussion and Future Work

The case study results validate the feasibility of our proposed KG-enhanced CV approach in monitoring and analysing the concrete pouring process. Capturing images at 30-second intervals ensures sufficient granularity, achieving 92.44% and 95.11% accuracy in identifying concrete pouring states. This accuracy surpasses previous efforts, such as the 84.7% reported by Gong & Caldas (2010).

With satisfactory accuracy, the case study also demonstrates our methods' superiority in flexibility and extensibility through our innovative adoption of KG in enriching CV systems. Traditional CV methods have a limited application scope, often requiring site-specific model training and manual annotations for critical areas, with a lack of correlation between crane operations and construction progress. Our approach uses CV to identify basic construction objects like workers, concrete mixers, and buckets, enhancing detection success.

The KG then streamlines their relationships with semantic context, enabling a generalisable data interpretation that adapts to changing construction contexts (e.g., concrete loading areas) without reprogramming. This facilitates efficient and resilient processing of diverse data across various construction stages, even different projects. Additionally, this method employs grid-based mapping to indirectly link crane operations with building elements. Although this connection is approximate, it can be further refined to recognise the specific elements being poured based on the positions of workers in a particular zone.

As a result of this method, the data on concrete pouring states offers a dynamic, real-time view of on-site resource coordination, uncovering subtleties often missed in traditional monitoring. For instance, KG analysis reveals that prolonged "moving states" usually miss workers who operate the nozzle. This indicates time wasted mobilising workers, suggesting potential optimisations in pouring sequences. For instance, pouring activities should prioritise the occupied zones to minimise workers' travel. It also informs future development of our ontological model, where tracking worker movements could be valuable as it can highlight unnecessary movements.

Despite its innovative aspects, our approach has limitations. Currently, it focuses on crane-and-skip methods, with pump-based pouring scenarios outside our scope. Meanwhile, its success hinges on accurately detecting discrete states based on spatial relationships between construction elements, which can fail in cases of occlusion or distance. In particular, the hoses have a lower detection accuracy compared with other classes, suggesting the vulnerability of current reasoning rules. To address this, additional parameters and reasoning rules could be used to infer pouring states. For example, the distances between concrete buckets and workers, along with buckets' moving speed, can be used for reasoning. Future work will also explore graph-based machine learning, such as graph neural networks, for automated state classification.

Conclusion

This paper introduces a KG-enhanced CV approach to monitoring concrete pouring. By integrating KG with CV, this method offers a dynamic and adaptable system capable of interpreting complex site dynamics and managing incomplete data. Achieving high accuracy rates of 92.44% and 95.11% in identifying concrete pouring states, our approach matches or surpasses earlier efforts in terms of data interpretation accuracy.

The strength of our method also lies in its ability to efficiently process big data with diverse quality and adapt to changing construction contexts, such as varying concrete loading areas, without needing reprogramming. This adaptability extends across different construction stages and projects, showcasing its potential for broad applicability. Additionally, the use of grid-based mapping to correlate crane operations with as-planned BIM models, although approximate at the moment, opens avenues for more precise recognition of specific pouring elements, even when cameras are positioned at a distance.

In general, our approach's real-time data analysis capability offers a nuanced view of concrete pouring-related resources, effectively highlighting miscoordinations. These insights pave the way for optimising resource allocation and improving site productivity. Anticipated further research aims to integrate this KG with semantic knowledge related to the pump-based concrete pouring method and enhance independence from the detection of site-specific or hard-to-recognise objects (e.g., hoses) by analysing the spatial relationships of easier-to-detect objects (e.g., buckets and workers) or employing machine learning algorithms to discover patterns in KG's topology for classification.

In summary, our KG-enhanced CV method represents a significant stride in concrete pouring monitoring, offering improved accuracy, adaptability, and insight into construction processes. It promises to reshape traditional practices, leading to more efficient and effective construction project management.

[2]Shanghai Jiao Tong University, Shanghai, China

Abstract

Nowadays, the complexity of housing design has grown substantially to meet multitudinous requirements (e.g., cost, space, esthetics, sustainability, circularity, and modularity) of diverse stakeholders, which poses great challenges to traditional labor-intensive design processes. Automatic design tools are being developed to assist designers handle tedious work at scale. However, knowledge gaps still exist in harnessing deep learning models to learn from human experience for more efficient design generation while keeping the data understandable and interoperable. Moreover, human-in-the-loop approach is largely neglected in the automatic design tools, which are essential for more customized and user-centered design. This research utilizes graph data to parametrically represent housing designs and graph-representative deep generative models for design generation, which provides an interactive design approach for the users at every step. This method enables deep learning models to semantically understand hidden patterns and knowledge in housing designs and facilitate the human-centered design process by returning feasible and parametric housing design alternatives. All codes can be found at: https://github.com/jlhofland/housing-design.

Introduction

The design process has been identified as one of the most significant elements influencing housing quality (Hamzah et al., 2011). Traditionally, the creation of housing designs has involved labor-intensive, manual processes, relying on the expertise of designers. This conventional approach has been characterized by iterative design revisions and historical references. However, it faces challenges related to scalability and adaptability to evolving societal needs (Williamson and Wong, 2022). In response to these challenges, recent advancements in technology and more specifically in the area of Generative AI have introduced the possibility of partially automating the housing design process (Ko et al., 2023). These advancements have the potential to accelerate design iterations and augment the creativity of the proposed designs (As and Basu, 2021).

While various techniques for automatic housing design generation offer distinct advantages, they also come with some limitations. Generative Adversarial Networks (GANs) have the ability to produce realistic floorplan images (He et al., 2022; Wu et al., 2019). However, the image-based approaches lack interoperability with common architectural applications (e.g., CAD and BIM) (Ko et al., 2023). Moreover, it is hard to incorporate various constraints and user requirements into the image-based floorplan generation models. Graph-based methods like Graph Neural Networks (GNNs) can be a complementary approach which has good interoperability due to its parametric nature and compatibility with state-of-the-art generative models (Guo and Zhao, 2023). Therefore, it is worth noting that a promising approach lies in combining GANs with graph-based methods for their generative ability and interoperability.

Numerous studies have incorporated graphs as semantic representation to guide the floorplan generation with GAN, which could be referred to as graph-constrained Relational Generative Adversarial Networks (RaGAN) (Nauata et al., 2021, 2020; Shabani et al., 2022). By using graphs, the users can more easily input and modify the layout at the semantic level, which provides a user-in-the-loop approach and ensures that the model not only produces functional designs but also aligns closely with the user requirements. Bubble diagrams have long been used as a conceptual tool in housing design for visualizing spatial relationships and zoning (Zheng and Petzold, 2023), which has been widely incorporated as graph input to guide floorplan generation with GANs in existing models (Nauata et al., 2021, 2020; Shabani et al., 2022). However, most of the models only generate floorplans based on bubble diagrams given by users and neglect the room layout arrangement task in the conceptual design stage (Nauata et al., 2021, 2020; Shabani et al., 2022). Moreover, bubble diagrams primarily serve as a conceptual tool in housing design for visualizing numbers and spatial relationships among rooms, which can not incorporate constraints from building boundaries (Zheng and Petzold, 2023). Graph2Plan (Hu et al., 2020) allows for building boundaries as user input and then extracts the layout bubble diagrams and generates floorplans. However, Graph2Plan does not generate the graph but rather retrieves it from a set of similar floorplans from a database. This makes it less flexible as certain input constraints might not coincide with the floorplans in the database. Moreover, the adjacencies between rooms and exterior walls cannot be defined. It is of vital importance to incorporate such conditions if the housing design needs to fit into constraints from existing walls and rooms, which happens a lot in renovation cases. Also, the edge features of the graph are non-configurable, which means it does not allow for interior doors to be specified by the user.

Heterogeneous graphs could offer a more expressive approach for housing design generation by providing a data-driven framework that explicitly encodes the attributes and relationships among different rooms and components (e.g., walls, windows, and doors) (Gan, 2022). Therefore, instead of using bubble diagrams, we develop heterogeneous graphs to capture complex constraints and diverse attributes for more powerful and versatile housing design generation. To achieve higher flexibility, we generate both layout graphs and floorplans by using generative models based on graph representation (Figure 1).

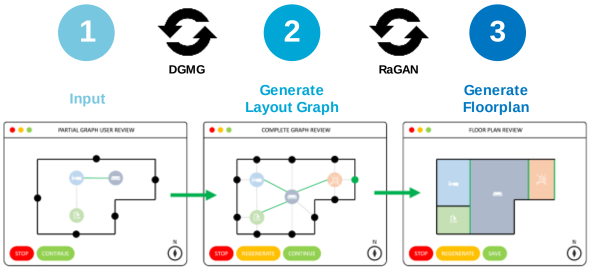

Figure 1: Interactive design generation process where the dots are walls and rooms, and edges represent adjacency. For envisioned graphical interfaces see Figure A4.

Specifically, heterogeneous graph representation will be developed to explicitly encode the attributes and relationships among the exterior walls and rooms which would enable users to input their requirements and constraints (Step 1). Starting from the input, our generative housing design pipeline encompasses layout graph generation model (Step 2) and floorplan generation model (Step 3), which are developed based on DGMG (Li et al., 2018) and RaGAN from Housegan++ (Nauata et al., 2021) because of its wide adaptability and state-of-the-art performance. We made improvements to the models by incorporating edge features in the message passing over heterogeneous layout graphs. On top of this, the user can intervene at each step in the pipeline to make changes to all interim results. By doing this we create a model that proactively keeps the user in the loop and achieves more user-centered design through a collaborative approach compared with end-to-end models (e.g., FloorGAN (Upadhyay et al., 2023)).

Research Methods

Overview

An overview of the pipeline is illustrated in Figure 2, where the top depicts user interaction and the bottom is model training. Starting with the user-input file containing user constraints, augmented DGMG (see next sections) will generate nodes and edges to finish the layout graph. User interaction is available to evaluate the generated layout and make changes along the way. When they are satisfied, the pipeline will pass the layout graph to Hetero-HouseGAN++ (HHGPP, see next sections) for floorplan generation by representing the spatial configuration of rooms through masks, which would then be saved in parametric format. A final user-input step will occur offering to regenerate the plan as necessary.

Initial user input: The user can input the building boundary and specify the location of entrance doors. It is also allowed to provide initial constraints such as the number of rooms for each type. More importantly, the location and adjacency of certain rooms can be specified in the input as partial layout graphs, which is an essential feature for the renovation housing design. It should be noted that only a text-based interface is available for initial user input now, which, however, can be transformed into a graphical interface and embedded into domain applications (e.g., CAD and BIM) in future work. The envisioned graphical interface is depicted in Figure A4.

Generation of layout graph: To generate the customized layout graph based on user input, we adopt a graph generation model based on augmented DGMG (Li et al., 2018). The generated layout graph will explicitly formulate the adjacency relationships of rooms and walls. For instance, a bedroom could be adjacent to the south side of an exterior wall and connected to the north side of the living room through an interior wall with a door. The model will be trained on the large-scale floorplan dataset LIFULL, which was transformed into parametric representation (Nauata et al., 2020). The users can evaluate and modify the generated layout graph or regenerate it based on their preferences.

Generation of floorplan: To acquire the floorplan with precise spatial configurations that fits the layout, we adopt a graph-constraint RaGAN based on Housegan++ (Nauata et al., 2021), which is referred to as HHGPP. The model could aggregate the features of the layout graph through message passing and generate the spatial configuration of rooms as volume masks. The output of

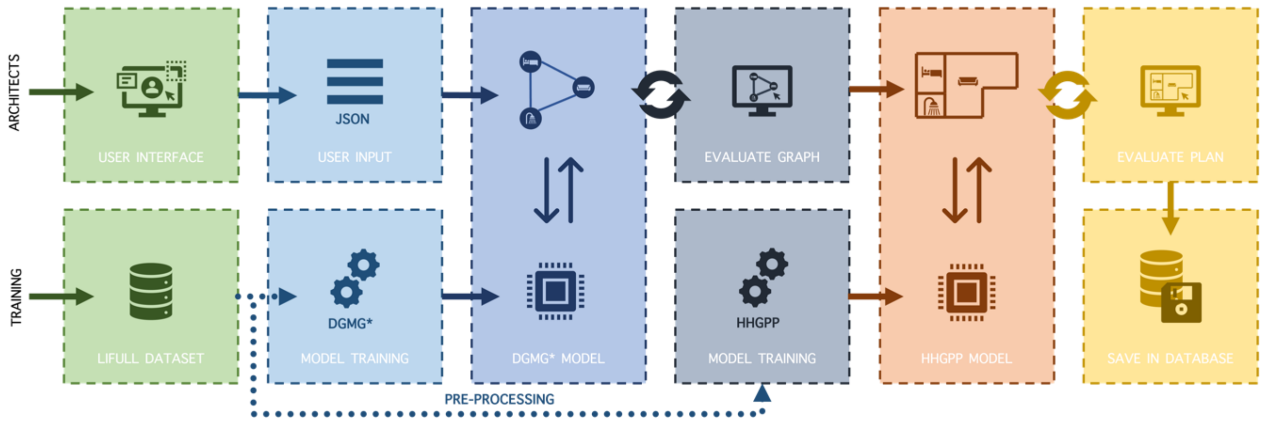

Figure 2: Pipeline for housing design, top: user interaction, bottom: model training

the pipeline will be a parametric floorplan and a graph that depicts the layout arrangement, which can be fed into domain applications for further editing and optimization.

The following sections explain these steps in more detail.

Initial user input

The user could input the requirements and constraints for the housing design(Step 1, Figure 3). The requirements would be represented as a conditioning vector. The constraints would be transformed into a partial graph (Step 2, Figure 3).

User input:

- A vector representing user requirements: the number of various room types, and additional entries indicating if the room quantity is upwards flexible (3 vs 3+ for example).
- The constraints from building boundary and predefined location of rooms (i.e., preferred location of specific rooms or fixed location of existing rooms), transformed into heterogeneous-graph representation: exterior walls as nodes (node features with starting and ending vertices, final element indicating with entrance door or not); corners which connect the exterior walls as edges (edge feature represent the corner type); predefine rooms as nodes (node feature represent room types); adjacency between rooms and exterior walls as edges (edge features represent relative direction); adjacency between rooms as edges (edge features represent the relative direction and connection type (i.e. through a wall or a door, or directly connected)).

Generation of layout graph

In this section, we develop the model to generate layout graphs conditioned on user input by completing the input partial graph from user constraints. User requirements such as the number of bedrooms and bathrooms are fed into the model as a conditioning vector (Li et al., 2018) to generate graphs that meet a client's needs. The graph generation model is based on augmented DGMG, which could incorporate edge features in the message passing for heterogeneous layout graph generation. Through training over a large set of real architect-created home layout graphs (Nauata et al., 2020), the model learns to generate graph layouts that respect various implicitly learned architectural design rules and meet user requirements and constraints.

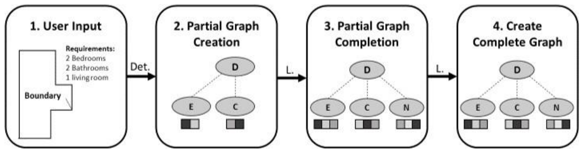

Figure 3 Layout Graph Generation Model. D(decision), E(Add Edge), C(Choose connection), N(Add Node). Det. specifies that the process is deterministic, while, L. states that the step is learned from data.

The layout graph generation process based on augmented DGMG follows an autoregressive generation mode (Li et al., 2018), which is depicted in Steps 3 and 4, Figure 3. The general procedure and our modification are described as follows, and a more detailed illustration can be found in (Li et al., 2018).

Layout graph generation:

(a) Choose to add a new node A (yes/no).

(b) Choose to add a new edge from source node A (yes/no).

(c) If yes:

  i. Choose a destination node B from pre-existing nodes in the graph. In this research, we also predict the feature of the added edge in this step.

  ii. Perform GNN message-passing to update node representations. In particular, we augment DGMG by incorporating edge features in the message passing.

When the model chooses not to add another node, the graph is complete. The output of the model would be a complete layout graph, which could be evaluated, edited, and regenerated through the envisioned user interface.

Generation of floorplan

To generate the floorplans with precise spatial configuration of rooms that respect the constraints specified in this heterogenous layout graph, a graph-constraint RaGAN is developed based on augmentation of Housegan++ (Nauata et al., 2021) (Figure 4).

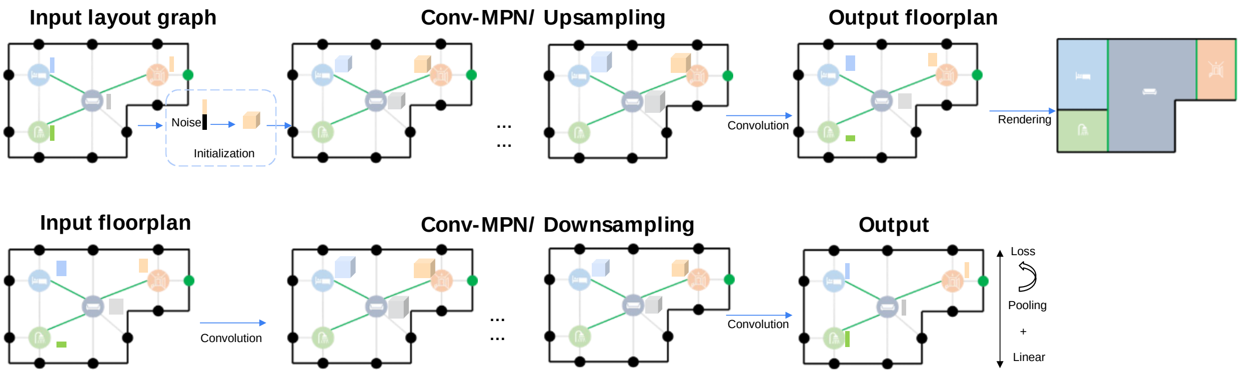

Figure 4 Floorplan generator (top) and discriminator (bottom). ConvMPN is our backbone architecture [9]. The input graph constraint is encoded into the graph structure of their relational networks.

Hetero-HouseGAN++ (HHGPP) is a generative adversarial network whose generator transforms input data (lists of data representing layout graph, e.g. nodes, edges, features, etc.) through Convolutional Message-Passing Network (ConvMPN) into pixel-based room masks. These room masks are later vectorized into parametric representations of floorplans. The discriminator then performs the reverse process, starting with room masks, and resulting in a binary response as to the validity of the room masks it was provided, given the graph data also fed in alongside.

Our improvement in HHGPP compared with Housegan++ includes incorporating new node types, edge types, and node and edge features for graph-constrained floorplan generation. First, GNN message-passing occurs as convolutions over a large data block constructed as the concatenation of the graph node feature volumes, the pooled features volumes of their neighbours which get encoded with the edge type and edge features across these connections, and the pooled feature volumes of the disconnected nodes. These convolutions happen three times, downscaling as we go to result in the final encoded nodal feature volume representations. The second innovation is to use conditional generation whereby some room masks are predefined during mask generation such that the generator learns to paint the remaining masks for the floorplan.

Results and Evaluation

Training data preparation

All the data used for this project are extracted and augmented from the LIFULL dataset (available at: https://www.nii.ac.jp/dsc/idr/en/lifull/), a database of real floor plan designs. Each floor plan is represented as a list of values for room ID and type, room bounding boxes, floorplan edges, edge adjacencies, and IDs of edges with doors. Note that edges here refer to exterior and interior walls, not graph edges.

We filter out floorplans with either completely disconnected rooms or rooms that are only connected at a corner. From this raw data, we create two types of files used for training the layout graph generation model: user-input files and sequences of graph generation. For training the floorplan generation model, we transform the bounding boxes of rooms into the masks (3D volumes) of room nodes to represent their spatial configurations. The pairs of layout graphs and floorplans (graphs with masks for room nodes) will be used to train the generator and discriminator in the HHGPP.

Network training

The layout graph generation model will be trained through teacher forcing throughout the autoregressive generation process of DGMG (Li et al., 2018). The sequences-type files are lists of the ground-truth answers to the sequential generation questions, "should another node be added ?", "what node should this edge be connected to?," such that, when followed, producing the precise home layout graph corresponding to the LIFULL homes. Some decisions in the sequence are binary yes/no responses, while others are multi-class prediction-type responses. In either case, decisions are of a discrete number of choices and proceed by the model calculating a prediction for the logits of each response type. This is a numerical value where a highly positive value represents high confidence in that prediction value being the correct one, while a low or highly negative value indicates low confidence in that option.

We then convert these predicted logits to probability mass values (or likelihoods) via the sigmoid (binary) or softmax (multi-class) equations. Finally, our loss accumulated at each decision is equal to the negative log of the predicted likelihood for the correct response. Minimizing this value then seeks to maximize the likelihood of the correct response. The corresponding loss function is illustrated in (1):

$$loss = -log(softmax(predicted-logits))|correct-response \quad (1)$$

During training, the model will make a predicted answer, and loss will be accumulated if the answers are wrong. After each batch, the loss is backpropagated through the various network layers, and the model parameters are updated to minimize this loss. The loss and generated graphs can be found in Figure A1 and A2.

To train the floorplan generation model, we iterate through the dataset in batches, following a typical training process of GAN models by iteratively training the discriminator, and then the generator, each per batch. Training the discriminator involves generating a set of room masks, and passing these into the discriminator to get a "fake validity" score (binary response, real or fake), then passing in the corresponding real masks to get a "real validity score". These are summed with fake scores negated, along with a gradient penalty term. This loss is then used to backpropagate and update weights. Training the generator then proceeds by the generator producing masks, the discriminator scoring them, and any predicted as fake are counted up as the loss. Additionally, to train the generator to not change the conditioned masks, an L1 loss between the conditioned and generated masks is added to the discriminator loss. The detailed description of the loss function can be found in (Nauata et al., 2021, 2020). This loss is then backpropagated over the generator and weights are updated (Figure A3).

Evaluation

In this section, the evaluation methods are discussed at different points in the pipeline.

The validity of the generated layout graph is evaluated based on compliance with user input and basic design rules. It should be noted that the quality of the generated layout should be evaluated from a more comprehensive architectural design perspective and with potential human expert evaluation for benchmarking against other models, which will be future works and will be discussed in the next chapter. The validity evaluation criteria for the current research are as follows:

R1. the user input constraints are all fully met.

R2. all rooms have at least one door.

R3. exterior walls connect to two other walls and one room, which ensures no solitary walls exist.

R4. each room connects to at least one other room (or wall), which ensures no solitary rooms exist.

R5. each room has outgoing room adjacencies that cover at least two cardinal directions. This attempts to ensure that a room is bounded in all directions. Ground truth homes show that 99.97% of homes meet this criteria.

Table 1: Evaluation Validity Results for DGMG, 10x100 Graph Runs

	R1	R2	R3	R4	R5
Mean	0.13	0	0.061	0.091	0.337
STD	0.126	0	0.167	0.201	0.192

Table 1 shows the ratio of generated home layout graphs that fail each of the validity criteria. These results come from generating 100 layout graphs each from ten different user-input files, with results averaged over the ten runs. Finally, of the 1000 total graphs generated, they are valid 54.1% of the time with a standard deviation of 25.5% between the ten runs. It should be noted that the failure rate to meet R5 is significantly higher, which implies that the graph-representative model finds it more challenging to capture the directional relationships among rooms. It will be discussed in the next section.

The floorplan generation model is evaluated using the Fre´chet Inception Distance (FID). FID is a metric for image generators that evaluates the realism of the generated images by comparing them to a set of real, given images (Heusel et al., 2017). In our evaluation, the FID is used to assess the quality of the floorplans generated by the model using the floorplans in the LIFULL database.

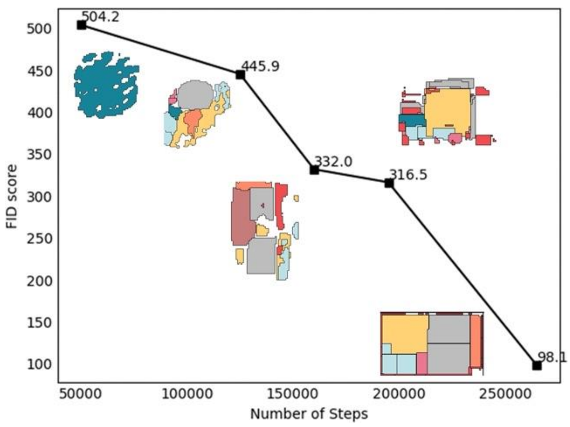

Figure 5 FID Score for HHGPP

Our FID score, Figure 5, is calculated after roughly every 50000 training steps. As the model learned, the floorplan generation model decreased the FID score from 504.2 to a final score of 98.1, indicating more realistic generated images. The score of 98.1 indicates a high similarity between the two distributions of real and generated images. Given enough computing power and training steps, the results could be further improved.

Discussion

We set out to show that housing design assisted by interactive AI based on graph representation is possible. Through the design of the envisioned user interface, review of the workflow, and evaluation of the supporting AI models, we have shown that architects have a new tool at their disposal to generate both home layout graphs and corresponding floorplans pertaining to their needs at higher efficiency. Currently, only a text-based interface is available for users. More advanced graphical interfaces could be developed and embedded into domain applications (e.g., CAD and BIM) based on the graph-based approach.

Both our augmented DGMG framework is a sufficiently capable architecture to learn to generate valid layout graphs that respect the user's input constraints, and the graph-constraint RaGAN architecture present in our HHGPP model is sufficient to learn to translate layout graphs into floorplans that maintain the constraints. This is important because it shows that the user input is not too complex to be learned by generative models in general.

However, the prediction of edge direction in the layout generation model is still imperfect. When the model adds a new node and a new edge from that node, it must then decide in what direction the connection will point. It is important to avoid contradictory constraints. The graph generation model still finds it hard to capture and fulfill all the hard constraints through learning. The reasons for the imperfection can be representation-related, model-related, or training-related. We believe the training process is adequately done considering the loss has dropped to a reasonably low level in different training parameters. The graph representation of the floorplan is quite complex in our current approach, which contains different types of edges and nodes with different attributes and semantic meanings. The tradeoff here is that more expressive graph representation of the housing designs would leave us more possibilities in the interactive design process and in combining computational design approaches. But it could also be more challenging for the models to capture the complex semantic information in the representation of housing designs since the generative models are mostly developed for applications with simple representations and big data (e.g., predictions of proteins or monocular structures).

To tackle this challenge, we will test different graph generation models (e.g., GraphRNN) to potentially identify the one with more expressive power. We would also try other graph representations for the layout to help the model better capture the embedded semantic and spatial relationships. In the meantime, the graph representation enables us to fix the generated layout through hardcoded rules. Also, different computational design methods can be implemented as complementary approach to the generative design by optimizing the results.

Another interesting finding is that small errors in generated layout graphs could result in noticeable contradictions in the corresponding generated floorplans. Even though the graph-based generative housing design pipelines allow more user interaction and control in every intermediate step, it could result in higher propagated error compared with end-to-end models.

Due to time and resource limitations, we only validate our models regarding compliance with user input and basic design rules, and the realism of floorplans. To bring our approach forward, we would scale up the testing and evaluation in two ways, including developing the qualitative matrices to evaluate the architectural quality of the generative housing design through a computational approach and developing a graphical user interface for larger-scale user evaluation. We would also benchmark the performance of our model against other state-of-the-art models in future research.

Since the graph representation is parametric, our graph-based approach could be compatible with various design tasks such as building equipment arrangement (Wang et al., 2019) and structural design (Zhao et al., 2024). It would be a promising direction to investigate how to integrate our graph-based method into a more generic design approach so as to ensure a more realistic and functional design solution.

Conclusions

In this paper, we presented an interactive AI framework for generative housing design, leveraging Graph Neural Networks (GNNs) and Deep Generative Models. Our approach, exemplified by the augmented DGMG framework for layout graph generation and Hetero-HouseGAN++ (HHGPP) for floorplan generation, demonstrates the viability of incorporating user constraints and requirements into the generative design process. Through an interactive interface, architects and stakeholders could actively participate in the design workflow, ensuring the production of feasible and user-centered housing design alternatives.

Moving forward, several avenues for improvement and exploration emerge. Firstly, the model is still insufficient in predicting the edge features and meeting all hard constraints in layout graph generation. We will test different models and representations for more expressive power in the learning for generative design. Future research could also look into computational methods as a complementary approach to fix and optimize the generated design alternatives based on graph representation. Moreover, user feedback and architectural quality metrics will be integrated into the evaluation process, providing a more comprehensive assessment of the generated designs.

This research would facilitate the housing design process through a collaborative and user-centered approach. The graph-based approach can also be integrated into more advanced design tasks (e.g., generative design of modular buildings based on BIM components library) due to its interoperability with the parametric data (e.g., IFC and IFCOWL), which would greatly facilitate the complex design process by harnessing the power of learning-based models and computational design approach. Despite only text-based interface is available for users currently, more advanced graphical interface could be further developed and easily embedded into domain applications (e.g., CAD and BIM) to facilitate the real-world design process.

DEVELOPMENT OF A DIGITAL TWIN-BASED SIMULATION SYSTEM AND A NOVEL SYNTHETIC VIDEO DATASET FOR ENHANCING COMPUTER VISION IN CONSTRUCTION SITE SAFETY

Zhengyu Wu, Yuxiang Feng, Yiannis Demiris, Panagiotis Angeloudis
Imperial College London, London, United Kingdom

Abstract

In this work, we introduce a novel construction simulation system and the first photo-realistic synthetic video dataset for the construction industry, named ConSynth. The system simulates vehicle dynamics, worker behaviours, and various environmental conditions (Figure 1), generating a dataset of 200 video sequences and 24,000 images with automated labels. Our experiments have shown that models trained on ConSynth achieve robust detection with less reliance on real-world data, indicating enhanced diversity, improved performance in underrepresented scenarios, and substantial generalisability. Our work promises significant advancements in construction safety monitoring through computer vision.

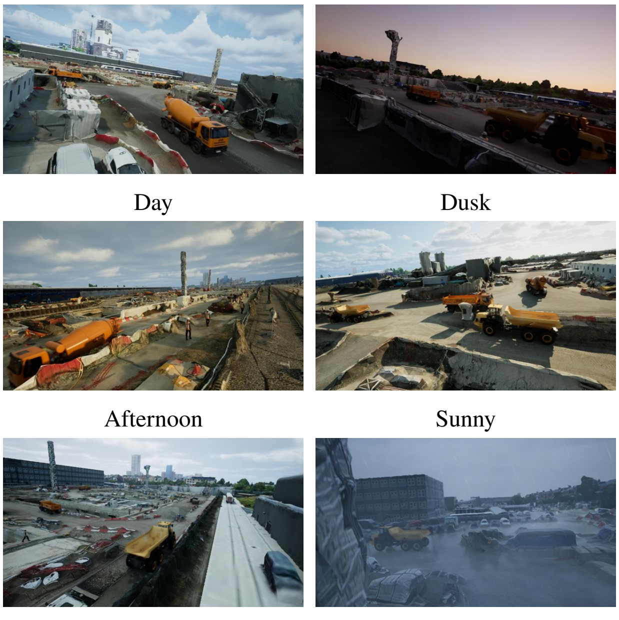

Figure 1: ConSynth contains video sequences initialised and rendered with different domain parameters

Introduction

Background

Construction sites are inherently hazardous. With the increasing application of deep learning techniques in safety monitoring on construction sites, accurate detection of construction equipment and workers has grown in importance. However, a significant barrier to this progression is the limited availability of labelled data, such as images or video frames, where each object (e.g. construction equipment or workers) is identified and annotated with a bounding box and a category. Currently, the two largest public datasets in this domain are the Detecting Moving Objects in Construction Sites (MOCS) dataset (Xuehui et al., 2021) and the Alberta Construction Image Dataset (ACID) (Xiao and Kang, 2021). Although models trained on such datasets have demonstrated the ability to effectively detect a variety of construction equipment or workers, a notable 'domain gap' often exists in their applications on real construction sites. This 'domain gap', a common issue in deep learning, signifies the discrepancies in sample distributions between the data that models are being trained on and the data in real-world applications. One common solution is to collect and annotate extra data from target construction sites and fine-tune the models. However, the manual annotation is time-consuming and error-prone, introducing noise and potential privacy concerns. Furthermore, the current focus of construction site datasets predominantly lies in 2D object detection, tracking, and instance segmentation. Other critical perception tasks witnessed in autonomous driving research, such as depth estimation or 3D object detection, remain largely unexplored in construction sites. This is mainly constrained by the significantly increased data collection and annotation cost associated with these tasks. To tackle these challenges, exploring synthetic datasets has emerged as a promising and vital research direction.

Research gaps

While synthetic construction datasets provide significant potential, investigations in current literature have revealed several limitations. One common method involves rendering 3D models of construction equipment or personnel and superimposing them onto backgrounds of construction sites, known as the crop and paste method (Lee et al., 2022). However, the generated images lack realism due to inconsistencies in camera perspective and lighting with the background images. Alternative methods attempt to craft a construction site manually using 3d modelling software and then render the models of construction objects within it (Soltani et al., 2016; Neuhausen et al., 2020; Lee et al., 2023). Yet, hand-crafting scenes fail to capture the details and complexity of real-world sites. Moreover, manual creation is often limited to specific research contexts and is difficult to adapt to general construction projects. Consequently, models trained on these synthetic datasets tend to be constrained by substantial domain gaps, undermining their performance in actual application scenarios. In the field of autonomous driving, strategies such as transfer learning, domain randomisation, and domain adaptation are typically employed to bridge this gap. However, their application in construction site monitoring is still rare. Lastly, most datasets for the construction industry contain only images. These discontinuous images, sampled at different intervals, restrict the extraction of spatio-temporal features of the scene.

Contributions

The contributions of this paper are two-fold. First, we propose a digital twin-based simulator that simulates realistic vehicle dynamics and worker behaviours. The simulator also adapts domain randomisation with the weather and lighting parameters to minimise domain gaps between reality and simulation. Second, our proposed synthetic dataset, 'ConSynth', is the first synthetic video dataset in the construction industry with the aim to broaden the scope of task applicability. This novel dataset provides continuous image sequences with precise labels for traditional computer vision tasks, such as 2D and 3D object detection, tracking, and instance segmentation, and enables additional tasks such as depth estimation, action recognition and behavioural analysis. Our research showcases that combining photo-realistic synthetic and real-world data significantly improves model robustness and accuracy in construction site scenarios, effectively reducing the reliance on extensive real-world data collection and manual annotation. Our findings highlight the potential of synthetic data in enhancing model robustness, offering a solution for deploying computer vision in dynamic and challenging construction environments.

Related Works

In this section, we review existing research on developing datasets for deep learning applications. Initially, it outlines the current state of real-world datasets in autonomous driving, underscoring the emergence of synthetic datasets as a promising alternative to manual data collection. Following this, the section discusses the development of synthetic datasets in the construction industry.

Real-world Datasets

Deep learning models are highly data-dependent. Over the past decade, the rapid advancement in autonomous driving research has been significantly fuelled by vast amounts of data from real-world sensors (Feng et al., 2021). The collaboration between the industrial and academic sectors has led to the annotation and release of several mature datasets, such as KITTI (Geiger et al., 2013), nuScenes (Caesar et al., 2019), and Argoverse (Chang et al., 2019). These datasets have catalysed the progress in autonomous driving research by supporting various tasks, notably 2D/3D detection and tracking, depth estimation, and stereo vision.

In the construction industry, researchers are also developing datasets to train deep-learning models. Xuehui et al. (2021) released the first large-scale construction site dataset, MOCS, which offers around 42,000 images covering 13 common construction equipment categories, supporting 2D object detection and segmentation. Similarly, the ACID dataset (Xiao and Kang, 2021) provides 10,000 images covering ten types of construction equipment, targeted primarily for 2D object detection. They have paved the way for deploying 2D detectors like Faster-RCNN, YOLO, and Mask RCNN in the industrial sector. However, compared with the autonomous driving sector, datasets for the construction industry are still relatively scarce and limited to a narrow range of tasks.

Synthetic Datasets in Autonomous Driving

The development of synthetic datasets is emerging as a solution to the challenges of data collection. In autonomous driving, a pioneering example is the dataset introduced by Richter et al. (2016), which utilises highly realistic imagery from commercial video games and intricate simulations of interactions between pedestrians and vehicles to provide pixel-level semantic segmentation labels. Combining synthetic with real datasets such as KITTI (Geiger et al., 2013) has enhanced model training accuracy while reducing reliance on expensive manual annotation of real-world data. Similarly, SYNTHIA (Ros et al., 2016) generates semantic segmentation labels for driving scenarios using a simulator built with the Unity game engine. Experiments in this work have demonstrated that models trained on SYNTHIA and fine-tuned with real-world datasets show improved accuracy. VIPER (Richter et al., 2017) extends the scope by providing annotations for multiple tasks, including 2D/3D object detection, multi-object tracking, and optical flow estimation. Additionally, it includes data from five different environmental conditions and diverse urban landscapes. AIODrive dataset (Weng et al., 2020) provides point cloud data from LiDAR sensors in varying densities, in addition to complete annotations for object detection, and covers diverse scenarios and weather conditions. CarlaScenes (Kloukiniotis et al., 2022) provides a practical solution for annotating real-world scene data for multiple challenging scenarios using the CARLA simulator (Dosovitskiy et al., 2017). SHIFT (Sun et al., 2022), another dataset based on the CARLA simulator (Dosovitskiy et al., 2017), encompasses the 13 most significant perception tasks in the domain of autonomous driving. The continuous domain shifts, a distinctive feature of SHIFT, enable the researchers to evaluate the 'domain gaps' and benchmark domain transfer algorithms.

Synthetic Datasets in Construction

To date, the synthetic approach has not been thoroughly explored in the research domain of construction. Most studies used synthetic datasets for specific tasks where manual data annotation is challenging. For example, stud-

(a) Crop and paste (Lee et al., 2022) (b) 3D rendering (Barrera-Animas and Delgado, 2023) (c) Digital twin-based simulation **(Ours)**

ies by Soltani et al. (2016); Lee et al. (2022) rendered 3D models of excavators in various poses and superimposed them onto diverse construction site backgrounds to enhance the accuracy of detecting excavators in images, particularly smaller objects (Figure 2a). Similarly, Assadzadeh et al. (2022) synthesised images of excavators for training object detection models and extended the research to quantitatively analyse the role of domain randomisation in bridging the gap between synthetic and real-world images. Neuhausen et al. (2020) used manually created scenes and pre-captured motion animations to render 3D worker models under varying lighting and weather conditions, aiming to improve the tracking accuracy of construction workers. Additionally, Lee et al. (2023) employed a game engine to create a synthetic dataset to enhance the detection precision of workers' small personal protective equipment for safety monitoring. Barrera-Animas and Delgado (2023) expanded the research scope by covering multiple equipment categories, combining a series of 3D models, and rendering them under diverse lighting scenarios. However, the effectiveness of these datasets is still in question due to their severe lack of photorealism. Results indicated that models trained on these datasets performed poorly when tested on real-world data Barrera-Animas and Delgado (2023). Despite these limitations, these pioneering datasets have laid the groundwork for developing more complex, multi-task synthetic datasets in construction safety research.

Developing Construction Simulation System and Synthetic Video Dataset

In this paper, we created a novel construction simulation system to simulate the behaviours of various agents under different lighting and weather conditions. Within the system, we generated a novel synthetic video dataset, ConSynth, featuring annotations for various tasks. The overall process can be found in Figure 3.

Generation of the Digital Twin

As discussed in the previous section, existing methods generated images with a lack of realism. In this work, we propose using a digital twin model to preserve the details of actual sites. First, we selected an actual construction site in northwest London, UK, as the case study area. Then, a UAV was scheduled to follow a pre-designed route over the site, capturing images at a frequency of once per week. We estimated the three-dimensional structure using the Structure from Motion (SfM) algorithms based on images and the known camera parameters during capture. This process involved the use of Bentley ContextCapture software.

Although our digital twin model was regularly updated to reflect the continuous changes at the construction site, it only includes the case study site and a small surrounding area. A large proportion of the background was missing when we used cameras within the simulator to capture images at a flat angle. Tremblay et al. (2018) found that diversity in the background of synthetic datasets is crucial, as it encourages the model to learn the most representative features of the target objects, thereby distinguishing them from the complicated background. Expanding the UAV capturing area would be computationally costly and time-consuming. As an alternative, we integrated the 3D model from Google Earth to fill the distant scenery. After localising the scanned model in a geographic coordinate system, we removed the scanned region from Google's 3D model and overlaid our model. This approach ensures the most recent scanned model is used for the construction site area, while Google Earth, with less frequent changes, is used as the distant scenery.

Simulation of Site Logistics

The next step involves simulating the agents, such as the construction equipment and workers, with realistic behaviours. This simulation comprises three parts: (1) site road configuration, (2) generation of site agents, and (3) movement of each agent.

To accurately represent the site road configuration, our approach involves creating a vector map in alignment with the site's logistic plan (Figure 5). We utilised the map handling framework Lanelet2 (Poggenhans et al., 2018), a tool prevalent in the autonomous driving sector for map reading and trajectory planning. These vector maps, essential

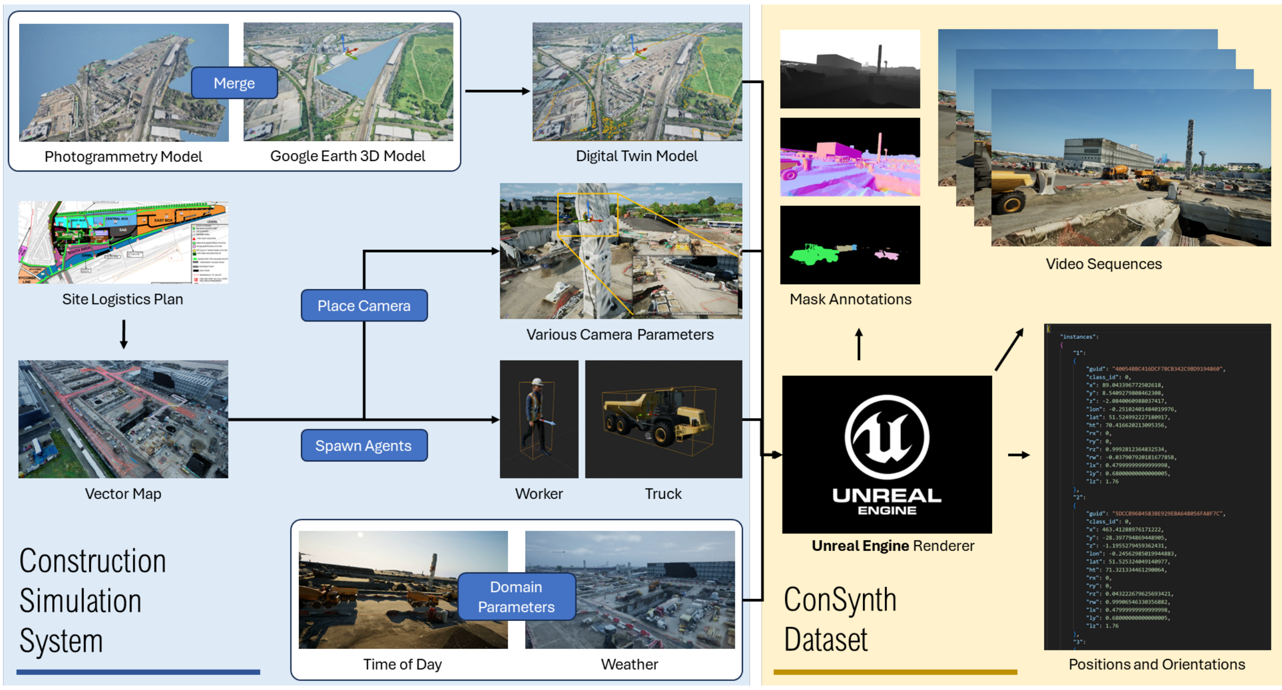

Figure 3: Diagram of the overall process to generate the synthetic video dataset within the construction simulation system

for autonomous driving, offer detailed vector-based road information, including lanes, crossings, and intersections. Leveraging Lanelet2, we implemented the behavioural logic for agent movements. For instance, trucks are programmed to travel on vehicle lanes and navigate through intersections, while workers are set to follow pedestrian pathways and crossings. These movements are governed by the underlying logic provided by the Lanelet2 framework to ensure a more realistic simulation.

We then developed a rule-based system for generating agents based on the vector map. Initially, we tagged haul roads and one-way roads with a 'vehicle' tag and intersections with both 'vehicle' and 'intersection' tags. Pedestrian footways and crossings received a 'pedestrian' tag. The generation follows these rules:

1. Vehicles, such as dump trucks and mixer trucks, are only generated on lanes tagged with 'vehicle' and not 'intersection', with a minimum spacing of $S_{min,veh}$ and a maximum of N_{veh} vehicles on the map;
2. Pedestrians are generated only on lanes tagged 'pedestrian', with a minimum spacing of $S_{min,ped}$ and a maximum of N_{ped} pedestrians on the map;
3. For candidate lanes tagged 'pedestrian', we check if the lane intersects with any lane tagged with 'vehicle', identifying it as a pedestrian crossing.
4. For each lane tagged 'intersection', we use the $k-NN$ algorithm to cluster lanes belonging to the same intersection and generate a special agent as the controller: the intersection agent.

All agent movements are based on their respective lanes. Vehicles move on lanes tagged with 'vehicle', randomly choosing a connected lane at the end of their current lane. If the upcoming lane belongs to an intersection, the corresponding intersection agent will take over the control when a vehicle approaches the stop line. Similarly, pedestrians move only on pedestrian-tagged lanes and randomly select the next lane. If a pedestrian crossing is found to be chosen as the next lane, the agents check if the crossing holds a 'walkable' tag. If the tag is absent, they wait at the end of the crossing. Otherwise, they continue to walk through the crossing. Each intersection agent, simulating a traffic light, sequentially checks its managed lanes with a 'vehicle' tag. For each lane, if a vehicle is found waiting at a stop line, the agent allows it to pass through the intersection and assigns it to a lane at the other end. After a round of checks, a 'walkable' tag is added to all managed pedestrian crossings for a duration of t, allowing all pedestrian agents to cross the vehicle lanes freely.

Domain Randomisation

One major drawback of the current public datasets in construction is that most samples were collected under good illumination conditions. Consequently, models trained on these datasets struggle to handle adverse weather and lighting conditions effectively. To improve model robustness under varying conditions, such as night and rainy and foggy weather, we propose the use of domain randomisation. Specifically, we randomised the weather and time of day in the game engine to create scenes with diverse appearances (Table 1).

Camera Placement

We developed an algorithm for camera placement to ensure that they capture agent movements in the camera view rather than just the background. To begin with, we ran-

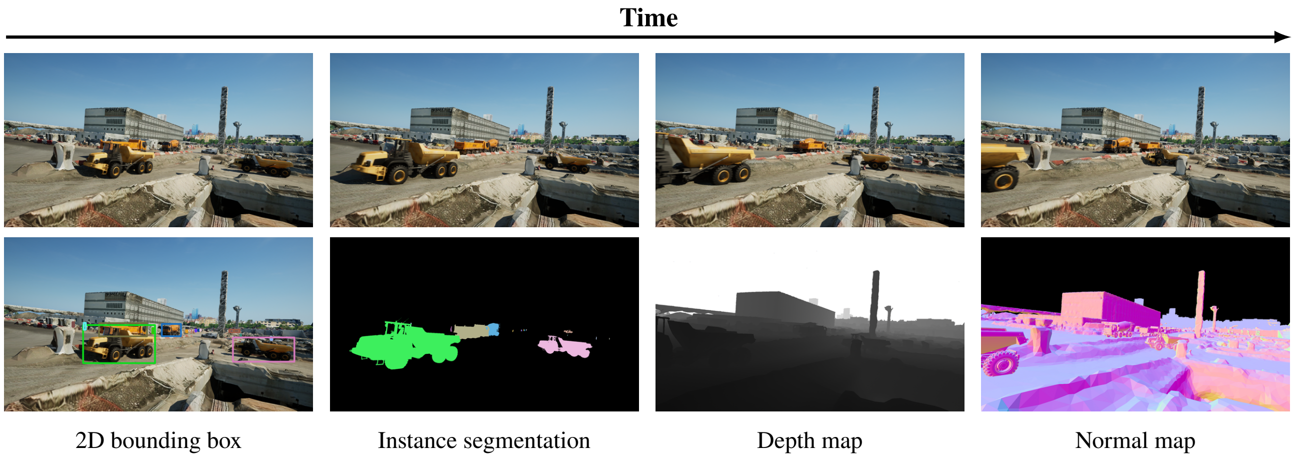

Figure 4: ConSynth provides continuous image sequences with precise labels of 2D bounding boxes, instance segmentation, depth map and normal map. The dataset supports both image-based and video-based computer vision tasks including object detection and tracking, instance segmentation, depth estimation, action recognition and behaviour analysis.

domly selected a point on one of the lanes from the vector map. Then, a centre was set between z_{min} and z_{max} above this point, generating a semi-sphere with a radius between r_{min} and r_{max}. A point on the surface of this semi-sphere was chosen randomly as the initial camera position. We then performed ray tracing from the centre to this point to avoid obstructions and repeated the selection process until the view was unobstructed. A camera was then positioned at this point, oriented towards the centre. Finally, we randomised the camera's intrinsic and extrinsic parameters, including the field of view and orientation, to ensure our dataset covers a variety of perspectives.

Automated Annotation

We leveraged Unreal Engine 5 for rendering photo-realistic RGB images and mask annotations. In addition, we developed a C++-based tool for automated annotation that, for each rendered frame, collects 3D transformations of all agents in the scene, including relative coordinates (x, y, z), world coordinates $(latitude, longitude, height)$, rotation angles (r_y), and dimensions of 3D bounding boxes (l_x, l_y, l_z). It also gathers camera intrinsic and extrinsic parameters, exporting them along with the agent transformations. The segmentation annotations are initially exported as mask images, where a unique colour represents each agent. Following the generation, we utilised OpenCV (Bradski, 2000), a public computer vision library for image processing, to identify these colours and extract polygon-based segmentation data. Finally, the tool calculates the smallest enclosing rectangle from the segmentation as the 2D bounding box for each agent. The automated annotation system, illustrated in Figure 4, is of significance in reducing the time and resources required for the generation of extensive, high-quality and accurate labelled datasets.

Dataset Statistics

Our ConSynth dataset encompasses 200 video sequences, each uniquely produced within the digital twin environment using randomly varied parameters and captured from different locations (see Figure 1). Every sequence consists of 120 frames, recorded at 12 frames per second. Within the dataset, we focus on three primary categories: workers, dump trucks, and mixer trucks. The most populous category is the workers, with $237,215$ instances, which is twice the number of dump truck instances. Mixer trucks, being the least common type, have $31,800$ instances. Figure 6 details the distribution across these categories. Notably, the dataset totals 24,000 images, which results in an average of around 15 instances per image. This density of instances is vital for training robust models, offering a diverse and comprehensive range of data for each category.

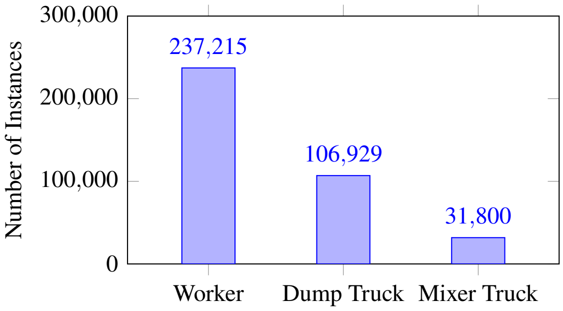

Figure 6: Distribution of different categories (workers, dump trucks, and mixer trucks) in the ConSynth dataset.

The images generated in the ConSynth dataset have a resolution of 1920×1080 pixels. We referred to the standards for object sizes set by the COCO dataset to analyse the distribution of objects of various sizes. According to COCO, in images of 640×480 resolution, objects with an area less than 32×32 pixels are classified as small objects, and those less than 96×96 pixels as medium objects, with the remainder being large objects. We scaled this standard proportionally to match our resolution, resulting in the distribution of small, medium, and large objects in our dataset being 63%, 24%, and 13%, respectively.
This significant presence of small objects in the dataset is a critical feature, as it aligns with real-world scenarios where computer vision models need to identify small yet significant objects on construction sites, commonly workers. To empirically evaluate the effectiveness of the ConSynth dataset in addressing real-world challenges, the next section will present a series of experiments. These experiments are designed to test the dataset's performance in enhancing object detection in real-world construction sites, particularly of small objects.

Experiments

In this section, we explore the effectiveness of using the synthetic ConSynth dataset in the field of object detection, with three focuses: enhancing real data with ConSynth to improve model performance, reducing the reliance on real data by leveraging ConSynth, and evaluating the performance of ConSynth in a case-study construction site.

Training and Validation Setup

We employed the YOLOv8 model, a commonly used open-source one-stage object detector known for its anchor-free design, fast speed, and high accuracy. We used two datasets for training: a real dataset and a synthetic dataset (i.e. ConSynth). The real dataset combines the largest available construction site datasets, MOCS (Xuehui et al., 2021) and ACID (Xiao and Kang, 2021). For ACID, we split it into 80% for training and 20% for validation. The 80% from ACID was merged with the MOCS training set

(a) Real (MOCS + ACID) (b) Synthetic (ConSynth) (c) Case study

Figure 7: Examples from the experiment datasets. ConSynth dataset provides images similar to images from the case study dataset but targets adverse lighting and weather conditions.

to form our training dataset, and the 20% was combined with the MOCS validation set for our validation dataset. The final composition of the real dataset included 24,233 images in the training set and 5,219 images in the validation set. For the ConSynth dataset, encompassing 24,000 images, we similarly allocated 80% (19,200 images) for training and 20% (4,800 images) for validation.
We also created another dataset, the case study dataset, for validation independent from any of the training datasets. We collected 500,000 images from real cameras at the case study construction site, which covers various construction equipment, personnel, weather, and lighting conditions. From these, 10,000 images were randomly selected following a normal distribution. Using a MobileNetv2 model (Sandler et al., 2019) trained with the ImageNet dataset (Deng et al., 2009), we computed the visual embeddings for each image and selected the 100 most unique images based on these embeddings. These images were then manually annotated and reviewed by experienced engineers. Examples from these datasets can be seen in Figure 7.
The training was conducted on four RTX 4090 24G GPUs with a batch size of 16 over 100 epochs. The base learning rate was set to $lr_0 = 0.002$, employing an SGD optimiser with a learning rate factor of $lr_f = 0.01$. The size of the input image was maintained at 640×640. After the training, a key performance metric, mean Average Precision (mAP), was employed to evaluate each model's performance. The mAP is defined as the percentage of correct predictions, algebraically represented as:

$$mAP = \frac{TP}{TP + FP} \quad (1)$$

where TP denotes the number of true positives, FP represents the number of false positives.

Enhancing Model Performance with Synthetic Data

This section explores the impact of using the synthetic dataset ConSynth on model performance in three scenarios: (1) training separately on real and synthetic train sets and validating on their respective validation sets; (2) training separately on real and synthetic train sets and validating on the other validation set; (3) training on combined train sets and validating on combined validation sets. The results are detailed in Table 2.
Our research found that models trained on both the real and synthetic datasets performed well on their respective validation sets, indicating the effectiveness and domain-

Table 2: Performance Comparison of Models. Notably, models trained solely on the Consynth dataset improved the accuracy of detecting dump trucks by 20%. *Models trained on the combined datasets improved the accuracy of detecting dump trucks by* 40% *and all classes by* 13%.

Train	Validation	Worker	Dump Truck	Mixer Truck	All Classes
Real	Real	62.6	67.2	78.3	69.3
Synthetic	Synthetic	31.3	69.8	68.1	56.4
Real	Synthetic	6.1	11.4	10.2	9.3
Synthetic	Real	9.0	3.8	4.3	5.7
Real + Synthetic	Real	62.8	65.1	75.6	67.8
Real + Synthetic	Synthetic	25.9	64.7	61.9	50.8
Real	Case Study	10.4	6.4	13.1	9.9
Synthetic	Case Study	1.9	7.7 (+1.3)	3.1	4.2
Real + Synthetic	Case Study	**10.5** (+0.1)	**9.0** (+2.6)	**14.0** (+0.9)	**11.2** (+1.3)

specific robustness of the datasets. However, the performance of these models on the opposite validation sets was poorer. This performance drop is primarily attributable to the domain gap between the real and synthetic datasets. Despite our efforts to minimise this gap through photo-realistic rendering and domain randomisation during the data generation, a discernible difference remains. Another reason for the performance discrepancy is that the ConSynth dataset more closely resembles the data collected from the specific construction site used in our case study. The distribution of object types, appearances, and sizes in ConSynth differ from those in the public construction datasets, creating an inherent domain gap that will be further analysed in subsequent sections.

We also combined the real and synthetic datasets to bridge the gap between domains. Interestingly, the model trained on the combined dataset showed a slight decrease in performance metrics in each domain. However, this does not necessarily indicate a deterioration in model performance. Instead, it suggests that the model has adapted to data from multiple domains, leading to a more generalised model. This generalisation is a positive attribute, especially for practical applications in complex construction sites where conditions vary significantly.

To validate this generalisation, we evaluated all trained models on the dataset created and annotated from the case study construction site. As shown in Table 2, the model trained on the synthetic dataset has shown promising improvement in dump truck detection as the Mean Average Precision (*mAP*) improved by 20%. The model trained on the combined dataset outperformed the other two models in all aspects. Notably, the improvement in dump truck detection was significant, jumping from 6.4 to 9.0 by 40% while the *mAP* for all classes was improved by 13%. However, despite these improvements, all three models' *mAP* was generally low. This is attributed to the high resolution of site cameras and the distance of these cameras from the targets, resulting in small object sizes in the images. The down-sampling of high-resolution images from 1920×1080 pixels to 640×360 pixels for convolution operations in the backbone likely leads to a loss of critical features, intensifying the challenge of detecting small objects. Yet, with the presence of a large number of small objects in the dataset, the ConSynth dataset helps enhance the model's performance in detecting small objects on construction sites.

Finally, we conducted a quantitative analysis of video footage from our case study construction site to investigate how the ConSynth dataset enhances model performance in specific construction scenarios. The results, depicted in Figure 8, compare the performance of models: (a) trained solely on the real dataset and (b) trained exclusively on the ConSynth dataset, with the latter having no exposure to real dataset images. The findings demonstrate that the model can effectively learn features of different classes from the ConSynth dataset and make accurate predictions, even without real data. In this comparison, the model trained with ConSynth data notably reduced false positives in the worker category and improved the detection of overlapping dump trucks, thereby reducing false negatives. However, it struggled to detect workers partially obscured by railings, a limitation likely due to a lack of representative samples in the synthetic dataset. This issue can be mitigated by combining the ConSynth dataset with real data. Overall, the ConSynth dataset showed promising results, effectively reducing reliance on real data and demonstrating significant potential.

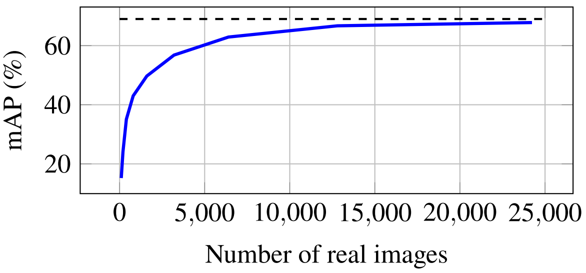
(a) Model trained on real dataset

(b) Model trained on ConSynth dataset

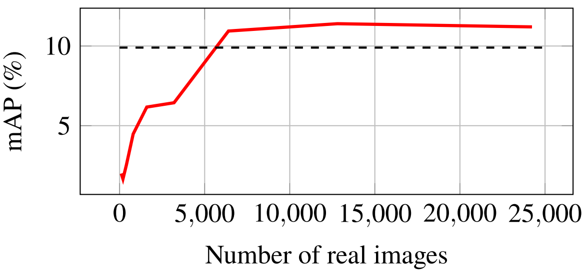
Figure 8: Models trained solely on the ConSynth dataset yield better accuracy in detecting dump trucks and comparable accuracy in detecting workers.

Relieving the Burden of Manual Labelling

In this section, we primarily explore how synthetic datasets can alleviate the reliance on real-world data. We randomly selected k samples from a real training set comprising 24,233 images. The sampling followed a normal distribution, where $k \in [100, 200, 400, 800, 1600, 3200, 6400, 12800]$. We combined the selected samples with the entire synthetic dataset to form eight distinct training sets. These datasets were then used for training with the same hyper-parameters from the previous section.



(a) Model performance (mAP) on the real dataset



(b) Model performance (*mAP*) on the case study dataset

Figure 9: Comparison of model performance in response to varying proportions of real data in training. Reliance on real data can be significantly reduced with synthetic data, especially in underrepresented scenarios targeted by synthetic data.

Validation was performed on the real dataset's validation set, and the results are depicted in Figure 9a as a solid blue line. The dashed line represents the baseline ($mAP = 69.0\%$), which is the performance using only the real dataset for training and validation. The graph indicates that as the proportion of real data in the mixed dataset increases, the model's performance on the real training set improves, signifying the learning of domain-specific features. While the mixed dataset did not surpass the baseline, it is notable that when the real data was reduced by 47.2% (from 24,233 to 12,800), the model's performance remained close, with *mAP*s of 67.8 and 66.7, respectively. Further reduction of real data to 26.4% (from $24,233$ to $6,400$) still resulted in a significant *mAP* (62.9%). This demonstrates that mixing synthetic with real data for training substantially decreases the dependency on real data.

We also verified the performance of models trained on the mixed datasets using data collected from a case study construction site, as shown in Figure 9b. The dashed line represents the performance of models trained on real data for this case study dataset. The trend observed was similar to the previous experiment, where reducing the real data in the dataset by approximately 75% still yielded comparable performance. Notably, the model exceeded the baseline performance on this dataset, indicating the use of synthetic data in improving the model's robustness. This can be attributed to using a digital twin model closely resembling the actual construction site in the synthetic data generation process, which aids in improving the model's performance in underrepresented site scenarios.

Conclusions

In this work, we have introduced a digital twin-based simulation system for generating synthetic datasets for construction site scenarios. Our method outperforms previous approaches by producing photo-realistic images to enhance the overall model performance in various construction scenarios. Moreover, we have introduced ConSynth, a novel synthetic dataset. The dataset is the first video dataset in construction that supports common perception tasks and provides valuable annotations for potential tasks which have not been extensively applied in the industry.

Currently, ConSynth includes three different categories of construction personnel equipment. Future work could expand the dataset's scope by incorporating additional construction equipment, such as excavators, loaders, and cranes, into the simulation. This expansion would further enhance the dataset's applicability and relevance to real-world construction scenarios. In addition, the models evaluated in this study exhibit a relatively low mean Average Precision (mAP) for detecting small objects in high-resolution images. Future work should conduct extensive experiments to explore improvements in mAP, potentially through methods like data augmentation and advanced algorithms, including the Slicing Aided Hyper Inference (SAHI) (Akyon et al., 2022).

We anticipate that our approach will not only improve the accuracy and robustness of computer vision applications in dynamic and challenging construction environments but also significantly reduce the costs associated with data collection and labelling. With a richer dataset, computer vision models are expected to not only accurately locate key targets and detect potential hazards but also contribute to the proactive enhancement of safety monitoring on construction sites, thereby mitigating risk and ensuring the well-being of personnel. In light of this, the ConSynth dataset will be made available at `https://github.com/tsl-imperial/ConSynth`.

Acknowledgments

The authors wish to extend their sincere gratitude to their industry collaborator, Balfour Beatty VINCI SYSTRA Joint Venture (BBVS JV), for their invaluable support and collaboration in this research. The provision of funding and access to the case study construction site for data collection were integral to the success of this study. Their contributions have been fundamental in advancing the research presented in this paper.

Abstract

Digital twin in the construction phase—termed Construction Digital Twin (CDT)—faces more significant challenges than in other phases, such as operation or maintained phase, due to the dynamic and evolving nature of construction sites and their broad spectrum of applications. To enhance our understanding of the CDT domain, it is crucial to clearly define it, establish a detailed taxonomy of its current applications and enabling technologies, and elucidate how attributes, data requirements, and technology choices within CDT vary across different construction applications. This objective remains unmet in existing literature, a gap this paper addresses through an approach combining systematic review, thematic coding, and conceptualization of CDT architecture comprising of five layers: sensing, communication, storage, analytics, and visualization. The study identifies seven major applications of CDT and maps them to the five architectural layers and their enabling technologies, providing insights into the suitability and prevalence of these technologies for specific applications of interest.

Introduction

Digital twin (DT) is an emerging and promising advancement that has the potential to transform the construction industry and drive its productivity (Boje *et al.*, 2020; Opoku *et al.*, 2021). DT is generally perceived as an up-to-date digital representation of a physical system and its functional properties leveraging data streaming from a wide range of data capturing and communication technologies (Sacks *et al.*, 2020). It can provide data-driven insights about the state and performance of an object or a process in real time thus enabling informed decision-making capabilities. DT generally has three main elements: the physical environment, its digital representation, and the streaming of data/feedback that connects the two, enabled by data sensing technologies, artificial intelligence functions, and high-speed networking (Sacks *et al.*, 2020).

Although DT is still regarded as a nascent concept within the construction industry, it has attracted substantial attention from researchers over the past five years investigating its applications during the different phases of built asset projects, with a particular focus on the design and operational phases (Opoku *et al.*, 2021). DT applications during the construction phase have been emerging recently and still require extensive research.

Hence, this paper aims to present a systematic approach to reviewing, mapping, and classifying the different applications of DT exclusively during the construction phase of built assets, namely Construction Digital Twin (CDT). Doing so provides transparency to readers on the most comprehensive state-of-the-art applications of DT and further supports its adoption during the construction phase. This paper also aims to thoroughly examine the different DT systems presented within the literature to give a generalized anatomy of DT architecture and the different technologies integrated within its identified layers. This will provide knowledge of the concepts, technologies, and processes required to replicate or build upon existing systems thus enhancing the scalability and adaptability of future-developed DTs.

Research Methodology

A systematic review was performed by following the reporting checklist of PRISMA to present a transparent, replicable, updateable, and comprehensive summary of previous studies related to CDT domain. Three databases were selected (i.e., Scopus, Web of Science, and Google Scholar) for carrying out the preliminary literature search. For Google Scholar, the search string included keywords of "Digital twin" and "Construction site" or "Construction Phase" and only results within the first 30 pages were included as results were not relevant anymore to the scope of this search. For Scopus and Web of Science, these keywords were expanded to form a broad search string presented in Table 1. The search, unrestricted by publication date up to July 2023, retrieved 504 DT publications from three databases, which were then systematically filtered using the inclusion and exclusion criteria detailed in Table 2. Figure 1 summarizes the literature search and selection procedure. The final set of 112 papers was examined to provide a thematic analysis that highlights the different applications of CDT and enabling technologies employed within each layer of a proposed conceptualized architecture.

Table 1. Scopus search string

(TITLE-ABS-KEY ("digital" OR "virtual" OR "cyber") AND TITLE-ABS-KEY ("twin*" OR "replica*" OR "shadow" OR "counterpart*") AND TITLE-ABS-KEY ("construction site*" OR "building site" OR "infrastructure site" OR "*project site*" OR "construction phase*" OR "building phase" OR "construction stage" OR "building stage" OR "engineering projects" OR "engineering site*" OR "construction operation*" OR "construction task*" OR "construction activity*" OR "building operation*" OR "building task*" OR "building activity*" OR "building project*" OR "construction management*"))

Table 2. *Inclusion and exclusion criteria for the literature search*

Inclusion criteria	Exclusion criteria
- Journal Articles - Conference papers - Review papers - Final publication stage - Any publication date - English language documents - Literature covering the scope of this research (i.e., DT for construction phase applications). - Literature that covers DT for the whole construction industry and includes sections related to the construction phase or construction management.	- Non-English language. - In press documents - Book chapters - Duplicate studies reported on research that had been previously published (e.g., a conference paper gets extended into a journal article or vice versa) - Studies that are irrelevant to DT concept - Research Studies from other industries (e.g., manufacturing, aerospace, oil & gas, naval, marine, aviation, urban/city planning, etc.) - Studies that are out of scope (e.g., DT implementations during other phases like the design, operational, or maintenance phases.

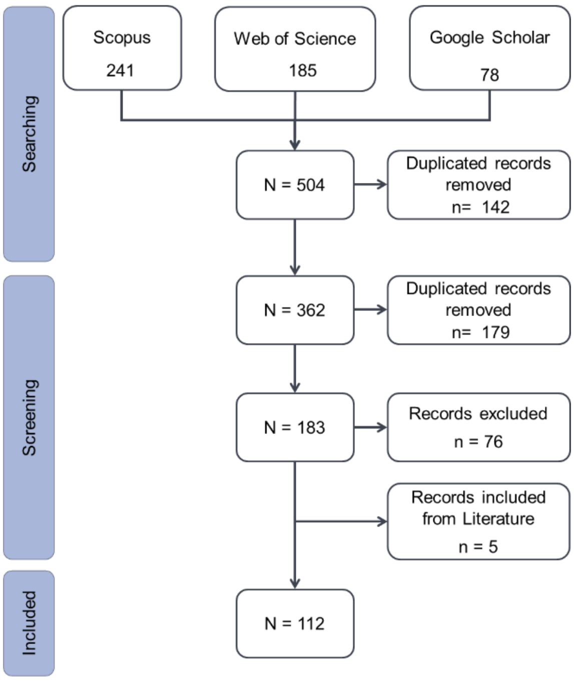

Figure 1. Study selection process based on PRISMA.

Taxonomy of CDT Applications

Seven major CDT applications and 17 sub applications emerged from the conducted thematic analysis. This includes 1- Safety and Risk Management (SRM), 2- Progress Monitoring and Control (PMC), 3- Data Integration and Management (DIM), 4- Construction Robotics and Automation (CRA), 5- Supply Chain and Logistics (SCL), 6- Quality Control and Assurance (QCA), 7- Sustainability and Circular Construction (SCC). Figure 3 demonstrates the distribution of these major applications within the literature, providing insights into the level of research corresponding to each application. For instance, "Safety and Risk Management" emerged as the most investigated area of CDT application while "Sustainability and Circular Construction" attracted the least research attention, thus offering a promising area of CDT for future research. Table 3 summarizes the seven CDT applications, their sub-implementations, and the corresponding key technologies and processes.

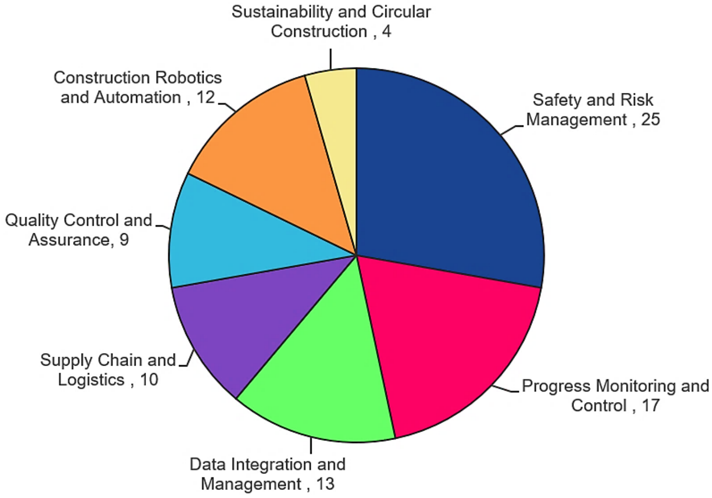

Figure 2. Distribution of the identified CDT applications across the reviewed studies (total number of 90).

CDT Architecture and Enabling Technologies

This section introduces a conceptualized architecture of CDT to better explore and categorize the different enabling technologies and processes integrated into a CDT to serve its intended application, (see Figure 3). The proposed architecture presents five distinct layers constructing a CDT: sensing, communication, storage, analytics, and visualization layer, their data interaction, and the feedback-decision making- loop mechanism. In this context, a "layer" denotes the logical combination of the hardware and/or software components sharing common functionality and purpose. Systematically, a "CDT architecture" is an enclosed combination of the required layers constructed to interact in a way that enables data collection, transmission, processing, and visualization to support informed decision making.

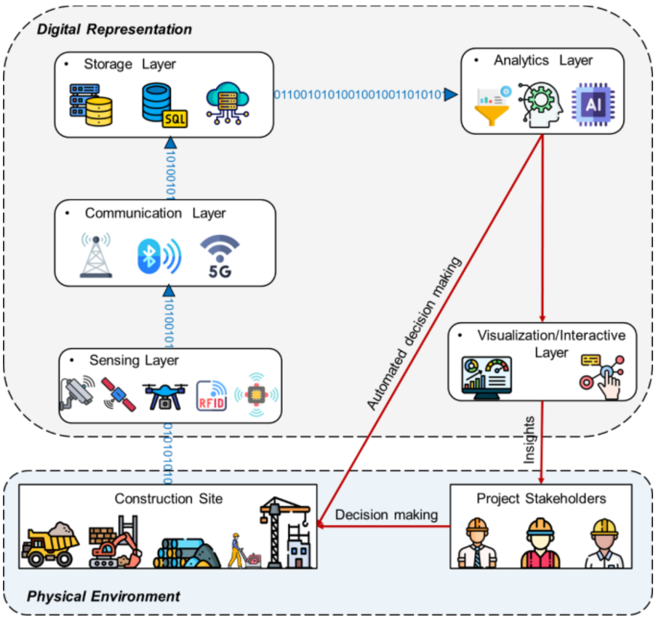

Figure 3. The proposed conceptualized CDT architecture

Table 3. A summary of the identified thematic applications of CDT and their corresponding technologies and processes

Application	Sub-application	Implementations Summary	Key technologies and processes	Reference
SRM	Workers' Health and Safety Management	Tracking workers' locations and issuing proactive warnings for trespassing hazardous zones; Monitoring Worker's physical health and posture; and Interactive site visualization for safety training.	RFID, LoRa, GPS, Insole pressure sensors, YOLOv4, Deep SORT, Deep learning, VR, MR headsets	(Lee and Lee, 2023; Osti et al., 2021; Wu et al., 2022; Zhang et al., 2023)
	Hazards Identification and Prevention	Identify and proactively prevent safety threats in a job site (e.g., tunnelling, crane operations, and drilling tasks).	Photogrammetry, kinematic sensors, spatial/orientation sensors, BIM, RFID, DNN, LSTM, XGBoost, BPNN, and AdaBoost.	(Jiang, Ding, et al., 2021; Kamari and Ham, 2022; Shariatfar et al., 2022; Zhao et al., 2022)
	Equipment Health Monitoring	Monitoring the operating status of construction equipment, mainly tower cranes, against mechanical and structural failure.	Mechanical and motion sensors, inclination and load sensors, RFID, IMU, Finite Element analysis (FEM), Multi Fidelity Surrogate model, Deep learning, LoRa, Visualization interface	(Jiang, Ding, et al., 2022; Lai et al., 2022; Li et al., 2021; Liu, Li, et al., 2022)
	Human-Machinery Interaction	Enhancing workers-machinery interactions on site to prevent accidents and fatalities in limited space. Earthwork is the main use case	Bluetooth Low Energy (BLE), Real-time location system (RTLS), Bayesian network, cameras, YOLOv5	(Assadzadeh et al., 2023; Huang et al., 2021; Kojima et al., 2020; Leonardo et al., 2020)
PMC	Productivity Estimation and Prediction	Equipment tracking for estimating and predicting productivity and utilization rates (i.e., mainly plant equipment). QCA	As-Built vs As-Designed Verification	Ensuring the geometric quality of as-built products by verifying them with as-designed models; common with prefabricated elements.	Laser scanning, LiDAR, photogrammetry, MR, AR, Scan-vs-BIM, Scan-to-BIM, CNN.	(Rausch and Haas, 2021; To et al., 2021; Tran et al., 2021)
	Regulatory Standards Compliance	Checking the quality of construction products and processes based on their compliance with relevant regulations and standards (e.g., concrete maturity properties and road compaction).	Piezoelectric sensor, Velocity sensor, BIM, Thermocouple sensor, FEM.	(Han et al., 2022; Kosse et al., 2022; Posada et al., 2022)
SCC	Embodied Carbon Monitoring	Estimating and monitoring the emission of embodied carbon dioxide during the construction process of a built asset.	QR code, UWB, IFC-based data schema, RFID, Accelerate sensor, BIM model, Wi-Fi	(Chen et al., 2021; Mao et al., 2018; Shen et al., 2022)
	Circular Construction	Facilitating the reuse and recycling of construction materials to reduce waste and enhance the efficiency of resource utilization	GPS, GIS data, Monte Carlo-based simulation	(Züst et al., 2021)

Sensing layer

The sensing layer is the first and most fundamental layer within a DT architecture that employs one or more data-sensing devices to serve as the nervous system responsible for gathering raw data from the physical environment in which they were deployed. While only devices that stream data in a timely manner should technically be considered part of the sensing layer, static data sources (e.g., BIM models, GIS, schedules, and regulations) are also included to provide a more comprehensive overview of all data sources available for supporting a DT system. The selection of data sources and sensing technologies significantly affects the accuracy, reliability, and acquisition speed of raw data, and consequently, the efficiency and overall performance of the DT system. Thus, understanding the data requirements that align with the DT's primary purpose is crucial. Figure 4a maps the different sensing technologies employed within the CDT systems reviewed from the literature to the identified applications. The size of each node represents how frequently a technology was used. RFID was the most common sensing technology for safety and risk management implementations. GPS was widely used for progress monitoring, robotics, and logistics due to its real-time, precise location data for equipment, robots, and vehicles. IMUs followed GPS, mainly capturing motion data for progress monitoring and construction robotics.

Communication layer

The communication layer plays a key role in receiving the raw data acquired by the sensing layer and transmitting it to the CDT hub to be stored, processed, or visualized. Typically, the communication layer utilizes either a wireless network (e.g., Wi-Fi, Bluetooth, LoRa, 5G/4G cellular, etc.), a wired network (e.g., Ethernet, USB, and Fieldbus), or occasionally a hybrid of both. Figure 4b maps the identified applications to the different employed communication networks and protocols to give insights into their suitability and popularity. For example, Ethernet is featured in most studies related to controlling scale model robotics (Asadi *et al.*, 2018; Liang *et al.*, 2022). By employing the MQQTT protocol, Ethernet allows for bi-directional communication between the physical robot and its digital model enabling smooth robotic control (Han *et al.*, 2022; Liang *et al.*, 2022). Short-range wireless technologies (i.e., Bluetooth and Wi-Fi) are commonly utilized in various applications due to their higher transfer rates. Bluetooth Low Energy (BLE), a more energy-efficient choice compared to traditional Bluetooth, is also used in several studies as it is suitable for battery-powered devices and when long-period data collection with short-range coverage is required. Within long-range wireless technologies, LoRa is found to be a popular option for safety and risk management applications, specifically with hoisting operations owing to its long-range coverage (~10 km) and low-power requirement personnel (Zhang *et al.*, 2023). In general, selecting a communication network and protocols depends on several factors determined by the overall purpose of CDT including the required transmission rate, latency, range of coverage, security, and power consumption.

Storage layer

This layer provides a repository for hosting and managing the vast amount of data including the sensed raw data, data from other sources, and historical data. As shown in Figure 4c, cloud-based storage emerged as the predominant choice for data storage within CDT on account of its capacity to accommodate extensive data volumes and streamline their retrieval over the Internet (Pan and Zhang, 2021). Both SQL, relational databases, and NoSQL, non-relational databases, have been adopted in various construction applications. The selection of either relies on the types of data, its structure, and volume. For unstructured and variant data in substantial volumes (e.g., visual data), NoSQL is best due to its dynamic schema with higher scalability and adaptability. On the other hand, SQL is fit to manage well-defined data that has a structured schema (e.g., workers' information) as it gets arranged in structured tables with predefined relationships.

Analytics layer

This layer functions as the CDT brain in charge of processing, analyzing, and deriving insights from the collected data to support informed decision-making. Figure 4d maps the various data analytics techniques used for each CDT application. These techniques can be streamed into three main categories: a) ML-based methods that employ deep neural networks and object recognition and tracking algorithms (e.g., CNN, RNN, YOLO, and Deep SORT). b) Numerical/Simulation-based methods (e.g., Finite element method, discrete event simulation, queuing theory, Dijkstra algorithm, and genetic algorithm) that are mostly common with applications requiring simulation and optimization (e.g., equipment health monitoring, hazards identification, resource allocation, and material logistics). c) Human interpretation which is mostly featured in quality inspection applications where defects get visually detected in as-built data (e.g., point clouds). Construction robotic applications also highlighted human supervision for planning and remotely controlling robotic tasks.

Visualization layer

This layer enables the visual representation of the processed data and insights in a dynamic and interactive environment. Different visualizations can be employed within the CDT architecture depending on the data type intended to be visualized. For example, 3D data (e.g., point clouds and BIM models) are commonly utilized to visualize progress data for quality control and progress monitoring purposes. 4D BIM models are also employed to identify and visualize hazardous activities and locations and create safety precautions. Extended reality (XR) technologies are employed in various CDT applications as they allow stakeholders to intuitively interact with visualized data in an easily accessible way.

Several game engines and modelling software are featured within the literature to create 3D immersive environments. As presented in Figure 8, the “Unity engine” is the most used game engine for this purpose as it supports modeling and hosting DT entities, data integration from multiple sources, and running data analytics within its environment. Such features make it a favorable platform for visualizing DT data. Other game engines and modelling software are also highlighted, including Unreal Engine, and Blender platform. 3D visualization environments were not included in many applications (e.g., material logistics, embodied carbon estimations, and productivity measurements) as the type of data is mainly numerical and can be visualized using graphical representations within customized dashboards.

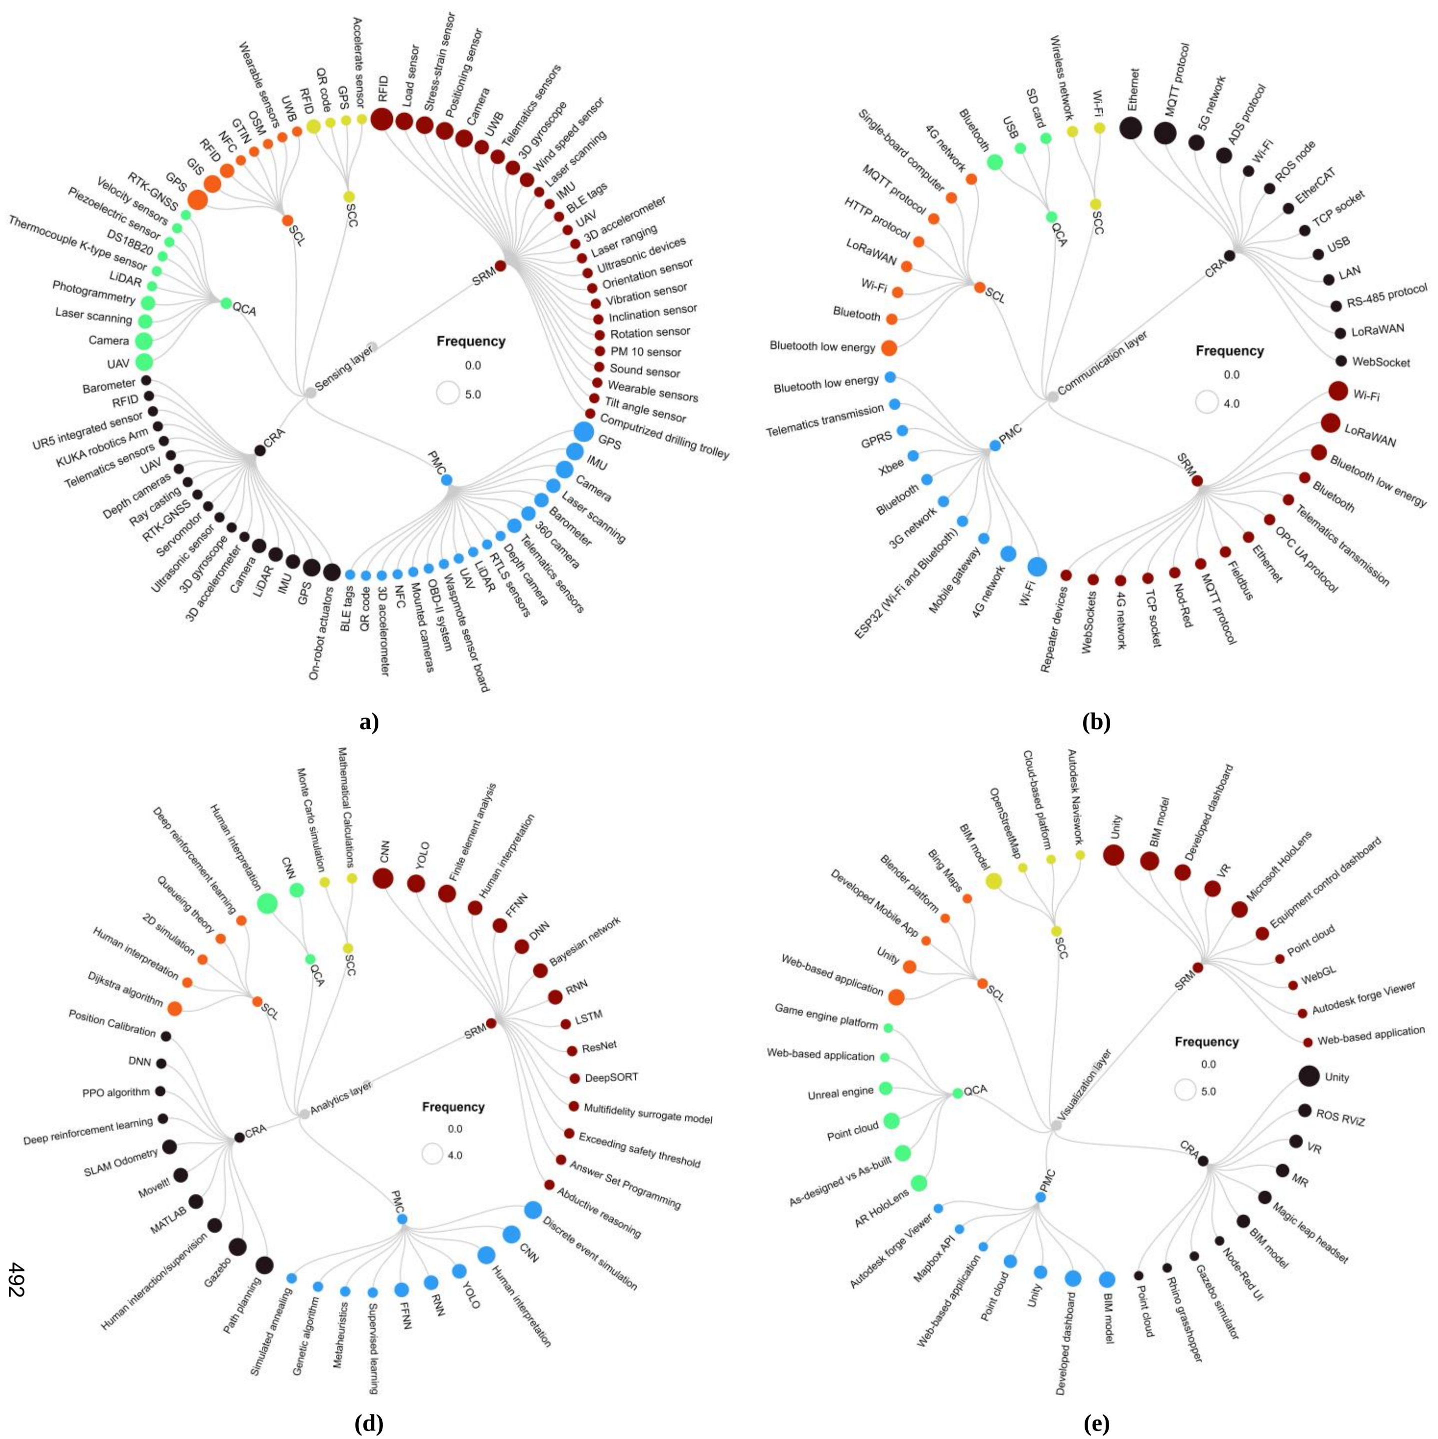

Figure 4: The different enabling technologies employed within each DT layer mapped to the identified applications: (a) Sensing, (b) Communication, (c) Storage, (d) Analytics, (e) Visualization.

Discussion

Evaluation of CDT applications

Comparing the findings of this study with previous review studies highlights the significant progression of DT implementations during the construction phase of built projects as most prior implementations are mainly focused on the operational and maintenance stage. Additionally, most construction applications highlighted in prior review studies are mostly nD BIM applications (e.g., clash detections, cost estimation, scheduling, and communication) (Boje *et al.*, 2020) or implementation of the integration of BIM with other technologies (e.g., XR, Simulation, AI). However, the thematic applications that emerged in this study are mainly DT-related implementations. Some of these applications align with DT research clusters categorized by (Jiang, Ma, *et al.*, 2021) in early 2021including safety, quality, and progress management. These applications have been expanded since then and new ones have emerged including construction robotics, logistics, and sustainability. Promising CDT research areas are recommended that are related to applications such as "circular construction", "embodied carbon estimations", "full-scale robotics", and "graph-based DT". New construction applications are anticipated to emerge, contributing to the increasing adoption of DT in both academia and industry.

What is CDT?

This section provides a discussion on the key attributes of a CDT system including the data acquisition mechanism, the feedback-decision making-loop dynamics, and the role of 3D modeling and BIM within CDT systems. Ultimately, synthesizing these discussions to propose a definition capturing the essence of CDT.

Data streaming mechanism

Almost all reviewed studies integrated at least one form of data sensing mechanism to provide DT with a dynamic stream of data without which a system cannot be considered as DT. Nonetheless, the level of automation, frequency, and latency parameters of data acquisition can all vary across different DTs based on several factors including the main purpose of the DT, the type of data that needs to be collected, and the rate at which is being updated. Several studies labelled their data-collecting mechanism as *"real-time"* or *"near-real-time"* without numerically defining these abilities in terms of latency and frequency. Only a few studies provided statistical information about these parameters to accurately reflect the capability of their data acquisition system (Deria *et al.*, 2022; Liang *et al.*, 2022; Posada *et al.*, 2022). Although in many articles especially within the manufacturing industry, being able to provide real-time data with high frequency and low latency is a requirement for a system to be a DT, in many construction applications that might not be achievable or even valuable. For example, in some applications, it was adequate to collect data, mostly visual, at a frequency of once a day (Hasan and Sacks, 2023; Pour Rahimian *et al.*, 2020; Zhao *et al.*, 2022). Yet, in other applications where data gets updated more dynamically, a higher frequency is essential. For instance, for tracking the angle movement of a robotic arm, a frequency of up to 250 Hz might be required to synchronize with the rapid rate of update of the moving arm (Liang *et al.*, 2022).

In general, acquiring vast amounts of construction data with high frequency might not be needed and comes with high costs and significant environmental impact associated with collecting, transmitting, storing, and processing this data. Therefore, when designing a DT, these attributes should be optimized to create a balance of being efficient and meeting its overall purpose requirements. Similarly, the degree of autonomy in data acquisition varies widely, with some cases featuring semi-automated approaches, particularly in laser scanning and photogrammetry where human intervention is required for capturing and processing the visual data. In contrast, many studies employ fully automated sensing sources, like positioning sensors capable of transmitting data without any human involvement.

This is to emphasize that the spectrum of data acquisition capabilities for DTs is broad, and achieving a fully automated data stream within specific latency and frequency parameters is not always a must-met criterion for classifying a system as a DT.

Feedback loop—decision making—dynamics

The majority of the DT research in digitally advanced fields (e.g., manufacturing) emphasizes automated bi-directional communication between the physical entity and its digital counterpart (Ladj *et al.*, 2021). In manufacturing, its typically well-designed and controlled environments (e.g., an assembly line) enable the establishment of an automated feedback loop. However, with dynamic, variant, and unpredictable construction operations, establishing an automated feedback channel from the DT to the site can be challenging. Instead, the feedback in some construction applications often involves visualized insights presented to stakeholders for decision-making, highlighting a human-oriented feedback channel, (see Figure 3). For instance, within progress monitoring applications, site stakeholders are presented with performance metrics, which they then align with baseline targets to inform their decision-making.

Almost all construction robotics and automation applications feature fully automated feedback channels where control instructions are given back to a prototype machinery or a robot to conduct a desired task based on the acquired data. Nonetheless, most of these studies used scaled machinery or robotic assembly to validate their systems, raising concerns about their scalability and real-world construction site applicability. Automated feedback was also employed in some safety applications in the form of proactive visual or audible warnings automatically triggered when a potential hazard is detected (Jiang, Ding, *et al.*, 2022; Zhang *et al.*, 2023).

BIM-CDT relationship

The relationship between DT and BIM has been a subject of debate among researchers, with some viewing DT as an extension of BIM with the incorporation of new technologies (e.g., IoT, AI, and simulation), while others perceive them as two distinct concepts with significant differences in their characteristics and applications. In many applications where objects' non-geometric information (e.g., attributes and relationships to other objects) are the main data of interest rather than the geometric information, BIM may not always be necessary for DT functionality and simple 3D models with low Level of Detail (LoD) would be enough for visual representation.

Examples of such applications are workers' health monitoring where workers' information and status are of interest or in material logistics where material quantities or locations are tracked. Nevertheless, in several applications, BIM models were still integrated into CDT layers, serving different purposes as follows: a) within the sensing layer as a source of static data (e.g., schedule, quantities, semantic and geometric data); b) within a storage layer as a unified storage model that integrates and stores various relevant data; c) provides a 3D visualization and interactive environment, possibly integrated with dashboards, within the visualization layer.

A proposed CDT definition

Several definitions of DT exist within the construction industry, often borrowed from advanced sectors like aerospace and manufacturing, where the term originated and developed. These definitions typically include terms like virtual replica, 3D model, digital counterpart, realistic model, and real-time representation of physical. However, a critical question arises: Is DT primarily about high LOD modeling and replicating physical objects, or is it fundamentally about data management and informed decision-making? Particularly in construction implementations, the focus is more on data capturing and analysis that enables informed decision making rather than 3D replication or modeling. Then, there is a need for a definition that emphasizes the data management aspect of DT in construction. Drawing insights from the extensive literature review and the conceptualized DT architecture in Figure 3, this study proposes the following definition:

> *Construction Digital Twin (CDT) is a system responsible for collecting and processing construction dynamic data about a physical entity within the intended application's temporal demand, translating this data into actionable knowledge to enable informed decision making.*

"*Dynamic data*" refers to data that is continuously changing and collected through automated sensing mechanism. It is important to note that CDT can also combine static data from BIM models or historical records to supplement the dynamic data when needed. A "*physical entity*" can be a tangible object (e.g., a structure, equipment, or person) or a physical process (e.g., material delivery or element installation). "*Temporal demand*" acknowledges the varied data latency and frequency requirements across different DT construction applications, as discussed earlier. Consequently, terms like "real-time" and "near real-time" are avoided to highlight the variability in data capturing and processing rates and the lack of precise numerical definitions for these terms. Informed decision-making can be either fully automated or human-assisted, as illustrated in Figure 3.

Literature gaps and recommendations for future research

- Many of the reviewed studies relied on a single sensing source for data acquisition mainly to avoid the challenges of integrating data streaming from multiple sources with different formats. Still, it is frequently stated that depending on a single source for onsite data falls short of providing accurate and comprehensive insights into scalable operations (Hasan and Sacks, 2023; Hoffmann et al., 2022; Pan and Zhang, 2021; Salem and Moselhi, 2021). Only by merging data from multiple sources, a better understanding of construction operations and better-informed decision-making is obtained. Hence, it is recommended to aim at integrating heterogeneous data across multiple domains, leveraging sensor fusion to bridge this gap. Moreover, publishing well-defined data schemas for construction applications can facilitate representing complex information and potentially contribute to developing industry standards.

- Another gap is the absence of standardisation in DT design and deployment including the configuration and specifications of key parameters including data acquisition frequency and latency, analytics accuracy, and its degree of autonomy. Most studies loosely labelled their DTs as "real-time" or "near-real-time" systems without numerically defining those parameters and linking their defined attributes to the DT's main purpose.

- Besides, many studies showcased a limited scope by carrying out a single data collection trial, failing to illustrate how the data and analyzed metrics are regularly updated in a timely manner. This raises questions about the usability, scalability, and versatility of their DT systems. Standardizing DT implementation is key for facilitating its adoption in the industry as it ensures consistency and compatibility.

- Several studies relied on human interpretations for analysing the collected data. This is especially the case with most of the quality inspection and progress tracking applications. Even when automated data analytics are integrated, they are limited to presenting descriptive analytics ("What has happened? As-is analysis"). Only a few studies employed predictive analytics (Lee and Lee, 2021; Li et al., 2021). It is recommended for future research to gear towards enabling CDT to provide predictive ("What will happen? -To-be analysis") and prescriptive analytics ("What should be done? -What-if analysis") by integrating advanced AI and simulation techniques. Doing so will unlock the complete potential of CDT as a proactive decision-support system.

Conclusion

This study serves as a valuable resource for researchers and practitioners in the construction industry by presenting a structured taxonomy of CDT applications and their interaction with different technologies through systematic review and thematic analysis. Seven main thematic applications of CDT are identified and discussed. Additionally, a conceptualized architecture of CDT, comprising five distinct layers, is proposed to aid in exploring and analyzing enabling technologies and processes, and mapping them to the identified applications. The paper also explores and discusses the characteristics that define the essence of CDT and proposes a definition emphasizing its focus on data management and decision-making. These findings not only consolidate existing knowledge in the CDT domain but also provide a foundation for guiding future research and development in this field.

CAPTURING REALITY CHANGES FROM POINT CLOUDS FOR UPDATING ROAD GEOMETRIC DIGITAL TWINS

Diana Davletshina[1], Varun Kumar Reja[1], and Ioannis Brilakis[1]
[1]University of Cambridge, Cambridge, UK

Abstract

Proactive maintenance of roads enables increased asset lifespan with improved safety and minimised downtime. However, the absence of up-to-date structured information leads to expensive reactive maintenance. Geometric digital twins (GDT) provide digital replicas of object geometry, but no automatic tools exist to maintain them. This paper develops a method for detecting and applying geometric changes to road GDTs. Our solution performs a distance-based comparison of point clouds, estimates the changes and then applies them to GDT. It achieves a 77.87 F1-score in detecting changes and significantly saves time by automating the process, making such digital twins viable and practically applicable.

Introduction

The average travel delay in the United Kingdom has increased by 40% over the past three years due to roadwork disruptions, causing decreased journey time reliability and slower highway speeds (National Highways, 2023). These delays are not just inconvenient but also economically impactful, potentially leading to a £0.50 loss in Gross Value Added per hour per person in Britain (Confederation of British Industry, 2017). Efficient transportation infrastructure, crucial for economic productivity, requires up-to-date information on road assets, with road geometry playing a vital role in traffic safety and operational efficiency (Design Manual for Roads and Bridges, 2020). Road geometric digital twins (GDT) enable such monitoring of road conditions and infrastructure health, offering near real-time data integration and detailed replicas of road systems (Steyn and Broekman, 2022). The life-cycle of GDTs includes construction from point clouds and optionally images and ongoing maintenance to reflect changes in the road infrastructure (Drobnyi et al., 2023; Osadcha et al., 2023). This paper focuses on automating the stage of GDT maintenance, which is a substantial part of the GDT life-cycle.

The main challenge in integrating GDTs is their high cost of maintenance that outweighs potential benefits, introducing a significant barrier to their widespread adoption. This research aims to reduce these costs, eliminating the manual work involved. Specifically, maintaining kilometres of roads requires manual effort in identifying changes and modelling various changed road assets (Davletshina and Brilakis, 2023). Although current research has automated parts of this process, it falls short in scope, often failing to cover a wide range of objects and identifying specific changes that happened to the assets. Additionally, there is a need for a comprehensive and automatic end-to-end pipeline for change detection, followed by applying these changes to GDT.

This paper aims to facilitate efficient, proactive maintenance by providing a tool to update a geometric digital twin automatically, thus delivering a fresh version of GDT quickly and cheaply. We achieve this by first comparing point clouds for changes, identifying the types of changes and applying them in GDT in a streamlined, fully automatic pipeline. Exemplar input and outputs can be seen in Figure 1. The solution covers all the object classes that are already present in GDT. Thus, the solution is flexible and not hard-coded to the specific entities. Furthermore, we consider the wide range of change types in the scope of our work: a) the same object is there, but it underwent pose (rotation and translation) changes; b) the same object is there, but it underwent shape deformations; and c) the object is removed or added. As a result, we detect most of these changes and achieve 77% F1 score.

The organisation of this paper is as follows. The next section discusses the background literature on maintaining GDTs. Then, section Proposed Solution introduces the proposed automatic digital twin maintenance method. Research Methodology, followed by the Results and Discussion section, can be found further. The conclusions of the study are presented in the last section.

(a) GDT (old).

(b) GDT (new).

Background

The evolution of Digital Twins (DTs) presents a complex challenge, particularly in their efficient updating, which remains unresolved. Schrotter and Hürzeler (2020) highlighted the difficulty in updating urban DTs, highlighting the vast volume of 3D data as a significant obstacle to process. Nevertheless, ongoing research within the built environment sector is actively investigating various methods to effectively maintain and manage digital twins and 3D models of infrastructure assets.

Updating GDTs of built assets starts with collecting appropriate data on the physical counterpart. Osadcha et al. (2023) found that photogrammetry and laser scanning are the primary means for data collection and capturing 3D information. While photogrammetric methods are cheaper, they produce less accurate depth data due to lighting and shadow artefacts (Stal et al., 2013). Mobile laser scanning could serve as a compromise between various methods from images to static scanning, allowing faster operation while driving but producing sparser point clouds than static counterparts (Soilán et al., 2019). Collected data then requires further processing.

A critical step in maintaining GDTs is effectively detecting changes in the data collected at different timestamps. Stilla and Xu (2023) explored this, identifying several types of changes in urban objects using 3D point clouds. They distinguished the following possible change types: appeared, disappeared, partially and fully moved, deformed and unchanged, highlighting that the most common types were the first two, while partial movement was used when detailed changes were required upon use case. Their work estimates point-based, segment- or object-based spatial differences after having point clouds registered. While point-based methods rely on accurate distance measurements, segment- and object-based methods depend on the accuracy of the classification provided. Recent works use deep learning solutions to provide semantic labels and discover further opportunities to match changes with machine learning.

In this realm, Zhu et al. (2023) introduced a method for multi-object relocalization and reconstruction in the segmented into instances 3D point clouds. They could match, register and reconstruct the objects of the input scenes using a deep learning approach, namely an encoder-decoder network. Although solving three tasks simultaneously, they envision the challenge of large-scale spatiotemporal changes yet to be addressed.

Developing dynamic Building Information Models (BIMs) from 3D point clouds is another key research direction in this field. Rausch and Haas (2021) developed a dynamic BIM by updating BIM elements' shape and pose from 3D point clouds, utilising optimisation of geometric object parameters. Despite achieving below-centimetre accuracy, their method's reliance on generic shapes limits its effectiveness with free-form objects. Alternatively, Ghahremani et al. (2018) used 3D point clouds for structural condition monitoring, comparing different-timestamp point clouds to detect deterioration. They identified changed areas by discrepancies between as-built and as-is point clouds, using meshing to update the model. Shellshear et al. (2015) adopted a simpler approach for 3D model maintenance, employing repeated scans from fixed viewpoints and markers to automatically update regions in the target model with point clouds. While effective for built assets, these methods highlight the need for focused approaches in maintaining GDTs for roads.

Knowledge Gaps, Research Objectives and Questions

Maintaining GDTs for roads involves two primary phases: detecting changes and applying these changes. However, a fully automated system for this task is yet to be realized. Also, current methods do not encompass most road assets, such as the frequent objects identified in the work of Davletshina and Brilakis (2023), highlighting a significant gap. While researchers have primarily focused on automating aspects such as identifying temporal changes, further development is still needed. Although advancements in built asset management provide insights, there remains a critical need for domain-specific adaptation and refinement of these solutions to cater specifically to road infrastructure.

This context sets the stage for our objective: to propose and develop a fully automated method for maintaining road GDTs. We outline the following key research questions in addressing our objective: 1) What approaches are most effective for detecting changes in road environments? 2) What strategies should be employed to efficiently apply detected changes to GDTs? 3) Is it possible to devise a versatile method adaptable to various road environments and infrastructures? Addressing these questions will be pivotal in advancing the field and ensuring the accuracy and relevance of road GDTs in a dynamic and evolving landscape.

Proposed Solution

Our approach to detecting and analysing temporal changes in geometric data employs a dual-layer methodology, as illustrated in Figure 2. This is necessitated by the requirement to initially discern the nature of any changes (Change Detection Layer), followed by appropriately addressing the identified changes (Change Application Layer). Initially, the method involves a comparative analysis of point cloud data, representing different states of a physical environment captured at distinct times. As the two point clouds will not contain the same point set, we take advantage of comparative distances to estimate high discrepancies. The framework commences with the older Geometric Digital Twin (GDT) version, incorporating the original point cloud and the newly acquired point cloud for subsequent change detection and processing.

The procedure begins with a thorough analysis of the input point clouds to identify changes by computing distances between points. The algorithm targets areas exhibiting significant alterations, i.e., large distances, indicative of substantial environmental changes. Thus, we filter these points using a distance threshold, which is a hyper-parameter to be tuned. Upon pinpointing these areas, we anticipate that most changes, unless due to extensive road reconstruction, will be isolated to individual objects, as road infrastructures typically undergo minimal alterations. As a result, we have these isolated change points, i.e., filtered with the threshold and as a result isolated in space point clusters featuring high distance values such as in Figures 3d and 3e. Then, we apply the DBSCAN clustering algorithm (Ester et al., 1996) on these points – known for its effectiveness with noisy data and not requiring pre-set cluster numbers – which facilitates the segregation and extraction of clusters (e.g., denoted by different colours in Figures 3d and 3e) and their associated objects as identified in the current GDT, enabling a more focused examination.

Subsequently, the nature of the detected changes guides the ensuing steps. For each cluster, the algorithm first finds the closest correspondences between the two versions and ascertains whether the change is an addition, a removal, or a transformation of an existing object. Additions and removals are identified similarly, as they can be seen as the same operation but in opposite sequences. We consider that addition or removal happened if the closest corresponding cluster was already linked to another cluster with a smaller distance. Otherwise, we consider that there was a pose change.

Objects identified as removed are excised from the dataset while new additions are integrated. In cases where existing objects have undergone modifications, the Iterative Closest Point (ICP) algorithm (Zhang, 1994) is deployed on the found cluster correspondences (i.e., correspondence pairs) to compute the transformation, encompassing both rotational and translational adjustments between them. This process begins with estimating the initial transformation for a global match, then minimising the distance between two shapes to locate the closest points. This phase is pivotal in deciphering how the object has shifted or evolved over time. Depending on the nature of the change, the algorithm either applies a transformation to align the old and new states of objects with pose changes if any pose changes were found or otherwise updates the GDT to mirror the new geometry of deformed objects by replacing the object. As a result, an automatic command is sent to perform these described changes to the GDT.

Consequently, our solution presents a systematic and flexible framework for temporal analysis of point cloud data concerning roads, resulting in an up-to-date GDT reflecting reality. This fully automated and scalable solution can be applied over extensive road lengths, significantly enhancing our comprehension and monitoring of environmental alterations across various applications, from asset maintenance to safety analysis.

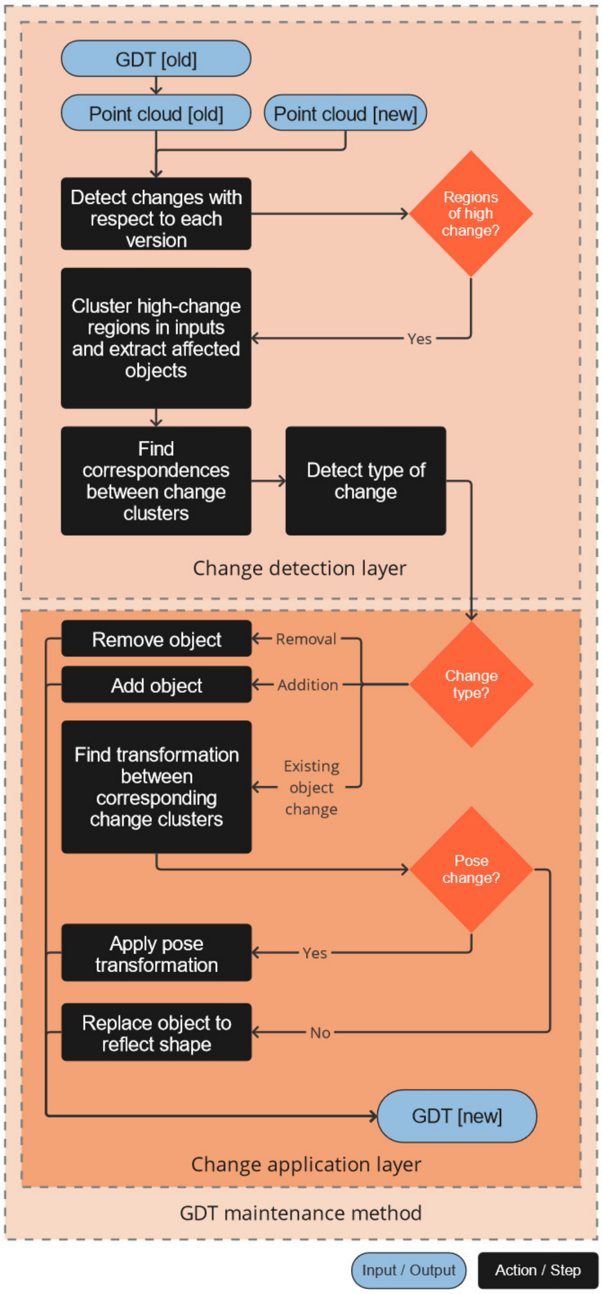

Figure 2: Solution overview.

Research Methodology

We use the Digital Roads (Digital Roads of the Future, 2023) point cloud dataset, which contains 11 labelled classes. We limit the data to the A11 road subset, which comprises 20 road segments, each 200 meters long. As the study conducted in this paper requires time-series data with changes, we synthetically generate the changed version of the point clouds (the *new* state) from the existing dataset (the *old* state) due to the unavailability of a real-life data. We introduce specific perturbations to the data for sufficient differences between data to simulate real-life scanning. For that, we add random noise to the coordinates of both versions of the data (the *old* and *new* states). The noise is normally distributed around mean 0 with a standard deviation of 0.01. Furthermore, we randomly downsample both versions such that 20% of the points are removed. We simulate the changes to the road infrastructure, namely road barriers, traffic signs and lamps, such as fallen assets, leaning assets, missing assets and moved assets in the *new* version of the point cloud. We consider removals of the existing objects and additions of the new objects in the case of the missing objects. These scenarios are seen to be equivalent as one object is missing in one of the versions of scanning.

Our assumptions are as follows. Firstly, we assume that the GDT is semantically labelled and has its original point cloud stored as meta information. If that is not the case, then a synthetic point cloud is expected to be created from the GDT's 3D model. Secondly, we assume that point clouds are registered with each other; data registration is out of the scope of this work. Lastly, we assume that new scanning is performed before new furniture is installed to avoid confusion between removed and newly added assets' pairs.

We use the threshold-based method to identify high-change regions, with the threshold hyperparameter equalling the 0.99 quantiles. Further, we use the DBSCAN clustering algorithm (Ester et al., 1996) to cluster these high-change regions with the following hyperparameters: epsilon equal to 3 and minimum points per cluster equal to 10.

We provide the metrics of precision (Formula 1) showing how many changes were correctly classified, recall (Formula 2) giving the number of correctly predicted items among all correct items and their harmonic mean as F1 score (Formula 3). In the formulas, *TP* refers to true positives, denoting the number of data points classified correctly as positives, *FP* – false positives, denoting the number of data points classified incorrectly as positives; *FN* – false negatives, denoting the number of positive points predicted as negatives. We calculate precision and recall values for each sample and report averaged final metrics.

$$Precision = \frac{TP}{TP+FP} \tag{1}$$

$$Recall = \frac{TP}{TP+FN} \tag{2}$$

$$F1 = \frac{2*Precision*Recall}{Precision+Recall} \tag{3}$$

Results & Discussion

Figure 3 demonstrates the solution's inputs, intermediate and final outputs. Our method can find the changed regions, such as in Figure 3c, where the two input point clouds (Figures 3a and 3b) are aligned. These divergent regions are clustered, as in Figures 3d and 3e, and matched, as well as their transformations are estimated (Figure 3f). As a result, our solution finds pose changes with 90.97% precision and 68% recall (Table 1). The method misses out on a few samples where the changes are minimal, such as small translation and rotation angles. Further, vegetation represents a challenge, introducing additional high discrepancies. Thus, vegetation should be considered for filtering out beforehand using vegetation detection solutions. Additionally, the intermediate found change clusters (e.g., Figures 3d and 3e) come with a certain amount of noise either within clusters or outside of them, which might be considered as a potential scene alteration. As this confuses the method, noise removal at this stage must be included in future work.

Furthermore, the algorithm faces challenges in accurately matching changed clusters when they are significantly distant from each other, particularly in situations where multiple similar changes occur concurrently within the same scene. Handling such intricate change scenarios effectively requires more advanced algorithms for object matching. Incorporating prior knowledge could be crucial in these contexts, aiding in differentiating between scenarios where objects have been moved as opposed to those where objects were removed and replaced with similar ones.

Conclusions

In summary, this work presents a method for maintaining up-to-date geometric digital twins of roads in a fully automatic manner. This method is distinguished by its flexibility and adaptability, which is capable of handling a wide range of objects based on the semantic labels provided in the input GDTs. Our approach goes beyond mere change detection in point clouds; it integrates these changes directly into the GDTs, thereby forming a seamless, end-to-end pipeline that extends from initial scanning to the final GDT for road infrastructures. This development paves the way for the broader implementation of geometric digital twins in the transportation sector, offering significant benefits from the design phase to asset management. This is achieved with reduced costs, courtesy of the automation process. Enhancing the productivity of the sector will yield positive outcomes for road users, including improved connectivity, fewer road closures, and reduced emissions, ultimately leading to a more efficient and environmentally friendly transportation experience. Looking forward, we propose that future research should concentrate on collecting comprehensive datasets that capture real-life temporal changes, tackle the challenges presented by complex and large-scale transformation scenarios, and harness the potential of deep learning for enhanced accuracy in change detection.

DATA QUALITY IN THE BUILT ENVIRONMENT ACROSS EUROPE

José L. Hernández[1], Susana Martín[1], Vanja Lonac[1], Ignacio de Miguel[2] and Alessandro Rossi[3]
[1]CARTIF technology centre, Boecillo, Spain
[2]Universidad of Valladolid, Valladolid, Spain
[3]Engineering Ingegneria Informatica S.p.A., Palermo, Italy

Abstract

Energy efficient projects are usually based on data to take better-informed decisions. High-quality data is necessary to reduce the uncertainty, which is a challenge to solve data gaps and/or outliers, thus limiting the trustworthiness in the decision-making. High-quality data is essential for assessing energy usage, identifying improvement measures and implementing effective solutions. This paper presents a data quality methodology, based on seven dimensions and validated in ten pilots across Europe. The maturity levels in the monitoring stage are crucial. Completeness, accuracy and consistency values vary between 40%-99%. It indicates the need for creating correction procedures and increasing the data quality.

Introduction

The increasing adoption of leading-edge Information and Communication Technologies (ICTs), such as Internet of Things (IoT), Artificial Intelligence (AI), Distributed Ledger Technology (DLT), Blockchain or Big Data (BD), as well as the wider extension of Building Automation and Control Networks (BACN) existence (mainly in tertiary buildings), has motivated the generation of big amounts of data in the building domain.

Even though over the past two decades, there has been an increasing focus on the digitalization of building data, and more and more data are being generated by the building stock, data quality remains a challenge (Duvier et al., 2008). There are data gaps, errors and inconsistencies in registrations that still need to be addressed. In contemporary construction and building projects, data plays a pivotal role in decision-making processes, project management, and overall success. However, the quality of data used in these endeavours often falls short of desired standards, posing significant challenges throughout project lifecycles. Poor data quality in building projects presents multifaceted obstacles, ranging from increased costs and delays to compromised safety and functionality.

Additionally, nowadays data-driven approaches are being followed, but here the main challenge is related to the reliability of the results due to data issues (e.g. communication or infrastructure problems) (Yong et al., 2021). One of the major challenges is to be able to process and analyse the data traceability to detect the errors (Hossein et al., 2020). The big amounts of data being generated make this analysis more and more complex. In terms of data governance, there is no consensus about the meaning of this term (Ender, 2021). However, different types of data should be considered when determining the ownership, which is even more complex when non-human data is included. These data are produced and treated in silos, without correlation between pillars (Abraham et al., 2019), which will promote better exploitation potential.

Poor data quality can also hinder effective stakeholder communication and collaboration, exacerbating misunderstandings and conflicts among project participants. In the absence of reliable and up-to-date information, decision-makers may resort to subjective judgments or outdated assumptions, further compounding project risks and uncertainties.

All these challenges are contributing to move forward towards the creation of a high-quality data-driven Smart Buildings Landscape. Data concerns almost every aspect of the built environment: from how individuals and businesses use and interact with properties, to how the building's energy consumption and construction details are recorded and analysed to support informed decisions about construction and real estate processes. Data-informed decision-making and digital upgrading can help upyield operational efficiencies at low cost.

A proper validation and detection of gaps, wrong and/or inaccurate data in the whole value chain of the building monitoring is a crucial step towards transparency and trust of the involved actors during the decision-making process to achieve the objectives of the Energy Performance of Buildings Directive (EPBD, 2023) of ensuring low usage of energy, low rate of carbon footprint, maximizing thermal comfort or assessing air quality.

According to the BDVA (Big-Data Value Association), the data quality concept is too absolute and misleading (BDVA/DAIRO, 2021). Within this paper, the high-quality data concept is based on the following aspects, establishing performance metrics as BDVA also suggests:

Reliability & Credibility: a data quality methodology is defined, deployed and applied, based on ML algorithms to learn about historical data, for reducing and correcting data errors not only in the data gathering process, but also in the propagation. This methodology takes care of:

(1) Data gaps, in terms of missed data to detect non-completeness and creating interpolation methods when possible, to generate continuous data streams for dynamic timeseries. As well, for static and contextual data, completeness in terms of missing data to be completed with other sources (e.g. digital logbook missing data and cadastre information);
(2) Outliers that are produced by values that differ from the expected measurements, thus, reducing the uncertainties of data analytics.
(3) Consistency and accuracy by removing duplicates, aligning multi-source measurements (e.g. date/time in timeseries data from various sources) and cleaning ambiguous values.

(4) Model check, which is focused on static data (i.e. BIM-Building Information Modelling). Errors in the building modelling are usual and propagated to the tools for the building life-cycle management. These mistakes should be prior detected and solved whenever possible.

Interoperability: Better-informed decisions mean using combined data from heterogeneous sources (e.g. sensors, energy performance certificates databases, digital logbooks, BIM, CityGML, Level(s), etc.), but the lack of interoperability is an issue to merge these datasets. To solve this, dynamic and adaptative interoperability will be ensured by using standard Data Models (such as NSGI-LD, SAREF, BRICK or IFC, among others) to accommodate data into the requirements of the use cases or services to be deployed.

Privacy & Security: Last but not least, quality also involves privacy (personal data management) and security. DLT and blockchain framework can be applied here, where privacy and security are the main benefits.

Addressing the challenges stemming from poor data quality in building projects is paramount for the sustainable advancement of the construction industry. By assuring these aspects, buildings' stakeholders can rely on the data analytics and data-driven services thanks to high-quality data stocks. Additionally, the creation and use of data-driven business models will be built on top of high-quality data, providing more accurate and trustworthy value (e.g. ESCO-Energy Services COmpany models where energy prices are based on performance calculation and energy savings could be calculated using wrong data).

Real-world cases abound where the repercussions of inadequate data quality have been acutely felt, leading to suboptimal project outcomes. For instance, consider the scenario of a large-scale infrastructure development project where inaccurate site survey data resulted in improper foundation designs, ultimately leading to structural instability and substantial rework costs. Similarly, in the realm of building information modelling (BIM), incomplete or inconsistent data inputs have led to coordination errors, clashes between different trades, and inefficiencies in construction sequencing. Another example could be obtained from ESCO services, whose main challenge is the data collection from smart meters. Data gaps are usually appearing, leading to more complex billing procedures due to missing data, as well as the limitations in the energy savings calculation.

In summary, this paper presents how the previous challenges are overcome by deploying a data quality methodology that covers the data life-cycle of the building, delving into the complexities surrounding data quality issues. It will not be only focused on the data gathering at field level, but it will cover the different stages of the building and data lifecycle to reduce the error propagation. This methodology will be supported by a federated Data Lake (Hernández et al., 2023a) (deployed within a data platform) to collect cross-domain data, being able to benefit the data management and governance processes. Finally, the data platform will provide additional services, which will facilitate the management of data ownership, and together with blockchain, will allow traceability, privacy and security of data stocks.

The rest of the paper is structured as follows. The following section presents the literature review in terms of data quality (including real-case scenarios). Next, the data quality methodology is explained, to be later applied in 10 pilots composed by one or several buildings. Results of the data quality assessment are collected into the "Data quality analysis results" section, where statistics for the 7 data quality dimensions are presented per pilot. A "Discussion" sections follows, to highlight the dependency of the buildings' data quality values to the age of the building and monitoring maturity and stage. Finally, the main remarks of the paper are presented in the "Conclusions" section.

Literature review

The literature provides various definitions and dimensions of data quality in the context of smart buildings. While traditional data quality dimensions such as accuracy, completeness, consistency, and timeliness remain relevant, the dynamic nature of IoT-generated data introduces new challenges and considerations. The importance of additional dimensions such as interoperability, security, privacy, and relevance in assessing data quality in smart buildings is emphasized (Rao, 2023). Ensuring data compatibility and integration across heterogeneous systems while safeguarding privacy and security concerns emerges as critical areas of focus.

Despite the potential benefits, smart building deployments encounter numerous challenges related to data quality. These include issues such as data silos (Hernández et al., 2023b), interoperability gaps between devices and systems (Coujard, 2023), sensor inaccuracies, data integration complexities, and cybersecurity vulnerabilities. The literature highlights organizational barriers such as lack of data governance frameworks (Kaginalkar, 2023), limited expertise in data management, and resistance to change as significant impediments to achieving and maintaining high data quality standards in smart building initiatives.

Diagnosis of data quality is therefore a main challenge. Some authors have analysed the uncertainty in the calibration of the measurements (Morewood, 2023). It is reported that, in 43 out of 63 real-cases, overall accuracy is achieved, while precision is reduced up to four. Calibration is shown in 18, whereas measurement out-of-range is only reached in 23. Another real-case scenario is performed in the cites of Nantes, Hamburg and Helsinki (Hernández et al., 2022). The main conclusion is the real need for methods to increase data quality to foster better-informed decisions. The authors demonstrated the low quality of various data-sets in terms of completeness and out-of-range, highlighting the importance of proper commissioning mechanisms.

Complementary to these previous studies, the contribution of this work extends the data quality analysis to additional real-case sites across Europe to understand the real data-quality scenarios. Moreover, while previous researches limited the dimensions of the data quality, this manuscript increases the dimensions, covering accuracy, completeness, reliability, consistency, relevance, accessibility and timeliness. This work has been carried out within the EU HORIZON DigiBUILD project, whose main aim is to transform traditional silo approaches by making use of high-quality data and next generation digital building services for assuring trust and transparency, and better-informed decision-making processes. It counts on ten pilots across Europe where the technologies are tested.

Data quality methodology

Within DigiBUILD project, a multi-dimension strategy is approached in terms of data quality. Table 1 summarizes the list of dimensions that are part of the data quality analysis. From the 7 dimensions, accuracy, completeness and consistency are considered the pivotal ones.

Table 1: Data quality multi-dimension approach

Data quality dimension	DigiBUILD approach
Accuracy	Out of "expected" range detection
Completeness	Gap detection and interpolation
Reliability	Accuracy x completeness
Consistency	Detection of "normal" data patterns & Proof of Existence (PoE)
Relevance	Data filtering processes
Accessibility	Open APIs and protocols
Timeliness	Pre-analytics

Accuracy determines the percentage of data samples compliant with the "expected" ranges. It should be clarified the "expected" range differs from the measurement range. For instance, an indoor temperature sensor can obtain data within values from 0ºC to 50ºC (depending on the manufacturer). However, temperature are expected to be around 15-30ºC (depending on the building use, insulation level and other features). The accuracy dimension treats the detection of data samples, which, even correct, are out of this range to avoid its usage in the application of services (i.e., classified as outliers). Within DigiBUILD, the procedure calculates the data samples within the range specified by the building expert, manager and/or operator to extract the ratio with respect to the total number of samples.

Completeness goal is to determine the data gaps that are in a dataset. Normally, data samples are periodically collected according a sampling frequency. Therefore, the total samples to be gathered in a time span are known. Thus, the missing data can be calculated by the ratio between the available data samples and the theoretical ones to be saved.

Reliability focuses on the feasibility of data to carry out analysis, develop high-level services or provide high-quality data to third parties. This dimension correlates the completeness and accuracy to provide an overall mark.

Consistency looks for the data patterns within data. For that end, normal distribution is considered, where measurements are scattered between the mean and ± standard deviation.

Relevance dimension is helpful to determine the datasets that are really useful from the end-user's perspective (services). Data normally include data-points without any usability in the implementation of the services; therefore, the percentage of relevant data is the main purpose.

Accessibility provides the ability to access, gather and share data. Here, the use of open protocols and APIs (Application Programming Interfaces) fosters the accessibility to the datasets. Nevertheless, this is not always possible, limiting the access to some datasets. Thus, this dimension checks the ability to access the relevant data from the building.

Timeliness is related to up-to-date data or the delay to gather the information that is required for making informed decisions. It is expressed in time units in order to establish the maximum delay when data is made available.

Table 2: Data quality outcomes within DigiBUILD

Data quality dimension	DigiBUILD outcome
Accuracy	> 85%
Completeness	> 90%
Reliability	No duplicates (clean data)
Consistency	Increase 10%
Relevance	90% of useful datasets
Accessibility	90% of data accessible
Timeliness	Specific per pilot

With regard to the results to be obtained in DigiBUILD, Table 2 shows the outcome that should be achieved by the detection and the correction techniques to be applied. In this sense, the accuracy and completeness dimensions should reach 85% and 90% respectively to provide a clean dataset without duplicates (reliability). Moreover, the case of consistency aims to improve the quality of the datasets being used in a 10%, making relevant the 90% of the collected dataset with an accessibility of 90%. Finally, timeliness depends on the specifications of the pilots when data is polled / pushed.

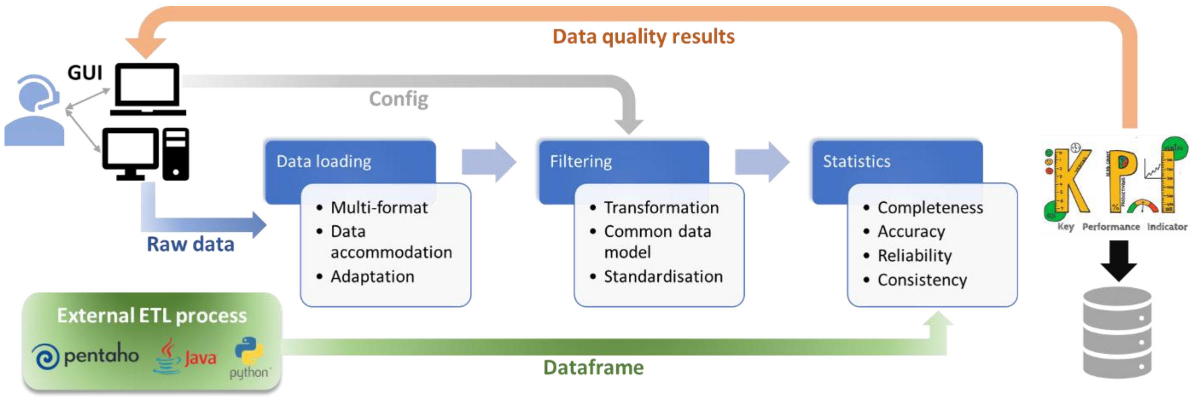

Figure 1: Data quality detection and check approach

Data quality check approach

Two procedures are approached for data quality assurance. On the one hand, the checker in charge of the analysis of the quality of datasets; on the other hand, the methodology for the correction of data (such as interpolation or other techniques for data cleansing). However, this paper is focused on the status of the data quality across Europe; therefore, the correction part is out of the scope. It will consist of a machine-learning approach to learn from historical data. Then, when a gap or an inconsistent data measurement is obtained, the corrector module will populate data according to the data-driven model.

Focusing on the checker, Figure 1 depicts the schema how it is approached within DigiBUILD. It works on two possibilities. The first one makes use of downloaded data from the pilots, for instance, csv files, Excel sheets, JSON documents, etc. This raw data is ingested by a data loading module that accommodates the multiple formats and adapts them in order to be transformed (filtering process) into a common data model. The goal is to provide a "standard" representation of data (following a python DataFrame). Complementary, a configuration file is used where the user provides the parameters and specific aspects related to data.

The second way is the use of data collection technologies, as for the case of Pentaho (Hitachi, 2023), python or Java scripts. In this case, the tools for data interfacing already provide the data loading and filtering processes. Hence, they are directly connected to the statistics module.

The statistics module is a common component working in the two paths. It basically calculates the indicators for the data quality in the multiple dimensions explained before. It accepts a DataFrame in order to make it interoperable, replicable and scalable; therefore, being able to calculate the data quality indicators independently of the source.

Data quality analysis results

As introduced, this paper presents the baseline results in terms of data quality for a set of buildings (pilots) across Europe. As extracted in Table 3, ten pilots from different European countries that are part of the EU DigiBUILD project, with different typologies and available datasets are analysed. Next sections describe the results for each one of these pilots in the various dimensions that are accounted in DigiBUILD.

Table 3: Pilot buildings within the EU DigiBUILD project for the data analysis

Pilot	Type	Datasets
UCL (UK)	University	Energy, photovoltaics, indoor air quality, occupancy, windows contact
EDF (France)	Offices	Indoor air quality, energy (heating, electricity and plugs)
IASI (Romania)	Various types	Indoor air quality, energy (heating and electricity)
VEOLIA (Spain)	Residential	Energy (district heating)
EMOT (Italy)	Offices	Energy, photovoltaics, charging station, electric vehicle, indoor air quality
FOCCHI (Italy)	Factory	Energy, photovoltaics, indoor air quality
HERON (Greece)	Various types	Energy, charging station, electrical vehicle
FVH (Finland)	Various types	Energy (district heating & heat pumps), photovoltaics
IEECP (The Netherlands)	Schools	Energy, indoor air quality, occupancy
NTUA (Greece)	University	Energy, indoor air quality, HVAC info

Accuracy

Starting with the accuracy dimension, The results show a dispersion of values, from 42.04% to 99%. In some cases, as for instance the UCL pilot, out- of-value ranges are due to changing needs of the heating/cooling systems. Other cases, malfunctioning of any sensor causes measurements out of range.

Table 4 summarizes the percentages obtained from a historical dataset sample of the aforementioned available datasets in the pilot building. For that end, minimum and maximum values for each data-point are obtained in order to reduce the range in 10%, being an acceptable value, such as stated by (Villada et al., 2008) and (Seyedzadeh et al., 2020). Then, values out of these range (known as expected) are considered anomalous.

The results show a dispersion of values, from 42.04% to 99%. In some cases, as for instance the UCL pilot, out-of-value ranges are due to changing needs of the heating/cooling systems. Other cases, malfunctioning of any sensor causes measurements out of range.

Table 4: Accuracy results of the data analysis

Pilot	Accuracy
UCL (UK)	70%
EDF (France)	44.43%
IASI (Romania)	n.a.
VEOLIA (Spain)	85%
EMOT (Italy)	56.18%
FOCCHI (Italy)	69.92%
HERON (Greece)	42.04%
FVH (Finland)	99%
IEECP (The Netherlands)	86.90%
NTUA (Greece)	55.69%

Completeness

Completeness aims the detection of data gaps in the timeseries. There are many cases where communication errors, malfunctioning of sensors or processing errors, among others, provoke data logging problems. Table 5 highlights the results of the analysis per pilot.

The results are diverse, remarking the case of EMOT, which is offering very low values (approximately 62% of data samples are missing). It should be considered the case of VEOLIA, with very high values, although this is not the reality. The reason behind lies in interpolation from the heat meter in a form of linear regression. The appearance is very complete data-set, but, with accurate populated values (e.g., boilers not working, but linear interpolation indicating energy consumption).

Figure 2: Monitoring stages

It is notable the maturity levels in the data collection. Pilots such as EDF or FVH with multiple years of data collection offers higher values with a very stable data gathering procedure. Less mature pilots are still in early stages where optimal operation is still not reached, as depicted in the monitoring stages in Figure 2 (Hernández et al., 2022).

Table 5: Completeness results of the data analysis

Pilot	Completeness
UCL (UK)	70%
EDF (France)	99.82%
IASI (Romania)	n.a.
VEOLIA (Spain)	99%
EMOT (Italy)	38.39%
FOCCHI (Italy)	~100%
HERON (Greece)	67.31%
FVH (Finland)	75.24%
IEECP (The Netherlands)	98.78%
NTUA (Greece)	99%

Reliability

The case of reliability focuses on the error-free data, without inconsistencies (accurate and complete). Then, its value is represented by the correlation between the completeness and accuracy, considering unique values from completeness (i.e., no data duplicates). Table 6 provides the results, where it is worth mentioning the case of EDF, in contrast to the completeness, lots of duplicates are removed, decreasing the reliability value.

Table 6: Reliability results of the data analysis

Pilot	Reliability
UCL (UK)	50%
EDF (France)	44.35
IASI (Romania)	n.a.
VEOLIA (Spain)	85%
EMOT (Italy)	21.57%
FOCCHI (Italy)	62.92%
HERON (Greece)	28.29%
FVH (Finland)	74.49%
IEECP (The Netherlands)	85.84%
NTUA (Greece)	55.63%

Consistency

Consistency relates to uniformity of data in terms of data behaviour. Considering data distribution follows a "normal" curve around the mean value, it is considered that data is consistent when a data-point complies with mean ± standard deviation. Table 7 illustrates the values for consistency. It should be taken the unexpected behaviour of the systems into account, such as the heating system. An example could be understood with COVID-19 situation, where energy demand increased, being a non-usual operation. Therefore, producing a deviation with respect to the “normal” distribution.

Table 7: Consistency results of the data analysis

Pilot	Consistency
UCL (UK)	70%
EDF (France)	34.11%
IASI (Romania)	n.a.
VEOLIA (Spain)	79%
EMOT (Italy)	32.97%
FOCCHI (Italy)	71.83%
HERON (Greece)	88.60%
FVH (Finland)	~99%
IEECP (The Netherlands)	82.14%
NTUA (Greece)	86.53%

Consistency is also addressed by a Smart Contract in charge of the notarization of data. A Proof of Existence (PoE) algorithm is developed, based on blockchain, to calculate the hash on the data provider side, as well as on the data storage side (see Figure 3). By comparing the hashes, the consistency in both sides can be obtained (i.e., detection of communication errors or data manipulation).

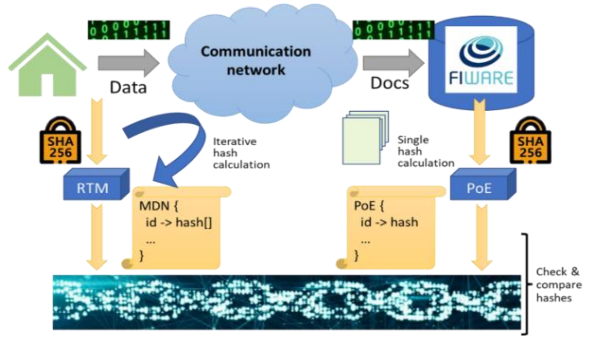

Figure 3: Proof of Existence concept

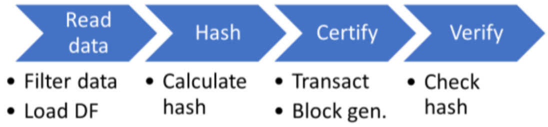
Figure 4 depicts the process, which has been applied within VEOLIA case. From the real data read, a data-set is filtered and loaded as a DataFrame, whose hash is calculated to be sent to the blockchain as a transaction and, thus, certify data. In the verification step, the received data is hashed and compared to the original hash (see Figure 4). The result of the transaction is shown below, where the output from the blockchain is generated, indicating the hash of the transaction and the block that has been generated.



AttributeDict({'args': AttributeDict({'': AttributeDict({'description': 'data from VEOLIA', 'provider': '0xb8f356ab125212CCd7017D8766B0463B531bA137', 'timestamp': 1700053800})}), 'event': 'Notarized', 'logIndex': 0, 'transactionIndex': 0, 'transactionHash': HexBytes('0x0310cf7829b8a11414ce1306acf6fe0dd8acd3908a13a9b2ce825bab40436c11'), 'address': '0x8a442905884c6a62938a77600aAeC7c9a073AAD7', 'blockHash': HexBytes('0x8548aabb4683617de8c49551b9f3a49ed36c94780a6baeea1f2d10cc9cd6717e'), 'blockNumber': 3641})

Figure 4: Consistency check from Smart Contract

Relevance

The relevance dimension focuses on the end-user and the usability of data. Nowadays, monitoring systems and digitalization have exponentially grown, obtaining bigger amounts of data without real usability in services or decision-making. That is why relevance plays an important role in DigiBUILD, determining the real usable datasets to provide high-level services. Table 8 specifies the percentage of datasets that are relevant for the DigiBUILD services and, thus, useful in this context.

Table 8: Relevance results of the data analysis

Pilot	Relevance
UCL (UK)	35.54%
EDF (France)	28%
IASI (Romania)	37.5%
VEOLIA (Spain)	55.73%
EMOT (Italy)	100%
FOCCHI (Italy)	55.73%
HERON (Greece)	100%
FVH (Finland)	30%
IEECP (The Netherlands)	n.a.
NTUA (Greece)	n.a.

Accessibility

Data, even with quality enough and relevant, sometimes is not accessible due to proprietary protocols. Accessibility determines the ability of remotely capture data and make it available for services and decision-making procedures. In this sense, Table 9 compiles the percentage of datasets that are accessible from pilot buildings. In some cases, although interfaces for access are being configured, these are not fully available; therefore, limiting the accessibility to data.

Table 9: *Accessibility results of the data analysis*

Pilot	Accessibility
UCL (UK)	50%
EDF (France)	50%
IASI (Romania)	n.a.
VEOLIA (Spain)	100%
EMOT (Italy)	80%
FOCCHI (Italy)	50%
HERON (Greece)	80%
FVH (Finland)	80%
IEECP (The Netherlands)	70%
NTUA (Greece)	80%

Timeliness

Last dimension in DigiBUILD is timeliness, responsible for setting the time when data is made available, which relates to the "real-time" operation. Some samples are obtained in 5 min periodicity, while others are in 15 minutes or even 1 hour, as specified in Table 10. Here, the event-driven data collection (in other words, change of value) is not considered, although it exists.

Discussion

Data quality is crucial to make decisions, such as improvement in the energy management of buildings, retrofitting investments or air quality enhancement. This is not always covered and decisions are made based on low quality data. Within DigiBUILD a methodology to check datasets quality, incorporating the improvement, is proposed. At this first stage, the initial data analysis has been performed to determine the baseline.

What is clearly remarkable is the maturity level and the age of the building. According to Figure 2, depending on the monitoring stage, optimal operation in the data collection can be achieved, as the cases of VEOLIA, IEECP or FVH pilots, with very high level of maturity; therefore, high-quality of data. Others, such as IASI pilot is still in the interventions stage, without providing data (0% in the indicators), as depicted in Figure 5. The age of the building is also important. New buildings, such as the UCL pilot with only 1 year old, contain smarter technology with capabilities of data storage and access.

To sum up, it is undoubtedly data quality is a pivotal aspect in the decision-making process and this aspect should be carefully treated. As observed in Figure 5, there exists a diversity of maturity levels with a clear room for improvement. The graph is only showing a subset of dimensions (the most relevant ones). Availability and accessibility of data must be ensured. Data processing for data filtering and cleansing is a very important task that would improve the current data quality.

Table 10: *Timeliness results of the data analysis*

Pilot	Timeliness
UCL (UK)	5/15 min
EDF (France)	5/10 min
IASI (Romania)	n.a.
VEOLIA (Spain)	15 min
EMOT (Italy)	3 min
FOCCHI (Italy)	1 hour
HERON (Greece)	30 sec
FVH (Finland)	10 min
IEECP (The Netherlands)	30 min
NTUA (Greece)	5 min

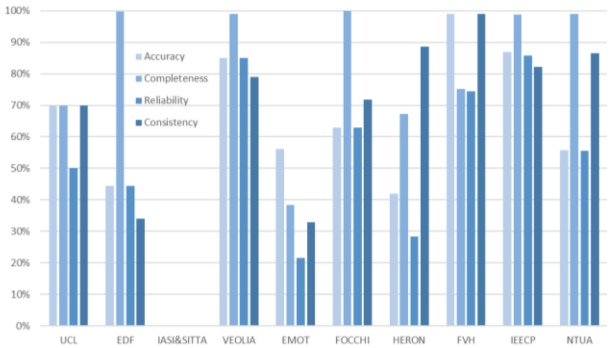


Figure 5: Data quality indicators per pilot building

Conclusions

This paper has described a data analysis carried out under the umbrella of the European DigiBUILD project to determine the baseline in terms of data quality for decision-making. From historical data samples in 9 different countries across Europe, 7 dimensions have been considered within the data analysis. The results provide an overview of the real maturity levels within the digitalization and data collection of the building stock.

Different levels of maturity could be observed, from pilots that already are in the optimal operation stage; then, obtaining high-values for the different data quality dimensions to other in very early stages, decreasing the trustworthiness on data. This deals with two issues. First of all, making decisions based on low-quality data; hence, increasing the uncertainty. Secondly, decision-makers are reluctant when addressing an energy efficiency project. In this sense, data quality checks are crucial.

A data analysis has been performed to check the data quality levels of multiple datasets. Due to the capability for improvement of the quality, the methodology is extended with correction techniques. At the current state of the project, they have not been fully implemented and it is the future work. The aim is to increase data quality and reach the outcomes that were previously explained.

Acknowledgments

The authors would like to thank DigiBUILD consortium and European Commission for funding the project under GA#101069658 of the Horizon Europe programme.

Abstract

Lightweight bridges are subjected to moving loads (vehicular traffic), with vehicular masses typically being comparable to structural masses. Moving loads are thus regarded as "traveling masses", resulting in complex dynamic behavior, which is hardly covered by conventional damage detection strategies. This paper presents a concept towards damage detection in lightweight bridges with traveling masses using machine learning (ML). Specifically, a ML model for classifying structural damage is trained, using simulations, and applied using real-world structural response data. Preliminary tests of the proposed concept validate the power of the ML model in identifying structural damage, despite the non-stationarity of the problem.

Introduction

Research on advancing material technologies to develop high-strength materials has been conducted since the second half of the 20th century (Flaga, 2000). The construction industry has been increasingly leveraging high-strength materials in an attempt to meet structural design requirements while reducing material usage (Zhang et al., 2019). Furthermore, in bridge design and construction, practitioners frequently seek to reduce the size of structural elements, which, apart from the obvious financial benefit, also helps meet practical and aesthetical requirements.

High-strength materials, however, frequently result in lightweight flexible structures, which are prone to heavy oscillations. A notable example is the case of the Millennium Bridge in London, which exhibited large oscillations, due to the large crowds drawn during opening in 2000 (Dallard et al., 2001). Consequently, material reduction in bridges requires care to avoid unanticipated oscillations. Moreover, placing the discussion on bridge oscillations under operational conditions, bridges are expected to withstand oscillations induced by operational loads, such as vehicular traffic.

At a first glance, the problem of vehicles traversing bridge decks may be described as a "moving load" problem, the dynamics of which differ from conventional structural dynamics, in that the structural response is affected by the velocity of the vehicles (Firus, 2023). In lightweight bridges, however, vehicular masses may be comparable to structural masses (particularly in railway bridges) and are regarded as "traveling masses", resulting in a complex non-stationary problem. With respect to damage detection, which is the focal point of structural maintenance, conventional damage detection strategies hardly address the traveling-mass problem. Experimental techniques as well as structural health monitoring (SHM) strategies typically rely on data analysis methods suitable for stationary problems, e.g. identifying the frequency content of structural response data using the Fourier transform (Dragos et al., 2024). Studies on moving loads on beams also fail to capture the damage-detection traveling-mass problem in its totality.

Approaches describing the dynamic response of beam structures under traveling masses have been widespread in literature. Examples range from as far back as the late 1990s, with the work of Siddiqui et al. (1998) who investigated the motion of a cantilever Euler-Bernoulli beam under the effect of a moving mass-spring system, to recent works, such as the approach reported by Meher et al. (2019), who have used Green's function to describe the response of a beam traversed by a traveling mass. Furthermore, the vibration control of beams, considering vehicle-bridge interaction, has been investigated by Pi & Ouyang (2016), and the critical speed of a traveling mass, affecting the behavior of the coupled mass-beam system, has been the focus of work by Dehestani et al. (2009). A recent work, reported by Abu-Alshaikh et al. (2020), has focused on obtaining analytical responses of a functionally graded beam with a traveling mass using Caputo-Fabrizio fractional derivative models.

Nevertheless, damage detection on beams with traveling masses has received scarce attention. An early approach has been proposed by Billelo & Bergman (2004), basing damage detection on comparing the displacement histories obtained from an intact bridge model before and after inducing damage. In recent work, Cicirello (2019) has studied the response bounds of Euler-Bernoulli beams with structural damage from a theoretical standpoint. Moreover, Zhan et al. (2021), have used wavelet transform coefficients of experimentally derived modal parameters for indirect damage detection. Despite the solid background offered by the aforementioned approaches, damage detection relies on either displacement measurements, which, although frequently used in experimental techniques, are uncommon in state-of-the-art SHM systems employed for structural maintenance, or on the accuracy of experimentally derived modal parameters, which is hardly guaranteed in non-stationary problems. As a result, damage detection on beams with traveling masses stands to benefit from an approach compatible with measurements typically collected in modern SHM systems (e.g. acceleration response data) and with state-of-the-art computational tools.

The non-stationarity of the traveling-mass problem calls for advanced data analysis methods, drawing from the field of artificial intelligence and its subset machine learning (ML), which has been employed in civil engineering applications, such as in fault diagnosis of SHM systems (Al-Zuriqat et al., 2023). In this direction, this paper presents a concept for damage detection on lightweight bridges with traveling masses, using a ML model for classifying acceleration response data into structural damage scenarios. The reasoning behind using ML is that damage patterns manifested in acceleration response data may be either too subtle to discern or obscured in frequency-domain representations of the data, due to the non-stationarity of the problem. The ML classification model, used in this study, is a convolutional neural network (CNN), which is trained with "labeled" acceleration response data, i.e. data corresponding to predefined structural condition scenarios, obtained from simulations using a well-calibrated analytical model. Upon completing training, classification is performed using real-world acceleration response data. The proposed concept is validated in preliminary laboratory tests, showcasing the capability of the CNN in identifying structural damage, as represented by partial loss of fixity at one support of a steel beam. The remainder of the paper includes a presentation of the concept, followed by the validation tests. The paper ends with a summary and conclusions and an outlook on future research.

Damage detection in lightweight bridges with traveling masses

The cornerstone of the proposed concept is the coupling between analytical modeling and simulation with ML. It is therefore clear that creating a well-calibrated analytical model for producing the acceleration response data for training the CNN is particularly important. As such, the description of the concept in this section starts with a brief discussion on the analytical modeling and simulation method employed for producing acceleration response data, followed by a presentation of the CNN training, including the preprocessing of the acceleration response data and the functionality of the CNN.

Analytical modeling of the traveling-mass problem

In its simplest form, a lightweight bridge with a traveling mass can be modeled as a continuous Euler-Bernoulli beam, as shown in Figure 1. The equation of motion of the beam accounts for inertia forces both of the vibrating beam and of the travelling mass (Dadoulis & Manolis, 2023):

$$\rho A\ddot{w}(x,t)+c\dot{w}(x,t)+EIw''''(x,t)=f_c\delta\left(x-|v|t\right). \quad (1)$$

In Equation (1), ρ is the material density, A is the cross-section area of the beam, E is the modulus of elasticity, I is the moment of inertia of the beam in the vertical direction, c is the damping coefficient, w is the vertical displacement of the neutral axis of the beam, δ is the Dirac delta, x represents the spatial coordinate in the longitudinal direction of the beam, and t is time. The functional $f_c > 0$ represents the contact force between the traveling mass and the beam, and $|v|$ is the speed of the traveling mass. Finally, $\dot{w} = \partial w/\partial t$, $\ddot{w} = \partial^2 w/\partial t^2$, and $w'''' = \partial^4 w/\partial x^4$.

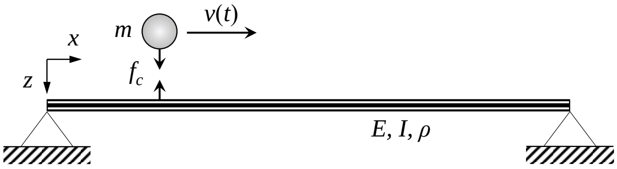

Figure 1: Bernoulli-Euler beam with traveling mass.

From Equation (1), it is evident that the factor that differentiates the traveling-mass problem from a regular Euler-Bernoulli-beam equation of motion is the contact force f_c. To estimate f_c, the equilibrium at the contact point of the traveling mass with the beam is considered. First, the static equilibrium is expressed as the total vertical displacement w_T, which is a summation of the vertical displacement of the beam and a component representing the surface roughness $r(x) = r(|v|t)$:

$$w_T\left(|v|t,t\right)=w\left(|v|t,t\right)+r\left(|v|t\right). \quad (2)$$

Furthermore, the dynamic equilibrium is provided by the following expression:

$$m\ddot{w}_T\left(|v|t,t\right)=mg-f_c, \quad (3)$$

where g is the gravitational acceleration. By solving Equations (2) and (3) with respect to f_c and by substituting f_c into Equation (1), the equation of motion is converted into:

$$\rho A\ddot{w}+c\dot{w}+EIw''''=m\left[g-\frac{d^2w}{dt^2}-\frac{d^2r}{dt^2}\right]\delta\left(x-|v|t\right). \quad (4)$$

In Equation (4), the time and spatial coordinate of w have been dropped for simplicity. It is noted that the right-hand side of Equation (4) includes total derivatives, which are expanded as follows:

$$\frac{d^2w}{dt^2}=\frac{\partial^2 w}{\partial t^2}+2v\frac{\partial^2 w}{\partial x\partial t}+v^2\frac{\partial^2 w}{\partial x^2}, \quad (5)$$

$$\frac{d^2r(x)}{dt^2}=\frac{\partial^2 r}{\partial x^2}\left(\frac{dx}{dt}\right)^2=v^2\frac{\partial^2 r}{\partial x^2}. \quad (6)$$

In Equation (5), the second term corresponds to the Coriolis acceleration, and the third term is the centrifugal acceleration, which is irrelevant to the problem being studied and is therefore neglected. Using Equations (5) and (6), Equation (4) becomes:

$$\rho A\ddot{w} + c\dot{w} + EIw'''' = m\left[g - \ddot{w} - 2v\dot{w}' - v^2 r''\right]\delta(u) \\ u = x - vt. \tag{7}$$

Equation (7) is solved via modal analysis, for which the vertical displacement is analyzed into a spatial component and a temporal component:

$$w(x,t) = \varphi_n(x)q_n(t), \qquad n = 1,2,...,p\,, \tag{8}$$

where $\varphi_n(x)$ is nth "eigenfunction", representing the mode of vibration in the form of a wave function, and $q_n(t)$ is the nth "generalized" coordinate function, which characterizes the temporal variation of the vibration. From Equation (8), it is clear that the complexity of the solution depends on the number of eigenfunctions (p) considered. For regular structures in structural dynamics, it is common to consider only a few eigenfunctions, which are capable of capturing the structural dynamic behavior. The nth eigenfunction is given by:

$$\varphi_n(x) = C_n \sin\left(\frac{n\pi x}{L}\right), \tag{9}$$

where L is the beam length, and C_n is a constant related to the boundary conditions of the beam. Eigenfunctions follow the orthogonality condition:

$$\rho A\int_0^L \varphi_i(x)\varphi_j(x)dx = \delta_{ij}\,, \tag{10}$$

where δ_{ij} is the Kronecker delta. As a result, by substituting Equation (8) into Equation (7) for p eigenfunctions arranged in vector format $w = \boldsymbol{\varphi}(x)\mathbf{q}(t)$, ($\boldsymbol{\varphi}(x) = [\varphi_1(x),\varphi_2(x),\ldots,\varphi_p(x)]$, $\mathbf{q}(t) = [q_1(t),q_2(t),\ldots,q_p(t)]^T$), pre-multiplying with $\boldsymbol{\varphi}(x)^T$, integrating over L, and exploiting the Dirac delta property:

$$\int_0^L \varphi(x)\delta(x - vt)dx = \varphi(vt), \tag{11}$$

proven in Dadoulis & Manolis (2022), the equation of motion is recast into a $p\times p$ system of differential equations of the following format:

$$\begin{aligned} &\mathbf{M}(t)\ddot{\mathbf{q}}(t) + \mathbf{C}(t)\dot{\mathbf{q}}(t) + \mathbf{K}(t)\mathbf{q}(t) = \mathbf{F}(t) \\ &\mathbf{M}(t) = \mathbf{I} + m\boldsymbol{\varphi}\boldsymbol{\varphi}^T \\ &\mathbf{C}(t) = diag(2\xi_n\omega_n) + 2mv\boldsymbol{\varphi}\boldsymbol{\varphi}'^T \\ &\mathbf{K}(t) = diag(\omega_n^2) + mv^2\boldsymbol{\varphi}\boldsymbol{\varphi}''^T \\ &\mathbf{F}(t) = mg\boldsymbol{\varphi} - mv^2 r''(x(t))\boldsymbol{\varphi}. \end{aligned} \tag{12}$$

In Equation (12), ξ_n is the critical damping ratio of the nth eigenfunction, and ω_n is the respective natural frequency, computed as follows:

$$\xi_n = \frac{c}{2\rho AL\omega_n} \qquad \omega_n = \frac{n^2\pi^2}{L^2}\sqrt{\frac{EI}{\rho A}}. \tag{13}$$

For producing the structural response to the traveling-mass problem, the generalized coordinate functions $\mathbf{q}(t)$ need to be computed. To this end, Equation (12), which represents a set of ordinary differential equations of second order, is converted into a set of first-order ordinary differential equations, using the state-space formulation:

$$\dot{\mathbf{y}}(t) = \left[-\mathbf{A}^{-1}(t)\mathbf{B}(t)\right]\mathbf{y}(t) + \mathbf{A}^{-1}(t)\mathbf{h}(t)\,. \tag{14}$$

The notations in Equation (14) are explained as follows:

$$\mathbf{A}(t) = \begin{bmatrix} \mathbf{0} & \mathbf{M}(t) \\ \mathbf{M}(t) & \mathbf{C}(t) \end{bmatrix}, \ \mathbf{B}(t) = \begin{bmatrix} -\mathbf{M}(t) & \mathbf{0} \\ \mathbf{0} & \mathbf{K}(t) \end{bmatrix} \\ \dot{\mathbf{y}}(t) = \begin{bmatrix} \dot{\mathbf{q}}(t) \\ \mathbf{q}(t) \end{bmatrix}, \quad \mathbf{h}(t) = \begin{bmatrix} \mathbf{0} \\ \mathbf{F}(t) \end{bmatrix}. \tag{15}$$

Assuming discrete time, Equation (14) is solved for every time instance k by performing eigenvalue analysis to matrix $(-\mathbf{A}_k)^{-1}\mathbf{B}_k$, which is non-symmetric and yields a matrix of complex eigenvalues $\boldsymbol{\Lambda}_k$ and eigenvectors matrix $\boldsymbol{\Psi}$. The eigenvalues matrix is given by:

$$\boldsymbol{\Lambda}_k = diag(\boldsymbol{\lambda}_{n,k}), \ \boldsymbol{\lambda}_{n,k} = \begin{bmatrix} e^{\lambda_{n,k}} & 0 \\ 0 & e^{\bar{\lambda}_{n,k}} \end{bmatrix}, \\ \lambda_{n,k} = \xi_{n,k}\omega_{n,k} \pm i\omega_{n,k}\sqrt{1 - \xi_{n,k}^2}\,, \quad \xi_{n,k} \neq \xi_n. \tag{16}$$

Using Equation (16), the solution of Equation (14) at time instance k is:

$$\mathbf{y}_k = \boldsymbol{\Theta}_k(\boldsymbol{\Theta}_{k-1})^{-1}\mathbf{y}_{k-1} + \boldsymbol{\Theta}_k\int_{k-1}^{k}(\boldsymbol{\Theta}_s)^{-1}\mathbf{A}_k^{-1}\mathbf{h}_k ds \\ \boldsymbol{\Theta}_k = \boldsymbol{\Psi}_k\boldsymbol{\Lambda}_k. \tag{17}$$

The generalized coordinate functions are used together with the eigenfunctions to reconstruct the vertical displacement functions $w(x,t)$ using Equation (8). In turn, the vertical displacement functions are used as to produce the acceleration response data using Equation (14) (hereinafter termed "simulation data"), which are processed to be used for training the CNN.

Training of a convolutional neural network for damage detection

In theory, the simulation data could be used "as is" (i.e. in time-history format) as input to the CNN, since simulation data is relatively "clean" from noise and random components. However, upon completing training, the

CNN is expected to be applicable with real-world acceleration response data, in which the presence of spurious factors, such as noise and random components, is likely. As argued in Fritz et al. (2022), to reduce the effect of spurious factors and expose features in the simulation data, data preprocessing is necessary. Considering the non-stationarity of the traveling-mass problem, common preprocessing methods, producing fixed-window frequency-domain representations are hardly informative. Instead, preprocessing that depicts the coupled time-frequency content of the simulation data is necessary. Furthermore, as evidenced in Equation (14), the eigenvalues of the coupled traveling-mass-beam system change at every time instance *k*. As a result, a preprocessing method that enables tracking the evolution of eigenvalues is used, namely the Gabor transform (Qian & Chen, 1993):

$$G_w\left(\kappa\right) = S\left[\sum_{j=1}^{N} \ddot{w}\left(x,t_j\right) z_j e^{-i2\pi\kappa j / N}\right]^2, \kappa = \frac{N \cdot f}{f_s}. \quad (18)$$

In Equation (18), G_w is the Gabor coefficient, κ is the index of the discrete frequency bin of frequency f, considering a discrete set of simulation data of length N, sampled at frequency f_s ($f_s = 1/\Delta t$). The "Gabor" window function is denoted as z_j and could be any window function, such as the Gaussian function or the Hann window. Finally, S is a scaling factor.

Gabor coefficients are typically illustrated as colormap images. An exemplary illustration of a Gabor-transform image of simulation data representing acceleration of an Euler-Bernoulli beam is given in Figure 2.

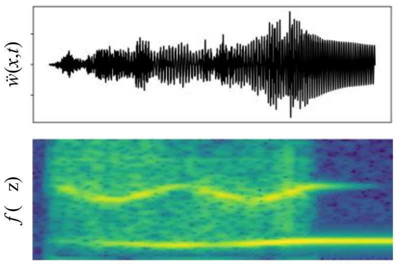

Figure 2: Gabor transform depiction of simulation data.

Upon producing the Gabor transform images, the damage detection problem is reduced to a classification problem, which is solved by the CNN. As shown Figure 3, a typical CNN consists of one *input* layer, a succession of *convolution* layers and *pooling* layers, (at least) one *fully-connected* layer, one *dropout* layer, and one *output* (classification) layer. Each Gabor transform image is passed in red-green-blue (RGB) format of size $N_I \times N_I \times 3$ from the input layer to the first convolution layer. Thereupon, the image is subjected to feature extraction, performed by progressively "sliding" square matrix "kernels" of size $n_I \times n_I \times 3$ (generally, $n_I << N_I$) over the image and by convolving RGB values of image areas (of dimensions matching the kernel size) with the kernel matrix elements. The outcome of each convolution layer is a so-called "feature map", consisting of convolutional products, and each product is fed to an activation function, which introduces non-linearity to the CNN, necessary for solving non-trivial problems. The outcomes of the activation function ("activations") are propagated to the pooling layer, which applies a sliding-window operation on the activations, typically computing either the average of each sliding window or the maximum value, to reduce the dimensionality of the activations. The last pooling layer is succeeded by a fully-connected layer, which comprises neurons connected to every outcome of the pooling layer. The fully-connected layer is followed by a dropout layer, in which a predefined percentage of features are "dropped" (i.e. ignored) to prevent overfitting. Finally, the dropout layer is connected to the output layer, which holds the classes.

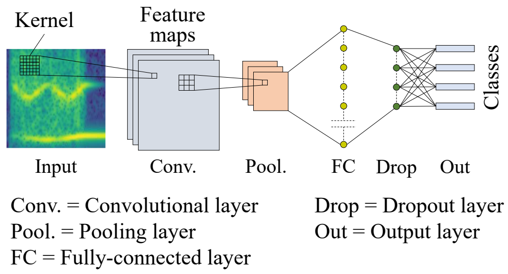

Figure 3: Layout of a typical CNN.

To perform classification, the CNN is trained, i.e. the kernels are fine-tuned so that the prediction accuracy of the output layer exceeds a predefined threshold. The training is performed using a "labeled" set of Gabor transform images, i.e. images that correspond to known structural conditions, including images from the intact structure as well as images from damage scenarios, simulated via changing values of structural parameters of the analytical model, resulting in stiffness reduction equivalent to reduction caused by damage. The labeled set is divided into a training set (70% of the images), a validation set (20% of the images), and a testing set (10% of the images). The training set is propagated sequentially (in "batches") through the CNN, and the prediction error gradient, obtained from the output layer is back-propagated to update the kernels using an optimization algorithm, such as gradient descent, and a learning rate, which controls the fine-tuning rate of the kernels. Each cycle of propagation and back-propagation of a batch is a training iteration, and once all the images in the training set are used, one epoch is completed. The validation set is passed through the CNN periodically during training, after a predefined number of iterations. The purpose of validation is to monitor the prediction accuracy improvement of the CNN with an independent set of images so as to avoid overfitting the CNN to the training set. The testing set is passed through the CNN at the end of training, i.e. upon achieving the predefined prediction accuracy, to check the CNN performance.

A proof-of-concept implementation and validation of the proposed concept, including the analytical modeling of a beam structure, the data preprocessing and the training of a CNN for damage classification are presented in the next section.

Implementation and validation

The prototype implementation and validation of the proposed concept involve defining software tools for simulations and CNN training, as well as devising a laboratory proof-of-concept test. In this section, first the implementation is discussed, followed by the presentation of the validation test and a discussion of the results.

Implementation

The first part of the implementation consists in developing an algorithm for analytical modeling and data pre-processing, based on Equations (1)-(18). The algorithm is written in the Python programming language and consists of functions *model_setup*, *eig_decomp* and *state_space_comp*, dedicated to (i) computing the matrices **A** and **B** for every time instance k, (ii) performing eigenvalue analysis to matrix $(-\mathbf{A}_k)^{-1}\mathbf{B}_k$, and (iii) to applying Equation (17) to compute the vector $\mathbf{y}_k$, respectively. A separate function, *data_gen*, is written to retrieve the displacement histories, using the eigenfunctions, and to compute the acceleration response data using Equation (14). Finally, the Gabor transform is realized by function *gaborTrsf*, and the corresponding images are produced.

The second part of the implementation involves developing and training the CNN. Since, only a proof-of-concept study is shown, an elaborate parametric analysis of the CNN performance and an optimal definition of the CNN architecture fall beyond the scope of this paper and will be investigated in future research. Instead, the MATLAB deep learning tool is leveraged, and a simple CNN architecture is devised, shown in Figure 4, adjusted to the input of Gabor transform images and to the number of classes being considered.

Validation tests

The laboratory validation test is devised on a simply supported HEB100 steel beam, representing a downscaled model of a lightweight bridge traversed by a traveling mass, shown in Figure 5. The cross section of the beam has dimensions 100×100×10×6 (mm) (width × height × flange thickness × web thickness). The total length of the neutral axis of the beam is 5830 mm. The beam is part of an experimental setup, which includes adjustable struts that ensure that the beam is level. It is noted that the beam is supported only at its ends, i.e. the struts are not used as supports to the beam. The experimental setup also consists of pulleys that enable masses to move along the longitudinal axis of the beam and a motor that controls the mass speed.

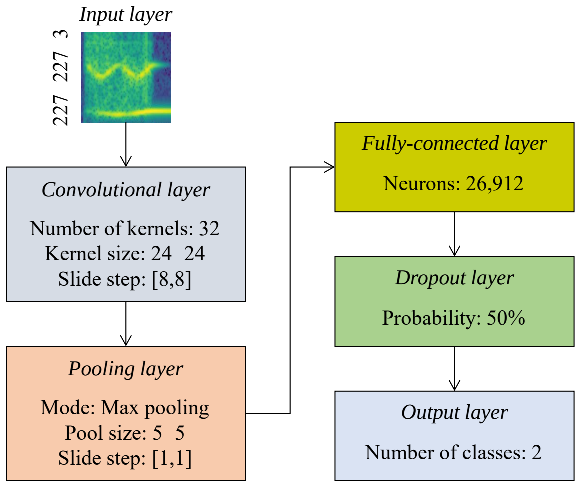

Figure 4: The CNN architecture defined in this study.

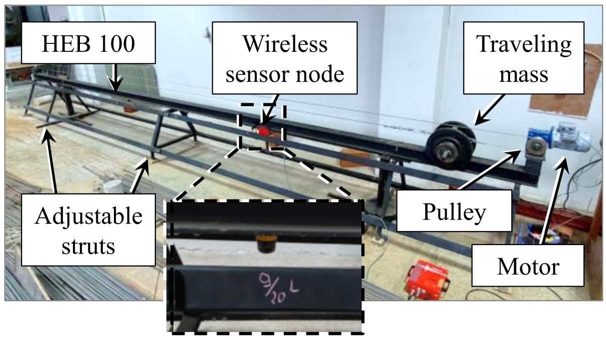

Figure 5: Experimental setup.

An analytical model of the beam is developed and used for simulating the motion of a traveling mass across the beam. The modulus of elasticity and the material density are computed via preliminary laboratory tests as $E = 198.5$ GPa and $\rho = 7.65 \cdot 10^3$ kg/m^3, respectively. To produce a labeled set covering a sufficient part of the available solutions space, the mass value and speed are randomly perturbed to devise several simulation scenarios. Specifically, the mass (m) assumes values between 10 kg and 40 kg, and the speed ($|v|$) assumes values between 0.2 m/s and 0.5 m/s. With respect to the structural condition, two structural “states” are considered, one for the intact beam and one assuming loss of fixity at one support, i.e. by substituting the vertical support with a translational spring, resembling erosion of foundation subsoil, e.g. as a result of scour. A total of 500 simulations are conducted for each state, computing acceleration response data at a distance equal to 9L/20 from the beam end and at a sampling frequency of $f_s = 128$ Hz. The reasoning behind avoiding the midspan of the beam is that the second eigenfunction, which contributes to the structural response, is characterized by an antisymmetric sinusoidal shape with a zero-crossing point at the midspan. Hence, collecting acceleration response data from the midspan would underestimate the contribution of the second eigenfunction. In turn, 500 Gabor transform images per class are produced, forming the labeled set used for training the CNN. Exemplary illustrations of Gabor transform images for both states are given in Figures 6 and 7. The variation of the first two eigenfrequencies is marked for both structural states considered, as a result of the variable structural dynamic properties of the beam due to the motion of the mass. As can be seen in the figures, the loss of fixity at the support reduces the eigenfrequencies; however, the variation trend is similar in both states.

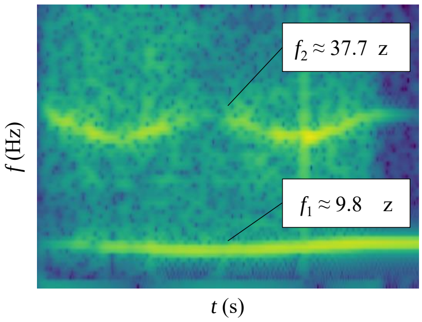

Figure 6: Gabor transform for the intact beam (m = 23.3 kg, $|v|$ = 0.351 m/s).

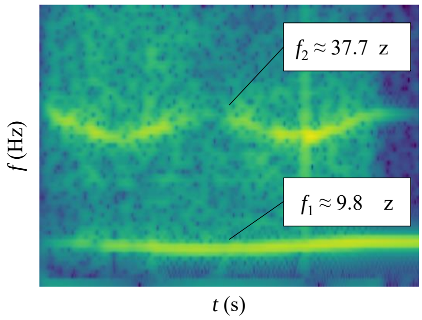

Figure 7: Gabor transform for the damaged beam (m = 15 kg, $|v|$ = 0.46 m/s).

The training of the CNN is performed by first splitting the labeled set into 70% training set (350 images), 20% validation set (100 images), and 10% testing set (50 images). During training, the "Adam" optimizer – a stochastic gradient-descent optimization algorithm – is employed for fine-tuning the kernels in each iteration (Kingma & Ba, 2015). The initial learning rate is set to 0.001, the batch size is 30 images, and the validation frequency is defined at every 30 iterations. The total number of epochs is set equal to 10, and the learning rate is reduced at every epoch by a factor of 0.5. A high training accuracy of 98% is achieved after 122 iterations, and the accuracy of the validation set reaches 100% after 30 iterations, as shown in Figure 8.

Prior to applying the CNN with acceleration response data from the experimental setup, the classification capability of the CNN is verified using the testing set. The classification test results are given in the form of a "confusion" matrix, shown in Table 1.

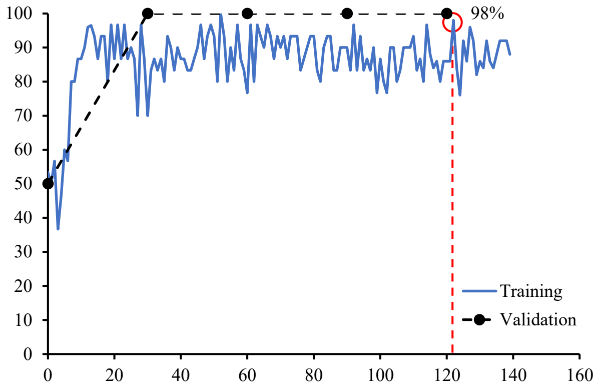

Figure 8: Training and validation accuracy history.

Table 1: Confusion matrix for the testing data set.

	Intact	Damaged
Intact	50	0
Damaged	0	50

The results for the testing dataset corroborate the training accuracy, since every image of the testing dataset has been correctly classified. The next step of the validation test involves using the CNN for classifying Gabor transform images produced from real-world acceleration response data obtained from the experimental setup. The data is collected using a Lord Microstrain G-Link-200 wireless sensor node capable of measuring acceleration in 3 axes at ranges up to ±8g and at sampling frequencies up to 4,096 Hz (Microstrain Sensing, 2020). Experiments are conducted for two structural states, matching the states used in the simulations, using 30 combinations of mass and speed values per state, as listed in Table 2.

Table 2: Combinations of mass and speed values for the laboratory experiments.

Nr.	Mass m (kg)	Speed $|v|$ (m/s)	Nr.	Mass m (kg)	Speed $|v|$ (m/s)
1	13	0.25	16	27	0.40
2	13	0.30	17	27	0.45
3	13	0.35	18	27	0.50
4	13	0.40	19	18	0.25
5	13	0.45	20	18	0.30
6	13	0.50	21	18	0.35
7	23	0.25	22	18	0.40
8	23	0.30	23	18	0.45
9	23	0.35	24	18	0.50
10	23	0.40	25	38	0.25
11	23	0.45	26	38	0.30
12	23	0.50	27	38	0.35
13	27	0.25	28	38	0.40
14	27	0.30	29	38	0.45
15	27	0.35	30	38	0.50

The loss of fixity is realized by placing a spring between the beam end and its support. Acceleration response data is collected for every experiment close to the midspan of the beam, at a point located at $9L/20$ from the beam end, as shown in Figure 5, at a sampling frequency of $f_s = 128$ Hz, as in the simulations. The acceleration response data from each experiment is used to produce a Gabor transform image, resulting in a set of 60 Gabor transform images to be fed to the CNN, an example of which is shown in Figure 9.

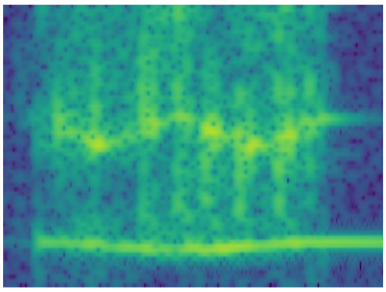

Figure 9: Gabor transform for experiment 10 (intact beam).

The similarity between Figure 9 and Figures 6 and 7 is indicative of the satisfactory proximity between the analytical model and the experimental setup. The Gabor transform images are fed to the CNN and classified into the two classes, corresponding to the states considered. The results are summarized in the following confusion matrix:

Table 3: Confusion matrix for the experiments.

	Intact	Damaged
Intact	30	0
Damaged	1	29

The results of the experiments clearly highlight the capability of the CNN to correctly classify real-world acceleration response data. From the Gabor transform images of the intact beam, only one experiment is misclassified as “damaged”, while the respective images of the damaged beam are all correctly classified. Furthermore, the results serve as proof of the validity of the proposed concept and of the “transferability” of the CNN training from the domain of simulations to the real world.

Summary and conclusions

Damage detection on lightweight bridges with traveling masses is a non-stationary problem that is hardly covered by conventional methods, developed for experimental testing or structural health monitoring. In this context, this paper has presented a concept towards detecting damage on lightweight bridges, represented by Euler-Bernoulli beams. The proposed concept is based on analyzing the behavior of the beam using analytical modeling for a set of predefined damage scenarios and on using simulation-derived acceleration response data to train a convolutional neural network to classify the data into the damage scenarios. Thereupon, the convolutional neural network is applied using real-world acceleration response data.

The proposed concept has been validated in a proof-of-concept laboratory test on a steel beam with a traveling mass, representing a downscaled model of a lightweight bridge. The results have shown that the convolutional neural network (i) can be trained with high accuracy using simulation-derived acceleration response data and (ii) can be transferred to real-world applications, assuming adequate calibration of the analytical model. Future work may focus on considering several damage scenarios, anticipated to occur over the lifetime of lightweight bridges, as well as on developing the proposed concept into a structural health monitoring approach.

Abstract

Feature extraction on façades from unstructured point clouds is a challenging work, especially in the presence of noise. Previous studies in reconstructing the building façade are limited to traditional urban buildings. However, facade with a big proportion of windows, like curtain wall, are less explored. This research aims to propose an automatic approach to extract building features of a facade with a big proportion of windows, such as curtain wall. This approach includes automated detection of the facades, openings detection and geometry information extraction. A real case is used for testing the framework and validating the effectiveness of the approach.

Introduction

Building façades are highly related to energy consumption. Energy-efficient retrofitting of existing buildings is a key aspect of reaching the energy consumption reduction targets fixed by public authorities in different countries (Previtali et al., 2014; Sun et al., 2019). Europe has numerous historic and old buildings that face challenges, such as energy loss and higher operational costs, and need to be more energy efficient (Massafra et al., 2022). The geometry information of facades is crucial for the energy simulation.

Recent developments in generating digital twins (DTs) of buildings and point cloud techniques have the potential to obtain the geometry of building façades and improve its efficiency and accuracy (Pan et al., 2023). Geometric building models can be created based on point cloud acquisition and processing techniques (Pan et al., 2022; Wang et al., 2020). However, obtaining 3D information of façades from point cloud of existing buildings is still a challenging and costly process (Wang et al., 2022).

Previous studies in reconstructing the building façade and their openings are limited to specific types of buildings, mainly urban traditional buildings. These building facades are typically composed of concrete or brick blocks with low reflectance materials. Building façades with high reflectance materials were not considered in previous studies.

This research aims to propose an automatic approach to extract building features of a facade with a big proportion of windows, such as curtain wall. The proposed framework includes automated detection of the facades and glass windows from the building's point cloud using emerging image processing technologies techniques. Specifically, the geometric information of the recognised windows could be automatically extracted from the point clouds. Compared with previous approaches, the approach proposed in this research could be more feasible for building façades with a big proportion of windows, such as curtain wall and the outcomes could be directly employed for the other applications requiring the geometry information of façade features, such as building retrofitting and energy simulation. A laser scanning point cloud dataset of the Civil Engineering Building in the University of Cambridge is used for validation, which is an appropriate case with curtain wall and a large number of windows on the façade and the results demonstrate the effectiveness of the proposed framework.

Literature review

The reconstruction of geometric models of building façades from point cloud data has been explored by many researchers. For example, Truong-Hong et al. (2012)introduced an algorithm designed to identify building boundaries and features, employing a method that transforms point cloud data into a robust solid model through the implementation of voxels within an octree representation. This approach was deployed on the façades of three masonry buildings, exhibiting proficiency in detecting all apertures and accurately reconstructing the façade boundaries. Previtali et al. (2014) developed an automated methodology to derive highly detailed 3D vector models of existing building facades from terrestrial laser scanning data. The methodology involves segmenting the point cloud of a building facade into its planar elements and then generating 3D vector models based on the facade break lines.

The openings, such as windows and doors are always used for façade segmentation. Pu and Vosselman (2009) proposed a knowledge-based approach for façade detection, utilising walls, roofs, protrusions, and doors as features for identifying façade elements. The geometric reconstruction was viewed as a process involving polygon fitting, along with the generation of knowledge-based assumptions to address occluded parts in the proposed approach. Zolanvari et al. (2018) introduced the improved slicing method for detecting opening boundaries, including those on roofs, such as chimneys, as well as determining a building's overall outer boundaries through a local density analysis technique.

The plane fitting and clustering methods, as well as the use of a projection method to simplify a 3D scenario into a series of 2D ones, are suitable for relatively simple structures. However, when dealing with a diverse range of existing building types, such as complex architectural buildings or multi-planar building façades, these approaches tend to lack robustness in façade segmentation. For example, Hamid-Lakzaeian (2020) developed a multi-planar algorithm to detect the principal façade across the entirety of multi-planar masonry building facades. The algorithm further identifies recessed and protruded sections within each portion of the principal façade.

To identify the actual geometries for non-rectilinear openings and extract complicated facade boundaries, Iman Zolanvari and Laefer (2016) introduced the slicing method for extracting overall façade and window boundary points, enabling the reconstruction of a façade into a geometry compatible for computational modelling. It detected free-form openings and overall boundaries in building façades, even when faced with complexities and out-of-plane protrusions. Hamid-Lakzaeian (2019) proposed the Gridded-RANSAC approach to segment point cloud façade, which is particularly applicable to highly ornamental masonry buildings with non-rectilinear openings. Xia and Wang (2019) proposed a facade separation method capable of dividing connected facades into distinct building instances. This method can effectively detect complex windows, including bay windows, and identify a subset of individual façades based on dividing lines.

In addition to making reconstructions using TLS data, some studies have proposed reconstructing building façades from images. Zhao et al. (2021) outlined a BIM-based image management framework for reconstructing as-is building 3D models from fragmented images. This is achieved by registering and aligning UAV images onto BIM, matching building façade components in the BIM model with those in the UAV images. This approach primarily focuses on flat building façades with windows and doors, rather than emphasizing non-flat facades or buildings without façade components. Murtiyoso et al. (2021) proposed an approach to semantically segment building façades using deep learning, deploying the DeepLabv3+ network and training it on a database of labelled building façade images. The proposed approach facilitates the transition between 2D orthoimages and 3D point clouds. Bacharidis et al. (2020) reconstructed building façades in urban environments by establishing and leveraging a relationship between stereoscopic images and tacheometry data. This approach involves combining image and georeferenced data to extract meaningful attributes for the structural elements of the façade, including positional, appearance, and depth-related features.

Some studies have explored combinations of various techniques or features extracted from point cloud data for façade detection. By leveraging the advantages of 3D point cloud and 2D optical images, Wang et al. (2018) described a building facade feature extraction method for extracting building facade features, mainly structural information, from 3D point cloud. The proposed method involves image feature extraction, exploring the mapping method between image features and 3D point cloud data, and optimising the initial 3D point cloud facade features while considering structural information. Macher et al. (2021) investigated the use of radiometric information, specifically colour and intensity, for segmenting windows from façade point clouds. Jarząbek-Rychard et al. (2020) proposed a supervised approach for extracting façade openings, specifically windows and doors, from photogrammetric 3D point clouds, utilising both RGB and thermal infrared information.

In summary, previous studies discussed various approaches for building façade reconstruction, including deep learning for semantic segmentation in point clouds, slicing and clustering methods, supervised extraction of façade openings utilising RGB and thermal infrared data, and extracting façade features by combining 3D point cloud data with 2D images. However, these studies are still limited to building façades with rectilinear and repetitive openings or façades with multi-planar surfaces and openings in complex shapes, which are mainly urban traditional buildings. These building facades are typically composed of concrete or brick blocks with low reflectance materials. There is a lack of studies focused on building façades with a big proportion of windows, such as curtain wall, and no studies have been conducted to further extract the geometry information of the recognised windows in an automatic manner.

Research methodology

To enrich the knowledge of building façade reconstruction from high-reflectance materials, this research proposed a digital twin-enabled framework for automatically generating the geometric information for building façades. The developed modelling methodology is applicable to unstructured point clouds containing tens of millions of points. Each point is parameterised by its spatial coordinates and may also include related attributes, such as intensity or colour, but it does not share any topological relationships with nearby points. In the proposed approach, the scan registration process is conducted in the CloudCompare software, and the rest steps are implemented in Python to process the point cloud data.

The input point cloud can be generated by a single or multiple laser scan. After scan registration, scans are merged into a specific data structure. The overall procedure is illustrated in Figure 1. Once all scans are collected and registered in the CloudCompare software, it is essential to determine the windows from the façade. As mentioned earlier, the glass window is high-reflective material, therefore it is difficult to be fully scanned by laser scanners. In this case, the points reflected by the windows could be sparse and random. To detect the windows from the point cloud, it is essential to remove the points of glass as these points will influence the object detection of windows and need to be regarded as noises. A filter process is developed to identify the points reflected by windows. Usually, the intensity feature can be applied for the detection of this glass window on the façade (Macher et al., 2021). The filtering

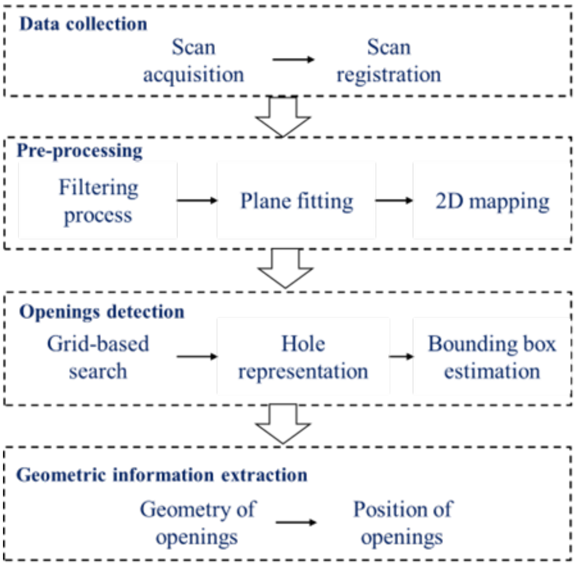

Figure 1: Pipeline of the facade reconstruction process

process is developed based on the intensity feature of the point cloud and implemented in Python.

After the removal of the glass window points, the next critical step is to detect the points belonging to the windows. The main elements constituting the façade are firstly identified by standard random sample consensus (RANSAC) algorithm. The RANSAC algorithm is an iterative method to estimate parameters of a mathematical model from point cloud data (Chum et al., 2003; Wang et al., 2021). The main plane of the façade can be computed based on RANSAC and this plane will represent the façade surface. At this stage, the point cloud data is still in 3D level. To efficiently detect the openings, including windows and doors, from the 3D point cloud data, this study adopts the mapping approach to project the 3D point cloud data onto the façade surface, which is a 2D point cloud data to identify the openings.

To detect the openings from 2D point cloud data, grid-based search for openings is performed and implemented in Python. The size of the grid needs to be determined. If the size is too big, details of the openings' boundary will be lost in the discretization and the accuracy of the dimensions could be decreased. If the grid size is too small, the grid loses its advantages over the point cloud. In general, the size will be determined by the resolution of the point cloud data and the application's requirements, which is set as 3 cm in this research.

A grid representation of point clouds for detecting hole boundaries is commonly used in previous research (Nguyen et al., 2012). The flowchart of the grid-based search approach for the openings detection is shown in Figure 2. A 3 cm $\times$ 3 cm grid is applied on the 2D point cloud to cover the whole data. Some areas may not be covered by points as they are located in the openings such as windows, therefore, the point cloud may include some holes which are regions with no points. Then, each grid is checked that

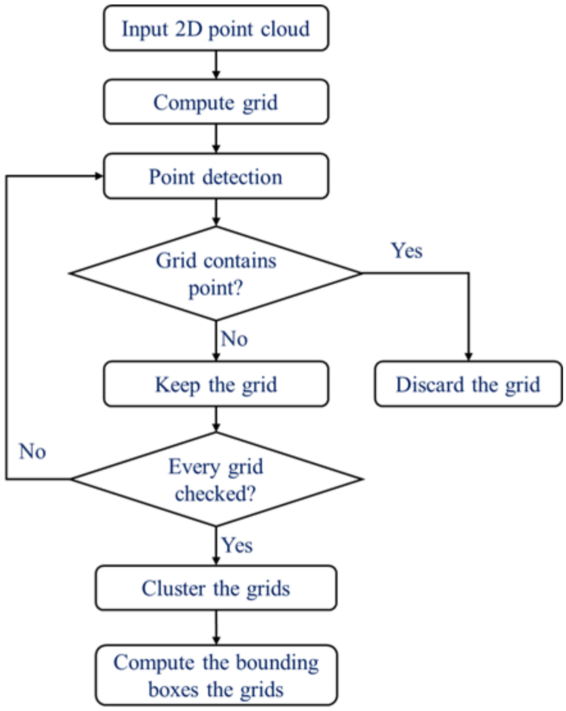

Figure 2: Flowchart of openings detection process

whether it contains point or not. If a grid has no point inside, the grid will be kept as the openings. After all grids have been checked, the openings from the façade will be detected.

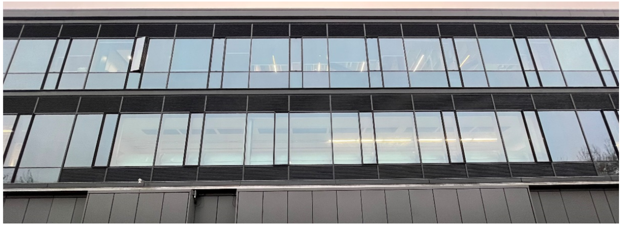
Finally, the remaining grids are clustered, and each cluster represents one opening on the façade. A convex oriented bounding box (OBB) is computed and considered as the boundary of each opening. In this case, a primitive geometry of rectangles is fitted to the opening. The height and length of the opening are be calculated by their minimum and maximum x and y coordinates. Therefore, the geometry information of openings can be extracted from point cloud data and this step is implemented in Python.

The proposed approach is capable of detecting the facades and the details, such as windows. Moreover, this research is also suitable for building façades with high reflectance materials. A real building with window façades is employed in this study to demonstrate the effectiveness of the proposed method.

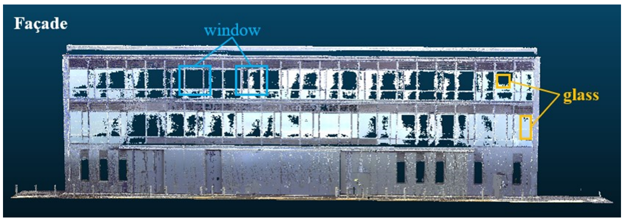
Results and discussion

Case background

The terrestrial laser scanner Faro was adopted for data acquisition in this study. After the scan registration, the building façade of university building was collected. To test the proposed framework, this research cropped one piece of façade for the experiments. The picture of the building in Figure 3 demonstrates the façade is composed of glass windows. From the point cloud, it indicates that the glass windows were scanned, but few points lie on the glass because of the high reflection.



(a) Picture of the building façade



(b) Point cloud of the building facade

Figure 3: Building façade of case study

Experiment results

The filter process is adopted to remove these noise points. As proposed in methodology section, the filtering of points of glasses are based on the intensity feature of the point cloud. The scalar field image of the point cloud intensity is shown in Figure 4. The points with intensity values out of the range will be displayed in grey. In Figure 4, the range of the intensity values is from 158 to 65,535. It is obvious that the intensity values of the glass in the windows are below 158, which can be used as the threshold for filtering the noises in the windows.

The point cloud after the filtering process is given in Figure 5. It demonstrates that the filtering process has effectively remove the points of glasses in the point cloud. Based on the comparison of the point clouds of the original one and the one after filtering process, most of the points, which are appeared grey in Figure 4 have been removed. The Figure 5 shows a cleaner point cloud without the influence of the high-reflection materials on the façade. The results proved that the intensity feature of the point cloud could be capable of removing the noises caused by high-reflection materials of building's façade, such as glasses.

As proposed in the Figure 1, the cleaned point cloud was fitted with an optimal plane based on RANSAC algorithm. The plane that represents the façade surface has been identified. Therefore, the points on the façade were projected on the plane. Therefore, a 2D point cloud was generated. This 2D plane was used to detect the edge of the window frames on the façade surface. As proposed in the Figure 2, the 2D point cloud will be processed with the openings detection process to find the windows from the point cloud.

After applying the openings detection process, the openings were detected from the 2D point cloud, as shown in the Figure 6. It is obvious that all windows can be successfully detected. As given in the Figure 6, the openings are represented as clusters in different colours. By comparison with the original point cloud data in Figure 3, most of the glass windows were detected despite the high-reflection issue caused by the façade. Among them, for the second floor, all the windows were successfully identified and separated. For the first floor, on the left side of the façade, all the windows were also segmented and separated. In regard of the right side of the windows, the lower smaller windows were not successfully separated, and this is because the original point cloud was not scanned completely, and the window frames of some smaller windows were not scanned. Thus, it is challenging to separate these small windows with the detection process. This situation is caused by the quality of the scanned data.

After the detection process, the final step is to extract the geometry information of these openings as given in Figure 2. The bounding boxing method was adopted to estimate the boundaries of these openings, so that each cluster can be represented as a rectangular box. The result of the bounding box estimation is given in Figure 7(a). After that, the geometry information of each bounding box can be used to estimate the geometry information of the windows, as seen in Figure 7(b). The coordinates of the four vertices of the bounding box were computed, thus, the location, width and length of each window were obtained. In summary, with the proposed framework, the geometry information of the openings in the façade can be extracted automatically.

Discussions

According to experiments using real case point cloud data, the effectiveness of the proposed framework was validated above. In contrast to prior studies centred on general facades, our research pioneers a novel method for detecting facades with high-reflectance materials. The filtering process successfully removed points related to glass by utilising the intensity feature, allowing for the identification of openings. The results demonstrated the successful detection of glass windows from the point cloud, with approximately 94% of openings detected correctly.

The grid size used in this case is 3 cm for the openings detection, as defined in the method section. However, based on the alignment between window clusters and the point cloud before the detection process, some variations were observed among window boundaries and the facade. This might reduce the accuracy of the extraction of the geometry information. Therefore, it is suggested that the grid size used might be too large for accurate detection. For more precise geometry information generation, the grid size needs to be set smaller, or further experiments need to be conducted to determine the optimal grid size.

According to the Figure 7(b), it indicated that some small windows were merged as one window. However, it is because that they were not completed separated. A filtering algorithm could be developed to filter these windows

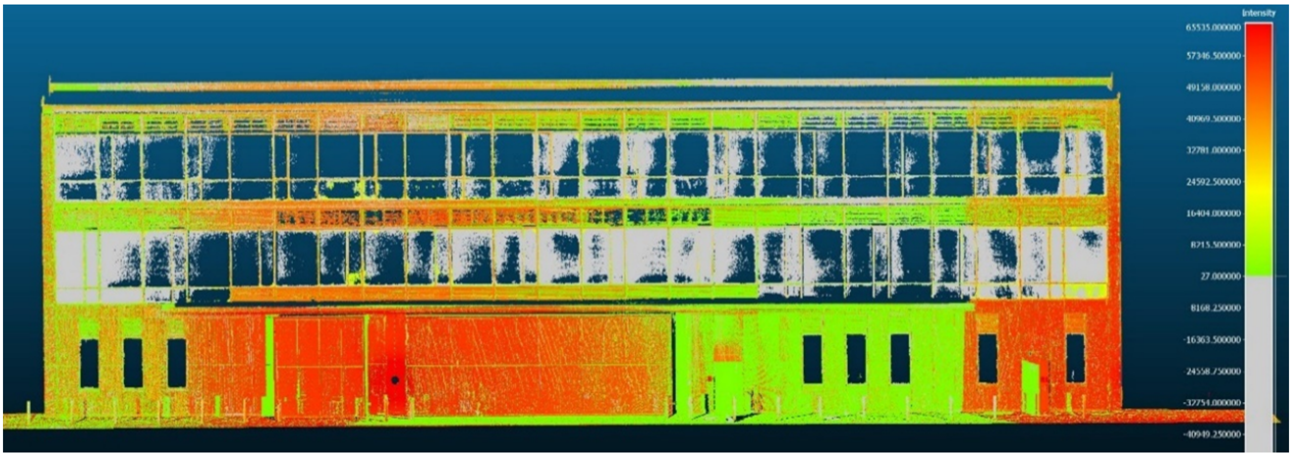


Figure 4: Scalar field of point cloud intensity

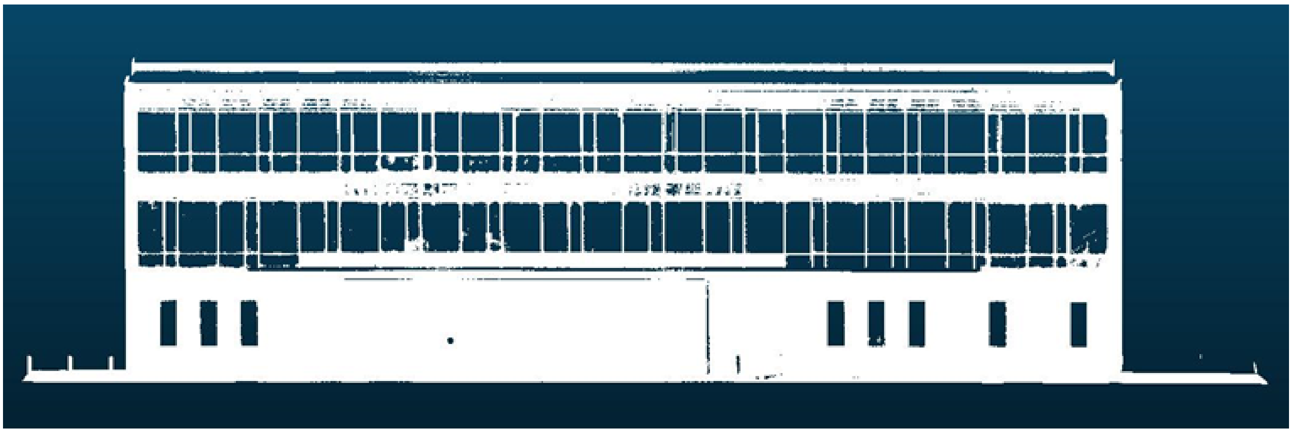

Figure 5: Point cloud after noise filtering process

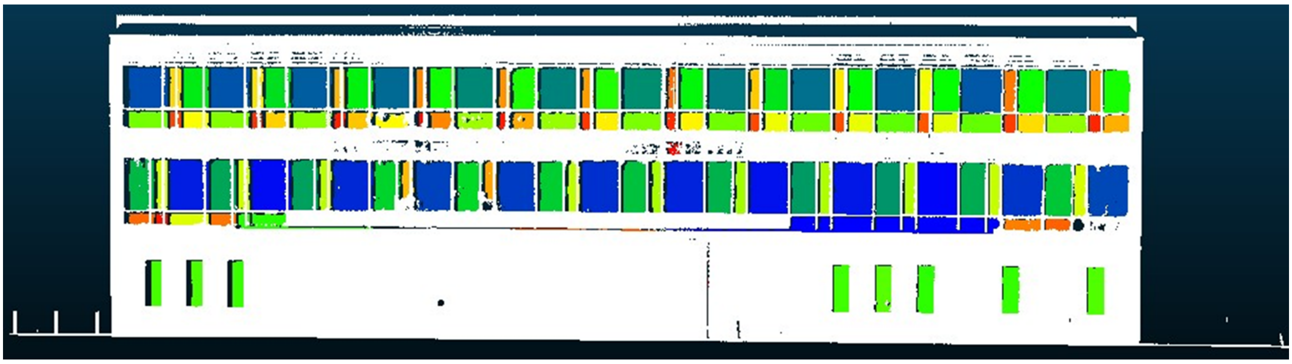

Figure 6: Point cloud after openings detection process

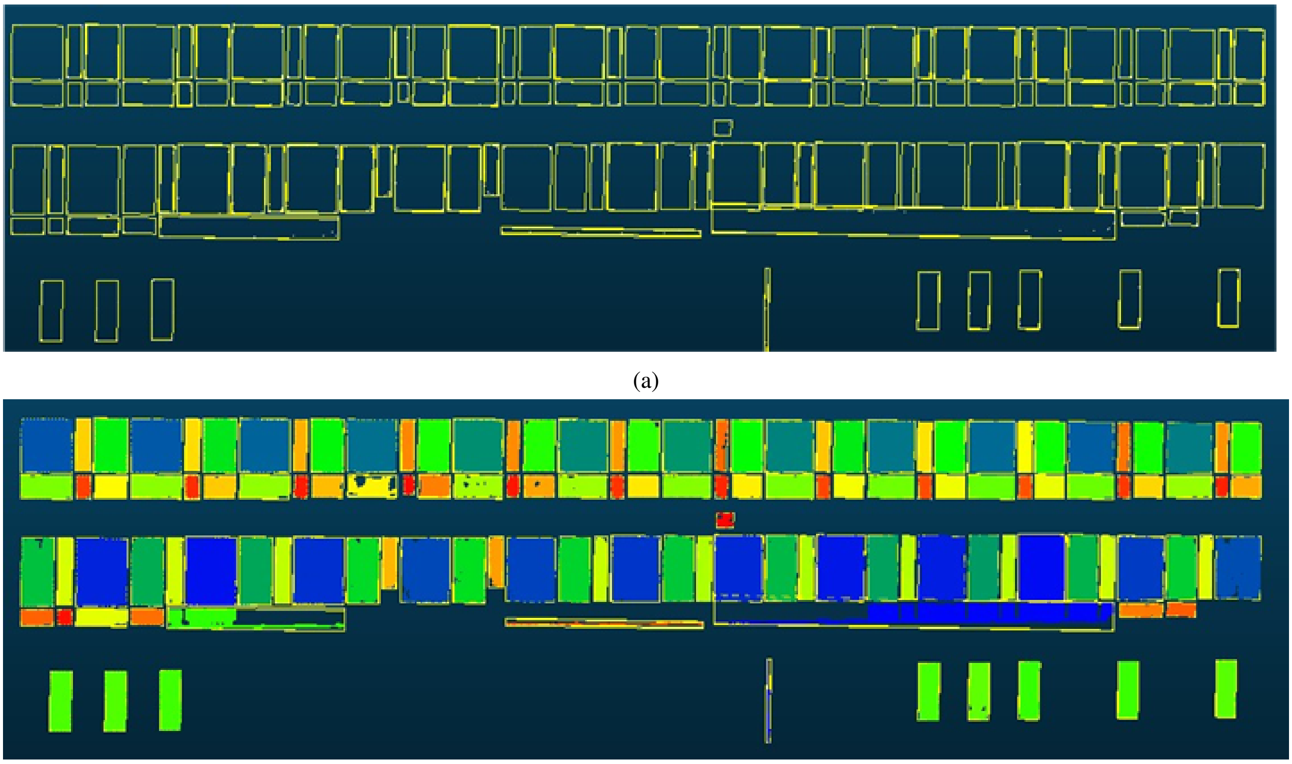
which need to be recognised as errors. Based on prior knowledge of building, some limits could be set for the width and length of the windows that can be used as criteria for filtering the errors, therefore improve the accuracy of the detection.

Regarding geometry information, this research assumes that windows are regular rectangular shapes, which aligns with actual practices in real cases. The extracted geometry information can be directly applied to future building energy simulations. This study opens the opportunity to automate the process from the point cloud to energy simulation, and further investigations could be conducted for this purpose.

Conclusions

The main contribution of this study is the development of the approach to extract building features of a facade with a big proportion of windows, such as curtain wall. The framework includes automated detection of the facades and glass windows from the building's point cloud. Specifically, the geometric information of the recognised windows could be automatically extracted from the point clouds. The proposed framework is validated in an existing building, and the results demonstrate its effectiveness. The



(a)

(b)

Figure 7: Bounding box estimation of the openings: (a) bounding boxes (b) bounding boxes and windows

outcomes could be directly employed for the other applications requiring the geometry information of façade features, such as building retrofitting and energy simulation.

Additionally, this research has the potential to enrich a geometric digital twin of the façade with details. This automatic approach enhances the accuracy and efficiency of the point cloud process. The limitation of this research is that the proposed approach was validated only on one case study. More types of façades could be also included to validate the effectiveness of the proposed approach. Future work in this area includes the extension of this technique to capture an entire building (exterior and interior objects) and to generate more complicated structures and building elements such as roofs, free-form surfaces, internal objects (e.g. ceiling, internal walls), shading elements, façades of non-terraced buildings, and skyscrapers.

Abstract

This paper presents the outcomes of an innovative safety project integrating Health and Safety standards, Building Information Modelling (BIM) and wearable sensors to address safety on construction sites. The paper presents a framework and a prototype that integrates 4D BIM and a real-time tracking sensing system. The 4D BIM virtually identifies and collects the data of hazard zones which is synchronized with the tracking-based sensing system and is used to monitor the access to and interactions with risky zones on construction sites. Real-time alerts are automatically triggered in case of unauthorised trespassing to proactively prevent accidents. The collected monitoring data are then visualised within the 4D BIM model, enabling stakeholders to identify trends and evaluate the effectiveness of safety measures. The integrated system was validated in a construction site and showcased a shift to proactive safety measures, improving hazard identification and control.

Introduction

Construction sites are widely considered one of the most hazardous work environments due to their constantly evolving and unpredictable nature, encompassing high-risk activities, and the frequent interaction between workers and machinery (Jin et al., 2020; Kulinan et al., 2024) The latest report from the Health and Safety Executive (HSE, 2023) documented a total of 135 fatal injuries in work-related accidents in Great Britain in the year 2022/23, 45 of which were within the construction sector, making it by far the leading sector in fatal accidents. The report also highlighted a total of 53,000 non-fatal injuries within the construction sector for the same year. One of the major causes of injuries and fatal accidents in construction sites is "unauthorised incursion" (Jin et al., 2020; Shuang et al., 2019). Unauthorised incursion refers to the entry or presence of an onsite person in an identified hazard zone without a permit, reflecting his role or competence relative to that zone. According to HSE, many contractors in the UK address this issue by employing traditional engineering controls from the hierarchy of controls, Figure 1, by providing workers with Personal Protective Equipment (PPE) and installing physical barriers (e.g., safety bollards, tapes, barricades, toe boards, signs, cones, etc.) to protect and isolate workers from hazards. Although traditional barriers can mitigate some of the risks on site, they are associated with several limitations. These include labourious and time-consuming installation, vulnerability to trespassing or destruction, and a lack of proactive and early warning mechanisms (Ding et al., 2022; Kulinan et al., 2024). Hence, over the last two decades, many researchers and industry practitioners have sought different ways to address such limitations and improve safety measures by proposing various digital technologies which is referred to in this study as an innovative measure, i.e., digital control, to the Hierarchy of Controls, (see Figure 1). These digital technologies include Building Information Modelling (BIM), IoT devices, extended reality, wearable and embedded sensors, and robotics for identifying and controlling onsite hazards.

These emerging technologies are integrated into construction safety management owing to their capabilities for automated hazard identification, real-time monitoring, proactive warnings, and data-driven decision-making. Although technologies in general contributed significantly to enhancing safety measures in construction sites, it remains difficult to meet high safety standards especially when these technologies are solely employed or not incorporated with safety standards and protocols (Jin et al., 2020; Wang et al., 2022). Therefore, this paper introduces an integrated safety system designed to overcome previous limitations, aiming to identify and control hazard zones, fostering mutual interaction between the virtual design model and the physical site.

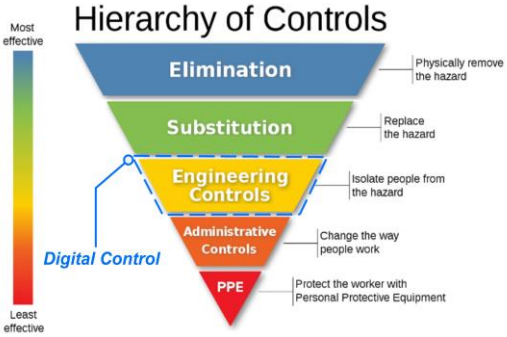

Figure 1. The Hierarchy of Controls Framework; with Digital Control integrated into the Engineering Control layer.

Related Studies

Various digitalization-based safety systems have been developed and introduced to enhance safety measures and prevent incidents in construction sites by identifying, monitoring, and controlling onsite hazards. Table 1 presents a summary of related studies and characterization of their safety systems to better highlight the innovation and contribution of our system. The characterization examines the studies based on several criteria that examine the level of automation, effectiveness, and responsiveness of the presented safety systems. The characterization examines the studies based on the below criteria that inspect the level of automation, effectiveness, and responsiveness of the presented safety systems.

- *Hazard identification mechanism* that investigates the type of technologies used to identify and highlight safety hazards whether during the design in virtual models or during construction on site. It also checks whether the project programme was considered as it is key to include the time dimension and the activities sequence when identifying hazards to be monitored. For instance, when identifying a hazard zone, its associated activities, and their start/end times should be available for the monitoring system to be activated/deactivated based on such data.

  In general hazard identification technologies include BIM, extended reality, and computer vision. BIM has proven to be an effective tool in safety management during the design phase by enabling designers and planners to highlight safety hazards in the design models and propose mitigations. However, BIM independently lacks dynamic data from the construction site that should be streamed in real-time to accurately depict what is currently happening on site (Kulinan et al., 2024). Therefore, BIM by itself is not sufficient for managing safety and requires the integration of IoT and sensing devices to provide timely data during construction.
  Extended Reality (XR) technologies have also been widely adopted in safety management to provide an immersive and interactive environment to identify and visualise onsite risks (Wu et al., 2022). Their adoption has mainly been for providing safety training to construction workers where safety instructions and guidelines are displayed for identified hazards, enabling the worker to manage onsite hazards effectively and interactively.

  Other technologies have also been used to identify onsite hazards including computer vision-based approaches. Many researchers proposed vision-based safety systems that collect and process visual data to recognise onsite risky behaviours of construction workers or equipment. Despite their automated approach to identifying potential hazards, computer vision techniques are limited to certain safety scenarios and types of objects that were trained to detect and recognise (Kulinan et al., 2024). Furthermore, these systems require a clear and uninterrupted visual data stream which in many construction sites is not easy to ensure due to their dynamic nature with various moving parts.
- *Hazard monitoring mechanism*, looking into the types of technologies used to collect and process data from the construction site and whether this mechanism is fully automated or not. There is a wide array of different sensing and IoT devices adopted in the literature depending on the type of data that needs to be collected. For example, in most safety applications, location data of onsite personnel or equipment is mainly needed, and it is generally collected using position sensors (e.g., GPS). In other applications where the motion data of equipment is required, motion sensors (e.g., IMU) are mainly used. In some studies, visual sensors (e.g., CCTV cameras) are favoured to acquire images or video streams that can be used to monitor hazard zones.
- *Hazard controlling mechanism*, ensuring the safety system leverages real-time and automated controlling mechanism that alerts people from potential hazards and proactively prevents injuries or accidents. For instance, when an unauthorized incursion occurs, it is expected for the system to trigger a fully automated warning in real time to alert the unauthorized person as well as HSE managers. This criterion also investigates whether a system employs visualisations that report and present monitoring data and analysed metrics (e.g., zone interactions metrics) in a timely manner. It also examines whether a learning feedback loop is integrated into the safety system that ensures a continuous learning loop based on the monitoring information from previous reports to enhance the safety measures of future onsite hazards.
- *Integration of Design and construction measures* which checks whether a given study integrated the safety measures during the design phase with those applied during the construction phase and if there is a feedback loop from the construction to the design that can enhance the safety planning of future sites.

As illustrated in Table 1, there is a gap in integrating all these elements into a unified system able to identify, monitor, and control on-site hazards in an automated and proactive manner while ensuring a learning/improving feedback loop between the design and construction.

Research Methodology

This research project was conducted as part of the Discovering Safety initiatives delivered by the Health and Safety Executive (HSE) in the UK. The main aim was to integrate current Health and Safety (H&S) standards, BIM technology, and advanced wearable sensing systems for enhancing safety measures during both the design and construction phases while maintaining a learning/improvement feedback loop between the two.

To achieve this aim, a conceptualized integrated safety framework was developed that incorporates safety measures during the design and construction following the "plan, do, check, and act (PDCA)" followed by the HSE and according to H&S standards. This system was developed with continuous feeding input from key industrial stakeholders including project owners, designers, contractors, HSE representatives, and technology suppliers. The developed framework also presents the integration workflow between the two technologies (i.e., BIM and wearable sensors) that will be employed to identify and manage safety hazards during both phases. In this project, the SafetiBase system provided by 3D Repo was used to identify and capture hazards within the 4D BIM model while the sensing system was used to monitor and control the identified hazards. The developed framework was later implemented in a real construction site using both SafetiBase and Plinx platforms to validate its level of effectiveness and responsiveness to prevent onsite incidents and enhance safety measures.

Construction Safety Integrated Framework

Figure 2 presents the construction safety framework, integrating the BIM technology and the sensing system for managing safety during the design and construction phases. In the design phase, 4D BIM models play a key role in hazard identification within the construction sequence following the PAS 1192-6 standard, as illustrated in Figure 3a. Pre-approved treatment strategies following H&S standards and contractors' best practices are then placed to address those hazards. Where possible, identified hazards should be eliminated or substituted by changes to the building sequence following the hierarchy of controls (recall Figure 1). There are, however, lots of instances where this is not practical and engineering controls must be employed to ensure the safety of the working area during the construction phase.

For each identified hazard, a zone is marked virtually within the BIM model encompassing that hazard (Figure 3b). For each identified hazard, detailed information, including XYZ coordinates, project reference point, and the start and end times of associated activities, is gathered by the Plinx broker through 3D Repo's API. These XYZ coordinates are then converted to WGS84 Lat/Lon by the broker for compatibility within the Plinx system. Plinx effectively activates and deactivates the designated zones at the specified times. The Plinx platform hosts metadata from the risk treatment ticket, involving zone type, purpose, and additional information available in the treatment notes.

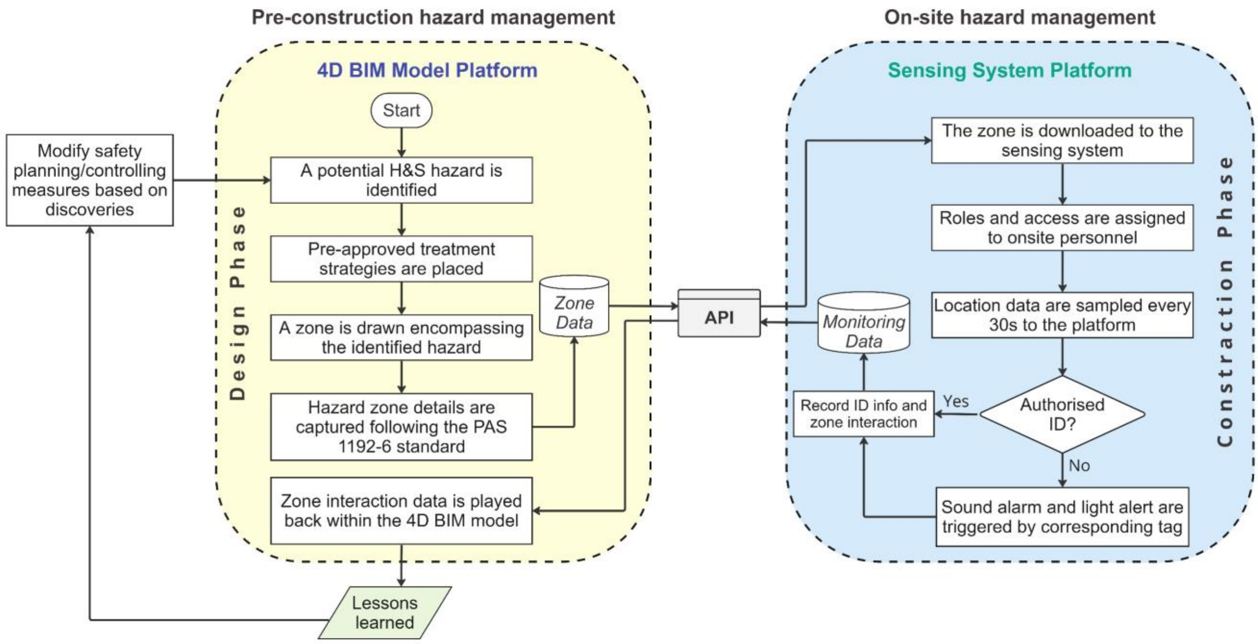

Figure 2. The proposed integrated safety system as a bi-platform management system

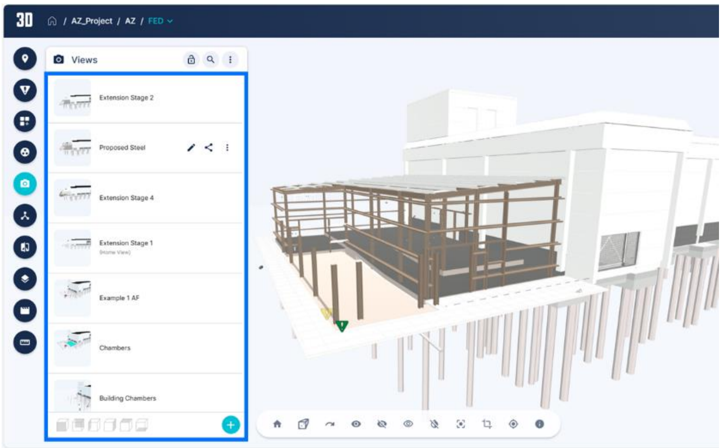
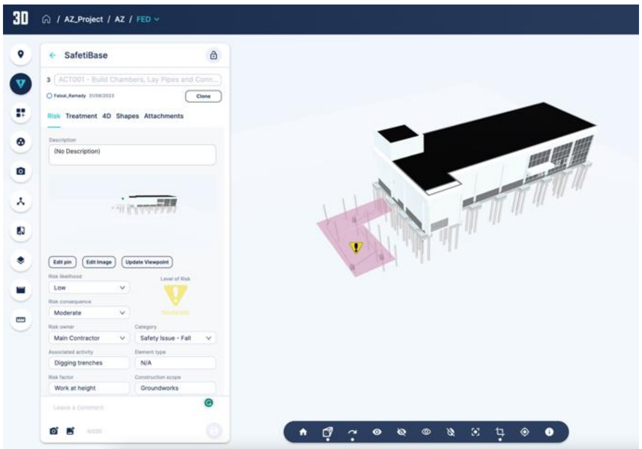


(a)



(b)

Figure 3. Identifying H&S risks virtually in a 4D BIM model using 3D Repo platform: (a) identified hazard activities within the construction sequence, (b) marking up a hazard zone associated with a drainage activity as an example.

Upon receiving zone data, Plinx establishes a connection with its corresponding physical wearable sensors. Before each construction shift, access permits are assigned to onsite personnel based on their roles and competencies, specifying permissions for entry and operation within the designated zone intended to be monitored. Unauthorised access triggers real-time alerts through the automatically activated sensors. The Plinx platform offers real-time visualisation of all monitoring data and zone interactions.

At the end of each shift, zone interaction data, both authorised and unauthorised entries, is promptly transmitted to 3D Repo via API. This includes location data recorded every 30 seconds, accessible through an API call typically conducted at the end of each working day. Plinx ensures the conversion of this data to XYZ coordinates before export. Within the 3D Repo environment, the movement and interactions within zones can be played back onto the BIM model, providing a contextual reference to the initially created zones. Doing so enables reflecting on the effectiveness of the current safety strategies and enhancing the safety planning and management of future hazard zones. This iterative process not only reinforces the practical implementation of integrated systems but also supports the overall efficacy of the H&S risk management framework.

Case Study

To validate and measure the effectiveness and responsiveness of the developed integrated safety framework, an on-site case study was implemented with the main intention of acquiring authentic, real-world data from a dynamic construction site. The on-site trial took place at AstraZeneca's quality assurance building project.

Hazard Zone Setup: AstraZeneca's 4D BIM model was imported into the SafetiBase platform for hazards to be identified and captured. Initially, four construction activities with potential risks were identified — footings excavation, drainage chamber installation, steel erection, and utility connection into the main road. However, given the compact site and the diverse expertise of the chosen subcontractors, establishing safety zones for all these activities based on roles and competencies posed a significant challenge. Consequently, only the steel erection task, which was executed by a specialised team, was selected to be monitored onsite (Figure 4). A safety zone was established around its locations with its hazard details captured in the BIM model following the PAS 1192-6 standard. The zone and its data were then extracted from SafetiBase by the API and sent to the Plinx platform to be monitored on-site during construction.

On the construction site, the WGS84 coordinates of the zone are precisely mapped using a survey rover, (Figure 5a). The survey rover outputs a GEOJSON file which is then uploaded directly to the Plinx platform to validate its alignment with the safety zone plotted in SafetiBase.

Figure 4. The safety zone selected around the steel erecting work to be monitored and controlled.

(a) **(b)** **(c)** **(d)**

Figure 5. The sensing system: (a) a GNSS Rover, (b) RFID card, (c) charging and allocation station, (d) wearable sensor connected to a safety helmet.

Sensing System Setup: The sensing system used to monitor the hazard zone was supplied by Plinx. The wearable sensors were connected to JSP construction helmets as illustrated in Figure 5d. Plinx RFID cards were used to assign operative roles and competencies of onsite personnel against their card IDs', see Figure 5b. Site operatives then scan these RFID cards to receive a sensor with personalised zone access based on their assigned roles relative to the zone.

Safety Zone Monitoring: Following the sensing system set-up, the safety zone around the steel erection work was monitored for one week. The wearable sensors and cards were assigned at the beginning of the working shifts. The wearable sensors transmitted the location data of onsite personnel every 30 seconds. These data points were visually represented on the platform as green dots, as illustrated in Figure 6. The monitoring system was intricately designed to generate alerts in the event of unauthorised individuals entering the designated zone. To assess the system's responsiveness and reaction time, deliberate unauthorised interactions were induced within specific areas of the monitored zone. Upon the entry of unauthorised individuals, their sensors emitted audible beeps and vibrations. The locations of these breaches were then visually depicted as dark blue dots (Figure 6).

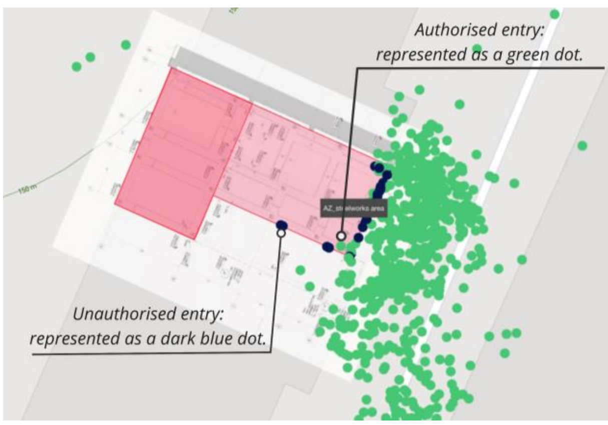


Figure 6. Zone interaction data for a week-period monitoring

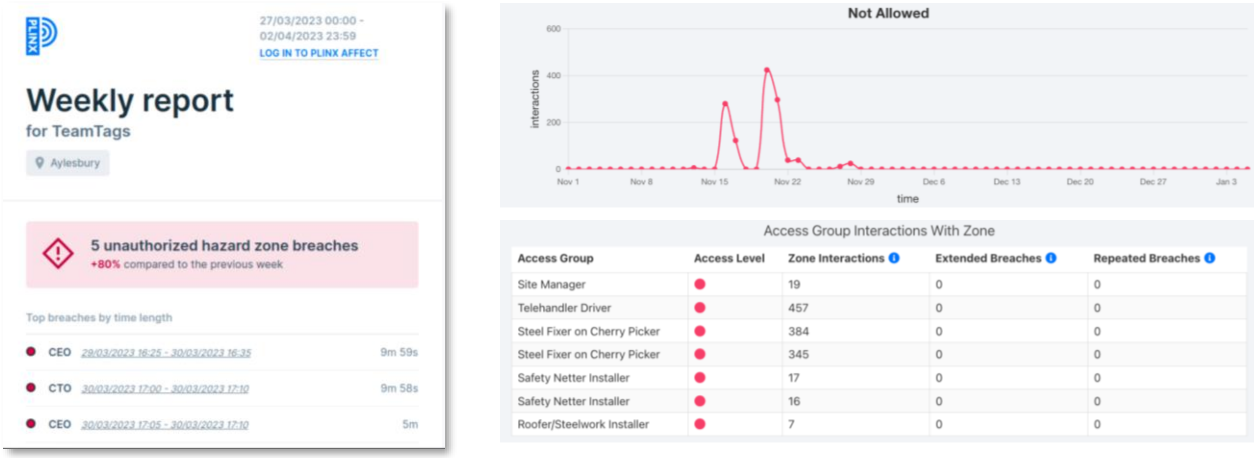
All zone interaction data are recorded and presented in a comprehensive weekly report, see Figure 7. This report includes details such as the number of authorised/unauthorised entries and associated information, including personnel ID and role, date, and time of entry, as well as the duration of their presence within the zone. The gathered monitoring data are used to enhance week-on-week management strategies of safety zones by playing it within the 4D BIM model, as illustrated in Figure 8. More significantly, it plays a crucial role in providing insightful feedback to planners and designers, offering valuable insights into the efficiency of implemented preventive measures. This feedback loop ensures an ongoing enhancement of safety protocols, fostering a dynamic and responsive approach to maintaining and improving overall safety standards.

Results and Discussion

Trial Impact: This work has demonstrated the successful implementation of the developed safety framework integrating H&S standards with digital technologies for identifying and managing hazards on construction sites. The integration of digital technologies has significantly enhanced construction safety through proactive hazard identification and management. Unlike traditional reactive approaches, the digital control system, equipped with automated sensing and monitoring, predicts and prevents potential hazards in real-time. This ensures not only the effectiveness of safety measures but also responsiveness to dynamic site conditions. The system's proactive alerting further strengthens safety by triggering immediate responses to unauthorised individuals breaching safety zones, reducing the risk of accidents. The monitoring system has a detection accuracy within a 50 cm radius, significantly enhancing safety by triggering a warning when a worker approaches the zone at a proximity of just 50 cm at a walking speed of 4 mph. This level of precision surpasses the accuracy of systems documented in previous studies. For example, the system presented by (Jin et al., 2020) gets triggered only when a worker is within a 200 cm distance. Additionally, our system demonstrates real-time responsiveness, with an estimated average reaction time of just 0.3 seconds.



(a) **(b)**

Figure 7. Recorded unauthorised incursions to the zone: (a) an example of a weekly report summary, and (b) data visualisations of the steel work zone interactions over the monitoring period.

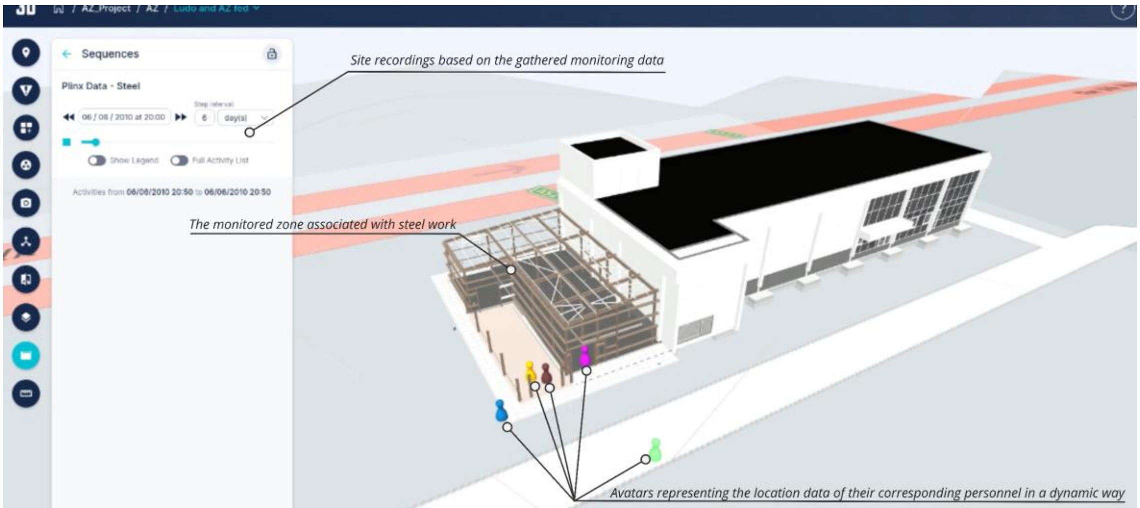


Figure 8. A screenshot from a video displaying the location data gathered during the zone monitoring within the 4D BIM model.

Moreover, the developed system extends data visualisation into the 4D BIM model, providing a comprehensive understanding of the construction site layout and potential hazards. This allows stakeholders to analyse safety data over time, identify trends, and make informed decisions for targeted improvements. The feedback loop in the system plays a crucial role in refining safety protocols by providing continuous, data-driven insights. Unlike traditional post-incident analysis, this system fosters a proactive safety culture, emphasizing ongoing refinement and optimization based on timely feedback.

Limitations and Future Recommendations: While this trial has shown promising advancements in safety management by integrating BIM and monitoring-based sensing, it is crucial to recognise the challenges and limitations faced during implementation. These insights are valuable for refining the system and optimizing its performance in larger-scale construction scenarios. One key challenge involved difficulties in obtaining and applying pre-approved treatment strategies for establishing and marking safety zones. This issue is widespread among contractors due to the absence of a standardized zonal control framework specifying attributes of a given zone based on the construction activity associated with it. The current process has a limitation where the shape drawn in SafetiBase is a freeform polygon. While this provides flexibility, it may lead to discrepancies between the digital zone and the physical segregation on site. A preferable solution would involve the system applying standardized rules to the highlighted hazard, assisting designers in comprehending the spatial impact and aiding the site team in deploying physical barriers more effectively.

It is vital to automatically align safety zones with planned activities to prevent sensor alerts from inaccurately triggering and misrepresenting actual locations. The plan involves developing a customised SafetyZone interface within 3D Repo to enable safety managers to authorise and restrict zone access to operatives, machines, or groups seamlessly as part of the system workflow. It is also worth noting that the deployment of sensing technologies, particularly monitoring personnel through wearable sensors and collecting location data, raises privacy and data security concerns. Achieving a careful balance between enhancing safety and respecting individual privacy rights is essential. Implementing robust data security measures is crucial for ethical and legal considerations, ensuring responsible use of the collected data and compliance with privacy regulations.

Conclusion

This work presented a construction safety framework that integrates H&S standards with digital technologies to enhance safety planning and management in construction sites. This innovative approach represents a shift from reactive to proactive safety measures. Utilizing BIM for virtual hazard identification and real-time monitoring through sensing technology, the integrated system predicts and prevents potential hazards, reducing the likelihood of accidents. The developed system also enables visualising monitoring data within the 4D BIM model, offering stakeholders a comprehensive understanding of the site and supporting continuous improvement through a dynamic feedback loop between the design and construction phases.

Acknowledgements

This safety project was built upon a five-way partnership involving: Discovering Safety—a five-year programme being delivered by HSE and funded by the Lloyd's Register Foundation, AstraZeneca's construction team, on-site support from Dalkia, and the two technology suppliers— Asite 3D Repo and Plinx.

Abstract

Increased accessibility to additive manufacturing technology facilitates democratization of manufacturing, bringing it to habitable environments. The operation of additive manufacturing can be hazardous to human health mid-long term. Virtual sensing extends the capabilities of hardware sensors enabling affordable monitoring to ensure safe operation in democratized manufacturing environments. However, the development process has not yet been standardized for informally trained personnel to facilitate the adoption of virtual sensors. This paper presents a case study analysis to propose a standardized process for the data collection and development of virtual sensors for indoor air quality monitoring in democratized manufacturing environments.

Introduction

Democratization of manufacturing is driven by personal digital fabrication (Mota, 2011; Anderson, 2012; Gershenfeld, 2012), which enables informally-trained consumers to meet their production and customization needs (Browder et al., 2019). Increased access to fabrication technology like Additive Manufacturing (AM) or 3D printing (3DP) brings digital fabrication to ad-hoc manufacturing spaces at home, university, and start-ups that are not designed to manage the harmful emissions for human health (Ford & Despeisse, 2016). The widely adopted Material Extrusion (ME) 3DP technology typically utilizes thermoplastic or thermoset polymers as feedstock materials (Ligon et al., 2017), releasing Volatile Organic Compounds (VOC) and Particulate Matter (PM) during their operation. If inhaled, PM (PM2.5 or smaller is smaller than 2 µm) can reach the alveolar region of the lungs and be transported by the bloodstream to other organs (Pilou et al., 2015). (Afshar-Mohajer et al., 2015; Azimi et al., 2017) proved that VOC and PM in indoor environments for AM can greatly exceed the safety thresholds (World Health Organization, 2016).

Indoor environments where AM technology is deployed must be controlled to limit these health hazards since informally trained personnel are neither aware of the health hazards (Berger et al., 2023; Schieweck et al., 2018). Many authors have addressed the characterization of emissions in terms of VOCs and PM from 3D printing processes under controlled laboratory environments (Afshar-Mohajer et al., 2015; Bravi et al., 2019; Kim et al., 2015; Mendes et al., 2017; Pernetti et al., 2023). These works of characterization of pollutants mostly focus on single sampling of emissions using high-end equipment. Nevertheless, these solutions are not transferable to the built environment (e.g., in offices, classrooms, and makerspaces) due to the reduced number and cost of sampling equipment. In contrast, low-cost sensors are accessible and affordable solutions to monitor the emissions in additive manufacturing and larger environments. The caveat of using low-cost sensors is the lack of accuracy of the available technology to detect emissions. Plus, makers are not willing to add the extra cost of sensors due to their lack of awareness. Some authors try to make low-cost monitoring feasible by integrating it with signal processing and analysis (Stefaniak et al., 2021; Vogt et al., 2021; Martínez-Comesaña et al., 2022; Tagliabue et al., 2021). These techniques can be automated via virtual sensors to increase awareness on IAQ for 3D printing users.

Virtual sensors are online instruments of measurement that supplement other monitoring entities (Lin et al., 2007; Montague et al., 1992; Martin et al., 2021). Virtual sensors have been used to estimate NO, NO2, NOx, SO2, O3, CO, Cd, PM2.5, and PM10 concentration and virtually recreate the pollution in the built environment, in entire neighborhoods (Benabbas et al., 2019; Dogeanu et al., 2019) and undergrounds (Loy-Benitez et al., 2020; Loy-Benitez et al., 2022). Applications of virtual sensing to measure indoor air quality (IAQ) in the literature are still limited to controlled environments (Leidinger et al., 2014; Zaidan et al., 2020), but has proven to be a feasible option for monitoring comfort indoors (Kowli et al., 2023). Virtual sensors can also be used to monitor targets that are out of reach (i.e., it is not possible to install a hardware sensor), and to reduce the number of sensors required making the final solution more affordable. Given the limited literature in the context of democratized manufacturing, there is still no standard process to guide the development of virtual sensors for IAQ.

This paper aims to kick-off the design of a standard process for the development of virtual sensors for IAQ monitoring in ad-hoc democratized manufacturing spaces. The process learns from the ad-hoc solutions in the literature and the analysis of a case study that implemented a virtual sensor model in a 3D printing environment.

Context and case study analysis

The key elements of a case study design are (Priya, 2021):

(a) Purpose of study: To create a data collection protocol and a training and deployment process for virtual sensors to monitor IAQ in a democratized manufacturing environment.

(b) Type of case study research: exploratory case study.

(c) Research question: How to develop and utilize virtual sensors for IAQ monitoring?

The context of the case study is a democratized additive manufacturing environment in a commercial office building. Herein, the study focuses on a cabinet hosting four printers Creality CR20-PRO Fused Deposition Modelling (FDM), an ME technique. FDM 3D printing principle consists in building three-dimensional solid objects from their digital models by selectively accumulating liquified thermoplastic material (e.g., PLA, ABS) layer-by-layer (Anon, 2024; ISO/ASTM, 2013) into a bed where the material cools and cements, shaping a geometry. The cabinet is enclosed for the sake of safety in terms of limiting the emissions released into the rest of the shared working environment; yet this space represents a practical democratized manufacturing space in terms of size, purpose, and the level of available resources. The dimensions of the cabinet are 200x90x100 cm (see Figure 1). It is composed of a desk and eight methacrylate panels for two side panels, four access windows, two sliding windows in the back and the ceiling, plus a single extraction point in the center of the ceiling panel. Extraction works at the same speed but can be turned on and off. The goal of monitoring in this space is to raise awareness on health for the users in terms of utilization of the space, and the cabinet, and pollution escaping the cabinet during operation of the 3D printers.

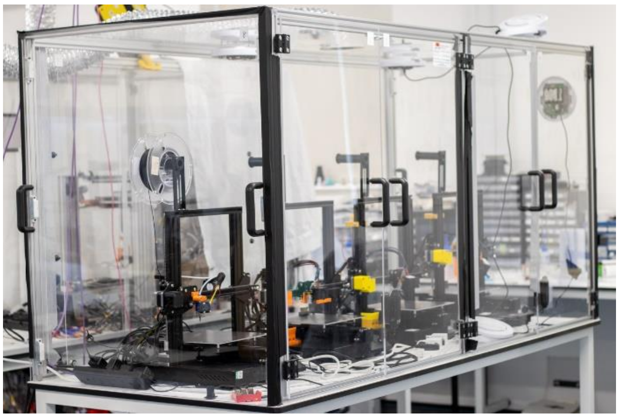

Figure 1. Cabinet hosting four 3D printers for relevant data collection under democratized manufacturing settings.

Virtual sensor data collection, training, and deployment process

This section explains the process for collecting IAQ data and training and deploying virtual sensors in the democratized additive manufacturing environment. This process is addressed to occupants operating democratized additive manufacturing environments and data practitioners interested in monitoring air quality indoors.

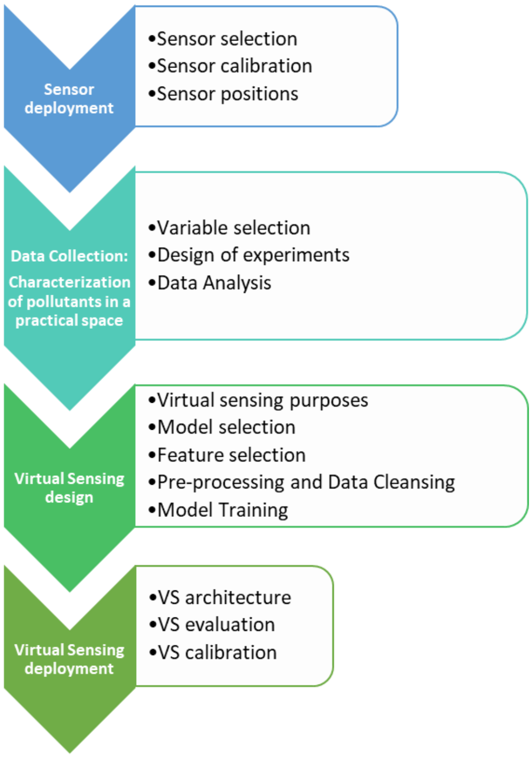

Figure 2. Process for data collection and development of Virtual sensors for IAQ monitoring.

Figure 2 summarizes these steps in the process, which are the result of the analysis of literature on IoT deployments (Bashir et al., 2022; Bibri, 2018), prior knowledge in other areas (Merino et al., 2022), and adaptations from the application of each step to the domain of IAQ.

Low-cost sensor deployment

An effective sensor deployment is launched by appropriate selection of sensors. Sensor selection must be informed by literature in the domain as well as a market review. For instance, in the context of 3DP, (Afshar-Mohajer et al., 2015; Bravi et al., 2019; Kim et al., 2015; Mendes et al., 2017; Pernetti et al., 2023) used chamber setups to characterized the emissions of popular 3DP filament materials like PLA, ABS, HIPS, and PC, resulting in particulate matter (PM) and diverse species of volatile organic compounds (VOCs).

Sensors shall be calibrated before deployment. Although manufacturers claim that sensors have been calibrated in laboratory environments at source, they need to be calibrated in the field since fabrication variance is not avoidable yet in low-cost sensing. The calibration methods for air quality monitoring vary (Chowdhury et al., 2023; Zaidan et al., 2020; Zarrar & Dyo, 2023; Tariq et al., 2020; Zimmerman et al., 2018), but share the notion of comparing against a source of truth. Often these sources of truth are high-quality sampling equipment.

This equipment comes at a high price tag both for purchasing and for single-time calibration from the manufacturer, which may be prohibitive for some makers. Furthermore, concept drift (De Vito et al., 2024) appears when operating conditions change from those encountered during training set recording, the derived calibration accuracy drops. Thus, calibration should be considered over longer-time of monitoring to account for seasonal differences and sensor drifts. Alternatively, some authors targeting scalable calibration have proposed median calibration, which is obtained through using datasets considering the median response of several sensor units to identical field recorded conditions (De Vito et al., 2024).

Finally, the position of the low-cost sensors in the space must be designated for deployment. Sensor positioning in air quality monitoring is informed by the identification of sources of pollution and the expected usage of data. The final positions and configuration of sensors must be logged into a repository for traceability and maintenance of the deployment, since hardware sensors can suffer network drops and reconfigurations, power problems, or even complete failure that prompts replacement. For deployments with limited number of sensors, can make them rotate around the intended positions, then later substituted for their virtual counterparts.

Data Collection: Characterization of pollutants in a practical space

The purpose of the data collection is to characterize how the pollutants are dispersed in a practical democratized additive manufacturing environment.

Variables are selected to enable virtual sensing training and operation. Generally, nearby locations measurements are used to estimate PM and VOC, but some authors have used humidity and temperature to improve the accuracy of CO2 estimations (Tagliabue et al., 2021; Zaidan et al., 2020), CO and CO2 and operational parameters of the 3D printers for estimating PM and VOC (Stefaniak et al., 2021).

Experiments must be contextualized in the process of the indoor environment that is causing the emissions. The goals of data collection and literature can support the design of experiments. In the case of semi-controlled or uncontrolled environments, experiments conducted shall cover data collection of a range of practical situations. Experiments should have the same starting conditions and they are repeated for validation of data collection under the same conditions. Experiments can also be repeated for identification of seasonality.

Data analyzed to test the validity and thoroughness of data collection and to identify potential missing conditions for new experiments. Experiments ought to include at least baseline identification (i.e., how is the signal for each variable when nothing is happening) and the range of practical situations devised during experiment design.

Virtual Sensing design

Virtual sensors are used as a backup for potential failures of low-cost sensors, to completely replace them, and to provide measurements in locations hardware sensors cannot reach (e.g., temperature inside a boiler). In the case study, the virtual sensor was designed as a backup for PM1.0 of the low-cost sensor in the same location and to replace it for use in a different space.

Diverse regression and machine learning models have been used to estimate PM and VOC: in terms of indoor air quality, (Stefaniak et al., 2021) used linear regression to estimate VOC and PM concentration in a large-format yet controlled AM lab. (Dogeanu et al., 2019) trained Neural Network virtual sensors on data from fixed air quality stations located in urban areas to estimate the concentration of PM2.5 and PM10 among other pollutants to virtually recreate the pollution in entire neighborhoods. (Leidinger et al., 2014) implemented a virtual sensor based on linear discriminant analysis (LDA) for selective detection of hazardous VOCs using a gas sensor array. Literature can influence model selection, but it is ultimately the decision of the data practitioner which model to select. Comparison between several models is recommended. It is important to understand that models trained in a given space may not be transferable to other spaces unless the geometry and operations are near to identical (e.g., another cabinet with the same setup). Models in the literature should be implemented within the context of the case study to test the validity and enable comparison under desired conditions.

Along with model selection, comes the features to be used to train the virtual sensors. Data analysis should undercover correlations between variables that can support estimations in the models. Literature can also inform known relationships between variables, but they should be confirmed through data analysis.

In most cases, raw data from hardware sensors needs some form of preparation before they are suitable for model training. Typical methods for data preparation are filtering, synchronization, and transformations (e.g., principal component analysis, logarithmic conversion, or derivatives of the original signal). Outliers due to sensor temporary malfunction and missing data due to power or network losses should be identified and removed, and only relevant controlled data from the experiments should be used for training.

With the advent of Machine Learning open-source frameworks, model training is becoming easier than ever. (Nguyen et al., 2019; Wu et al., 2022) compare popular frameworks in terms of capabilities and training and testing performance. The main goal of training is to obtain acceptable accuracy without incurring into overfitting models. This becomes an iterative process of trial and error, and continuous improvement in most cases. In some cases, this iterative process requires the practitioner to apply different pre-processing methods, selecting different features, or conducting further data analysis.

Virtual Sensing deployment

Having a trained model that can estimate the pollutants in a given position is not enough for using a virtual sensor in a practical case. Virtual sensors for IAQ monitoring need to be understood as standalone systems and behave similarly to low-cost sensors. A system architecture is necessary to deploy virtual sensors in a scalable manner (Merino et al., 2023; Martin et al., 2021; Leidinger et al., 2014; Zaidan et al., 2020).

Any type of virtual sensor needs evaluation (Goodwin, 2000), but more importantly when it comes to IAQ monitoring since they are aimed to monitor pollutants that can affect human health. Virtual sensors need long-term calibration (Koo & Yoon, 2022) since their accuracy can decrease because of various uncertainties in the system operation and virtual sensor model.

Case study application and Discussion

This section describes the application of the data collection, training, and deployment process for virtual sensors. Results of implementation are discussed including the identification of the challenges faced and adaptations made to the process.

Sensor deployment implementation

The literature on air quality in additive manufacturing environments guided the selection of sensors. The materials used in the 3D printers are PLA and ABS, which emit PM and diverse species of VOC (Steinle, 2016). The virtual sensor designed focuses on PM. Low-cost sensors available in the market to monitor these two variables are based on the light-scattering principle for PM. Sensors from two manufacturers are used: M1 can measure PM1.0, PM2.5, and PM10, and M2 can monitor PM1.0, PM2.5, PM10, tVOC, Temperature, Humidity, CO2, and Ozone.

Sensors were calibrated using the median approach. While other authors installed sensors in their final position to collect data for median calibration, sensors were collocated in stacks in the same center of the desk inside of the cabinet and shuffled once during the calibration data collection. This deviation from the literature moved the calibration step before the sensor positioning in the process. Median was calculated across all sensors and selected as a general calibration law. A data pre-processing module was added to the data pipeline to locally adjust the differences between each sensor signal and the median. Additionally, a sensor drift analyzer was set up to identify and correct potential sensor drifts due to aging. Calibration was performed per manufacturer.

The positions of the sensors are determined by the positions of the 3D printers in the cabinet. There are four 3D positions for the 3D printers evenly distributed along the Y axis (200 cm long) in the cabinet, centered at 25 cm, 75 cm, 125cm and 175cm. The purpose of devised virtual sensors is to estimate distribution of pollutants within the cabinet, therefore, the sensors (four M1, and fifteen M2) were evenly distributed in the cabinet.

Data collection implementation

Temperature, Humidity, and PM1.0 from all sensor locations are considered. Temperature and humidity have an impact and Particulate matter sensors, respectively and can help to identify seasonal bias.

The following experiment variables were selected: extraction of the cabinet (i.e., can be on/off, when it is on, it always extracts air at the same speed); windows opened (i.e., whether it is planned to open any window during the experiment, monitored by open closed sensors); printer positions in operation (i.e., takes the form of an array of Booleans, e.g., [1, 1, 0, 0] means that only printers in positions 1 and 2 are printing); material (i.e., type of material used throughout the printing, either PLA or ABS from the same manufacturer and model in all the experiments); and nozzle temperature. The experiments consisted of permutations of the variables. For example, experiment 1 included extraction off, windows closed, and 3D printer in position 1 printing a geometry using ABS for one hour. Before each experiment, the air inside the cabinet is exchanged for at least one hour. Experiments with the same conditions (i.e., variable setups) were repeated at least three times.

The baselines of PM1.0 in all sensor locations were identified over a period of 7 hours under non-printing conditions by repeating the experiment with windows open and closed, extraction on and off. For instance, Figure 3 depicts two baselines identified for PM1.0 in the target location (i.e., the sliding window used to access the printed geometries): Extraction Off and door closed (400-420 ppm), and extraction on/windows opened (380-400 ppm). This enabled a baseline correction reference for each sensor parameter in data.

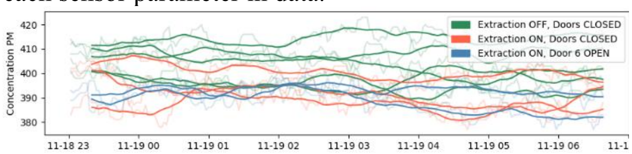

Figure 3. PM1.0 baseline identification in target location

Among the permutation of experiment variables under printing conditions, Figure 4 depicts the experiments for position 1 printer printing with PLA over a period of 1h:30'. Some conclusions of this plot are that extraction is confirmed to help with the clearance of the cabinet, both in concentration of PM and time for the concentration to decrease back to baseline after the end of the experiments.

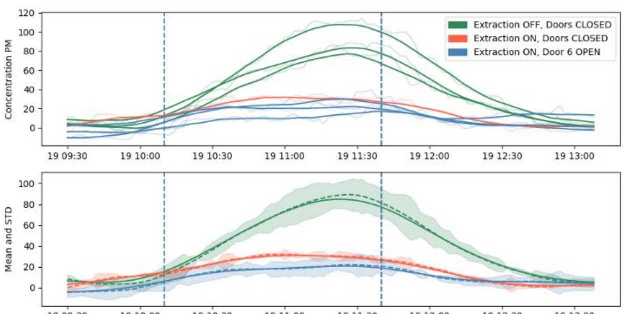

Figure 4. PM1.0 in target location under printing conditions

Having two different sensor manufacturers required repeating the analysis for repeated parameters. Sensors M1 were more reactive to changes in PM concentration than M2. Cross-manufacturer comparisons are required. Data collection is an iterative and cyclical process even with planning. Furthermore, some data collection impacted the selection of more sensors of Manufacturer M1 as well as the position (together with sensors M2).

Virtual sensing design implementation

Several models were selected both linear (e.g., lasso, elastic networks, Bayesian) and machine learning (e.g., boosted trees). Linear regression models have fair accuracy when supported by online measurements from hardware sensors (Stefaniak et al., 2021), whereas boosted trees have been used to estimate PM in (Koo & Yoon, 2022). A simple case is to remove the time variable of the series and estimate individual values based on the measurements of the reference low-cost hardware sensor in the same space, for which all linear models performed (Merino et al., 2023). This model lacks the capability of identifying trends since it is not based on time-series estimation.

Features selected for PM estimation are measurements of the same PM size from surrounding hardware sensors. For the simple case, the correlation between each of the PM variables (i.e., PM1.0, PM2.5, and PM10) is enough to train linear models when estimating single values. Thus, to estimate PM1.0 in sensor a target position, PM1.0 readings from all positions but the target are selected. This decision is in line with the purpose of the virtual sensor, to serve as a backup for and potentially replace the target low-cost sensor location (i.e., by the sliding door).

3D printer logs and low-cost hardware sensors required timestamp synchronization to compensate for the skew derived from internal clock drifts and different time server setups of the sensor and 3D printer platforms. Additionally, outliers identified (e.g., sudden jumps in raw signal or subsequent out-of-range measurements due to malfunction of PM and VOC sensors) are removed if the value is beyond two standard deviations. Uncontrolled data is discarded for the purposes of the virtual sensor. Finally, a Savitzky-Golay filter (Savitzky & Golay, 1964) was applied to smooth the curves. For the simplest case of the single-value estimations based on surrounding sensors, the time dimension is removed. Since the signals are previously synchronized that results into a set of arrays with values for each sensor position at a given time.

Models trained take the PM filtered and untimed arrays and having partitioned them into 80% training and 20% testing segmented sub-sets. Linear models R^2 scores reached 0.826 for Lasso, 0.826 for Elastic Networks, and 0.826 for Bayesian ridge for the simple approach. Non-linear approach using temperature and/or humidity as supporting estimators for both PM could not reach a significant R^2 score to be considered good estimators in a practical case, potentially due to the transformation into single-value estimation rather than time-series estimation, which enable trend identification and more accurate regression. Trained models can estimate the pollutant concentration in a specific point where the original low-cost sensor was positioned, therefore, they can be used to virtualize.

Virtual sensing deployment

The architecture published in (Merino et al., 2023) was designed to streamline virtual sensors training and operation. The architecture modularizes the process to facilitate data collection, preprocessing, training, model storage and loading, virtual sensor execution, and recalibration. In the simple approach for estimating PM based on surrounding sensors signals, the evaluation consisted in comparing the signal from the virtual sensor against the original sensor used to train the model after a period of dual operation (i.e., both the virtual sensor and the low-cost hardware sensor measuring PM values for a period of two weeks before replacing the hardware sensor).

The need for recalibration of virtual sensors can be identified by deploying a hardware sensor again in the original position. In a practical democratized additive manufacturing environment, or any other indoor building operation, hardware sensor may not always be available for recalibration, therefore, other approaches like (Koo & Yoon, 2022) may be more suitable.

Conclusions

Indoor air quality monitoring in democratized additive manufacturing environments is still not sufficiently explored. Virtual sensing approaches have demonstrated good performance for outdoors air quality and indoor comfort and pose a good opportunity to improve the awareness and control of hazardous pollutants. Beyond increasing awareness of emissions indoors at an affordable price, virtual sensors have the potential of informing ventilation systems operation to ensure operators safety while minimising building energy management. Virtual sensors can help understanding spatiotemporal distribution of emissions and emission flow into the rest of the built environment (e.g., adjacent offices, classrooms, or even bedrooms at home). Furthermore, IAQ monitoring can have the potential to inform on materials and design of indoor spaces as well as maintenance during the operation phase of the built environment (Abdalla & Peng, 2021).

This paper proposes a standard process for data collection and development of indoor air quality using virtual sensors in a practical democratized additive manufacturing environment, resulting of the analysis of the literature and the adaptations after the implementation in a practical democratized additive manufacturing environment. A simple example of a virtual sensor is explained throughout the implementation. The aim of the process is to facilitate the entry barrier to this technology to ad-hoc democratized manufacturing spaces, answering the research question. Additionally, the process should also address a second research question in the next iteration, on how to overcome lack of trust in low-cost monitoring and consequently in virtual sensing. Evaluation and calibration approaches should be investigated further to answer this question.

This process needs to be implemented in a set of case studies in similar democratized manufacturing spaces to test its validity and find adjustments. Additionally, a replication of this study in other democratized manufacturing environments would be beneficial for the confirmation of findings and to discover the casuistic across different setups and additive manufacturing technologies. Another limitation of this study is within the fact that indoor environments suffer from pollution from non-characterizable sources like outdoors pollution from construction sites or traffic. Case studies identified to complement this work in this direction and to ensure full transferability to the built environment context include domains like accommodation, offices, hospitals, universities, and public transport stations.

Abstract

Insufficient as-built data hinders the transition of the architecture, engineering and construction (AEC) sector to a circular system. Combining reality capture and machine learning (ML) could help better detect reusable components. However, a comprehensive image dataset of on-site inventory for circular economy strategies has yet to be developed. This study introduces and describes the generation of a purpose-built, 360°dataset. Initial validation using the YOLOv8 object detection model demonstrates a 63.4% mean average precision (mAP50), making it viable for computer vision. Further exploration of automating building stock inventory using 360-degree images and ML for urban mining is needed.

Introduction

The architecture, engineering and construction (AEC) industry must change from a linear to a circular system to minimize its harmful impact and meet climate targets. Reusing resources is a key circularity strategy for reducing waste (European Council and European Parliament, 2008). In the built environment, this strategy implies the non-destructive recovery and reuse of building components according to their original purpose without a loss in their value (Hillebrandt et al., 2018). The extensive reuse of building components is currently challenged by the lack of sufficient data about material and substance composition and the as-built condition of the existing building stock (Çetin et al., 2021; Iacovidou et al., 2018; Uotila et al., 2021).

Urban mining projects need detailed (digital) information on their composition and dimensions to reuse and recycle building resources efficiently (Çetin et al., 2021; Honic et al., 2019; Uotila et al., 2021). This as-built data needs to be generated in advance, typically using reality-capture techniques such as light detection and ranging (Lidar) (Gordon et al., 2023; Xiong et al., 2022), 360°cameras (Gordon et al., 2023), and public digital imaging mining using Google Streetview (Raghu et al., 2023). Digital data for information extraction is typically processed further using photogrammetry for extracting dimensions (Gordon et al., 2023; Xiong et al., 2022) and machine learning (ML) for determining the material composition of the building stock (Raghu et al., 2023).

Among reality-capturing technologies, 360°cameras proved to be the most viable technology for capturing reliable information for deconstruction purposes in a comparative case study, because of their high accuracy and low noise (Gordon et al., 2023). Panoramic images have advantages over planar photos because of their comprehensive view of spaces, device cost-effectiveness, and quick data capture (Barazzetti et al., 2018; Gordon et al., 2023; Chou et al., 2020). Furthermore, 360°images are increasingly used for quick image analyses in computer vision applications (Barazzetti et al., 2018; Gordon et al., 2023; Chou et al., 2020). However, computer vision and 360°images have yet to be combined for circularity strategies.

This research examines whether combining building inventory using 360 °cameras with ML can be used to detect reusable building components. Yet since ML applications are only as good as the training data on which they are trained (Géron, 2023), the quality of the dataset is paramount. The relevance of training data can be defined as the extent to which it aligns with the data that the model is likely to encounter in the production phase (Witt, 2023). This concerns what is depicted and how it is annotated. The quality of the dataset refers to aspects influencing the generalization capabilities of a model to unseen data. The generated dataset should be suitable for the application in terms of representativeness, image quality, dataset size, and variance (Géron, 2023). For the envisaged ML application, a real-world dataset that simulates a survey of end-of-life (EoL) scenarios is necessary.

However, in a preliminary field study we found that existing panoramic datasets of buildings are not suitable for the above application for the following reasons: they are either synthetically generated, they are a compilation of different scenarios without any repetition, they are limited to specific parts of buildings (e.g., the façade), they are too homogeneous in quality to be captured on-site, or they have only very broad labels (e.g., doors are not subdivided by function into entrance doors, emergency exits, or room doors)

Therefore, our study takes a first step towards using 360°panoramic images in reusability assessment by generating and validating a 360°image dataset in a case study on the Technical University of Dresden (TU Dresden) campus. The custom dataset ("TUDataset") is preliminarily validated using the state-of-the-art YOLOv8 object detection model to identify building components. The validation explores whether the data collected during an on-site audit is qualitatively sufficient for object detection applications. It also explores the differentiation of component types within a component category. In so doing, this

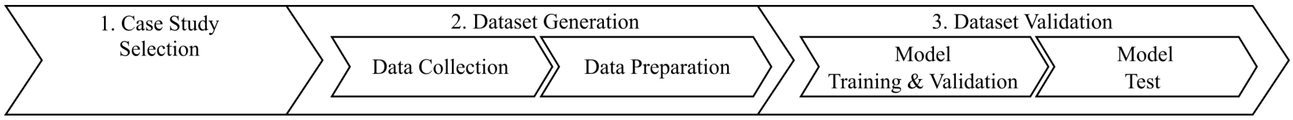

Figure 1: Research design of this study.

study gives valuable insights into the process of generating suitable 360°image datasets for building component reuse by discussing the chosen approach, potential for improvement, and next steps toward a full data-capturing ML pipeline.

Structure of the paper

The paper is structured according to the Figure 1. First, the following section describes the representative case study for EoL situations. It defines the data collection locations and the objects (i.e., the reusable building components) to be detected by the ML application. Second, the section "Dataset Generation" presents the approach and the image capture process to showcase how a 360°dataset can be created, and describes image processing for the specific use case of component reuse detection. Third, the "Dataset Validation" section describes how the approach is validated for computer vision. Experiments with the YOLOv8 object detection model verify the suitability of the dataset generation approach for the desired purpose of detecting reuse components. The methodology steps are presented in greater detail in the respective sections. Finally, the discussion reviews the contributions and further research steps toward a full pipeline of 360°image dataset creation for ML-based reuse detection.

Case Study Selection

As described in the introduction, the case study determines the relevance of the dataset for future input data from EoL buildings. The EoL refers to the final phase of a building's existence (after the production and use phase) in its current form (Hillebrandt et al., 2018). For this study, the case of "Technical University of Dresden (TU Dresden) campus" was chosen. It was designed to mirror urban mining projects by encompassing the entire building premises and emphasizing the frequent repetition of diverse building component designs within structures. It consists of five buildings on the TU Dresden campus that were selected according to the following considerations: around 32% of the residential and nonresidential buildings demolished in 2022 were built before 1948, 53% between 1949 and 1986, and only 14% between 1987 and 2010 (Statistisches Bundesamt, 2023). Accordingly, the case study was limited to the buildings on campus built between 1906 and 1990: two modern buildings, as well as three buildings of reform architecture from the early 20th century (see Table 1). Different EoL situations are presented: while the Beyer Building is partially gutted and currently unused, the Fritz-F¨ orster building is only partially in use due to renovation. The Nürnberger Ei and the Schumann building are contain operating offices and equipment (and, therefore, more data clutter).

Finally, only publicly accessible buildings were considered to comply with privacy compliance for publishing. Accordingly, the building was inventoried outside of business hours. People were asked to leave the field of view, and images with recognizable faces were removed during data cleaning.

Dataset Generation

While the relevance of the data was ensured in the design of the case study, the dataset quality (see Introduction) is addressed in the dataset generation process.

Data collection

A total of 1112 relevant images were captured for the case study (see 1). The data was generated from scratch using the specialized OpenExperience 360°camera helmet (Figure 2). The helmet has two installed 180°cameras, whose individual images are seamlessly merged into a spherical or panoramic view by a stitching algorithm. Capturing images in an onsite audit using a conventional 360°camera ensures that the data represents the expected input data. The final ML application is expected to generalize to input data collected under similar technical conditions.

The equirectangular projection (ERP) on a two-dimensional pane was used for the dataset. The ERP of the images has a resolution of 7000 × 3500 pixels, a horizontal and vertical resolution of 96 dpi, and a bit depth of 24 (see Figure 3). To address image variance deficiency observed in existing datasets, the data was captured at different times of the day and under varying weather conditions, resulting in different lighting and shading conditions. Furthermore, the images were taken without a fixed object distance, often capturing the same room from different positions and a person's viewpoint, generating a variance in the object's

appearance, scale, and occlusion. Finally, the strongly varied resolution of the images resulted in different representations of the same object.

Dataset Preparation

The generated raw data was prepared using the Roboflow[1] online tool through data cleaning, annotation, set partition, and pre-processing and augmentation further described below.

Data Cleaning

In object detection, images or videos are used as inputs, and the features are extracted from the information in the pixels. The selected YOLO (You Only Look Once) model employs a feature extraction method that does not require the prior definition and cleaning of features. Therefore, the data cleaning was limited to eliminating duplicates and excluding low-quality and blurred images.

Data annotation

Object detection is a supervised machine learning application that requires a fully labeled dataset for the training. What is recognized and the granularity of differentiation is determined in the annotation process.

The EU policy fails to provide regulations and prerequisites for the reuse of components without prior (destructive) testing. Thus, to determine what could be reused within the case study, a field search including online reused material marketplaces (Concular, Restado. Bauteilnetz, Ebay Kleinanzeigen, SALZA, and Bauteilclick), practice reports, and guidelines was conducted to identify building components categories with assumed general or ”default” reuse potential.

Table 2: Selection criteria for component identification.

Criteria	Description
Relevance in practice	The building components should be found in large quantities in every building.
Post-processing	The component should be reusable per default, with little refurbishment and no testing needed.
Typology	The components should have standard features, but different configurations. Shapes and colors should differ
Indoor	The availability of data demands a restriction to indoor components.

Because this study is a proof-of-concept, the scope of the object detection model was set to recognize only a selection of reusable components. To fit the ML requirements on representativeness, quantity, and variance, the selection criteria in Table 2 were developed. Out of the pool of default reuse components, five categories adhere to the established selection criteria: doors, windows, radiators, sanitary objects, and lights. These component categories are considered reusable without further destructive testing. They present a large intra-class variation (e.g., many different types of windows) and were captured in large numbers in the case study.

The next step determines the granularity of differentiation within the selected component categories. Existing indoor datasets, such as the PanoContext Zhang et al. (2014), Indoor360 Chou et al. (2020) etc., differentiate only in rough component categories, such as doors and windows. However, function, material, and design are decisive for component reuse. The selected reusable component categories, ”windows, doors, sanitary objects, and electrical

[1]https://roboflow.com/

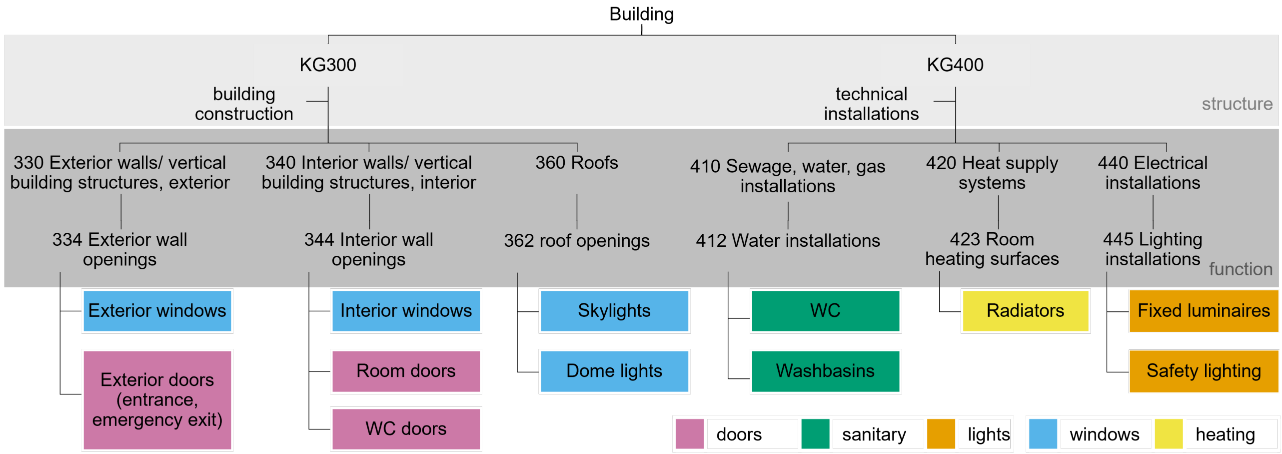

Figure 4: Categorization of reusable component selection according to DIN276.

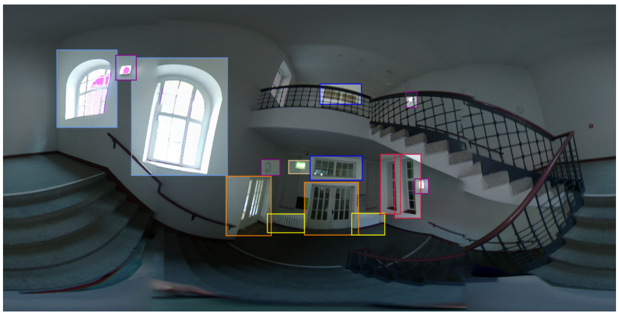

Figure 5: Each image label has a different bounding box indicating different component types.

installation", needed further differentiation to meet these requirements.

This study used the German AEC sector's building cost structure of the national standard DIN 276:2018-12 (Deutsches Institut für Normung, 2018) as a reference for the annotation. The component selection (windows, doors, plumbing, lights, and heating) was further differentiated into cost groups according to their associated building structure and function within the building or system, as seen in Figure 4. Categorization by cost group will not only standardize the work in different projects by reference to a public standard, but it could also allow for rapid cost determination for selective reconstruction.

In the annotation, the selected reusable component categories were set as super-categories, and the different cost groups were set as component classes. Furthermore, the component types were differentiated within these classes according to the material and design. For example, if the frame materials differed, two external glass doors with the same design would belong to different types. Hence, the labeling was structured according to component category, class (e.g., exterior door), and type (e.g., type 21). This resulted in 136 labels, ergo, different component types.

Dataset Partition

This study employed hold-out validation. It is an evaluation technique in which the dataset is split into three subsets: training, validation and test set. The training set is used to fit the models, the validation set is used to estimate the prediction error for model selection, and the test set is used to assess the generalization error of the final model configuration. The test data set is "held-out" and only used once, as reusing it can result in a substantial underestimation of the true test error. The TUDataset images were therefore divided into 70% training (792), 20% validation (226), and 10% testing (116) images.

Data pre-processing and augmentation

Applying pre-processing techniques to the training, validation, and testing sets ensures that the machine learning model learns and infers based on consistent image properties. Inference refers to the process of generating predictions.

First, the images were auto-orientated, removing the EXIF (Exchangeable Image File Format) data from images to ensure that they are displayed in the same manner as they are stored on the disk. Then, the image size was stretched to 640 × 640 pixels. Finally, the last step consists of data augmentation or training set expansion. This technique artificially increases the training set size and is a regularization method, reducing overfitting. To improve the model's tolerance to position, orientation, and size changes, the augmented instances should be as realistic as possible and ideally be indistinguishable from non-augmented instances by the human eye. Following Zhao et al. (2021), several augmentation techniques considering the particularity of the equirectangular projections were applied to the training and validation sets: the images were flipped horizontally and sheared $\pm$ 15°horizontally and $\pm$ 15°vertically both on the image level and bounding box level (see Figure 7). The outputs per training sample were set to 3, creating three altered images for every instance and resulting in a final dataset size of 2718 (3 × 792) images.

Dataset Validation

After generating the dataset, the suitability of the onsite 360°images for computer vision methods, and con-

sequently for ML-aided reusability assessment, was validated using an object detection model.

The use of 360°images poses specific challenges for object detection. The projection of the spherical image to a plane distorts the objects depending on their distance and angle to the camera viewpoint. Integrating optimized distortion-aware convolution layers could handle these geometric deformations (Li et al., 2023). However, for the purpose of this proof-of-concept study, the conventional state-of-the-art object detection model YOLO (Redmon et al., 2016) was deemed appropriate. Different versions of this one-stage-detector have already been applied in the field of object detection in 360°images (Chou et al., 2020; Yang et al., 2018), as well as being frequently used as a benchmark model (e.g. in Zhao et al. (2019, 2020)). Due to constraints on Graphics Processing Unit (GPU) capacity, the Yolov8s model pre-trained on the COCO dataset (Lin et al., 2014) was selected.

Model Training

This study adopted an iterative training and validation process proposed by Géron (2023): the training configurations were tweaked based on the performance on an independent validation set to avoid overfitting, wherein a model becomes excessively optimized for the test set and fails to generalize to novel data. The model was evaluated on the test set only after selecting a final configuration. This iterative strategy is simplified in Figure 6. The training runs, and their validation and final testing were locally implemented in PyTorch using an NVIDIA RTX A4000 GPU.

The training process for the YOLOv8 model aims to minimize the training and generalization errors. In each run, the cost or loss function compares the predicted bounding box outputs with the actual outputs on the training set (training loss) and the validation set (validation loss). The generalization error is calculated as the difference between validation and training losses and is a key metric indicating the model's ability to perform well on new, unseen data.

The model's training performance, speed, and accuracy depend on using various hyperparameters and configurations that need manual configuration. This study adopted the validation approach proposed by Smith (2018) that examines the learning rate, batch size, momentum, weight decay, cyclical learning rates (cosine learning rate scheduler), and cyclical momentum. Accordingly, training and validation loss are analyzed during training to detect indications of underfitting and overfitting and determine the optimal combination of hyperparameters.

An initial configuration was used as a benchmark to adjust the training arguments, i.e., learning rate, batch size, momentum, weight decay, cyclical learning rates (cosine learning rate scheduler), and cyclical momentum. Nine configurations were trained and validated. The models were assessed by their mean average precision (mAP), precision, recall, and F1 score. A final configuration with the following hyperparameters was selected: a learning rate of 0.0007, weight decay of 0.001, the use of a cosine annealing learning rate scheduler, dropout regularization, and the Adam optimization algorithm.

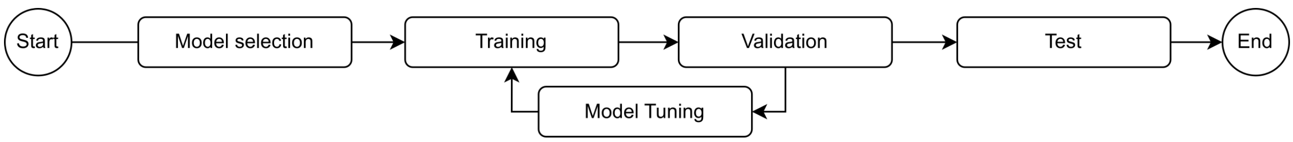

Figure 6: The applied iterative model training approach.

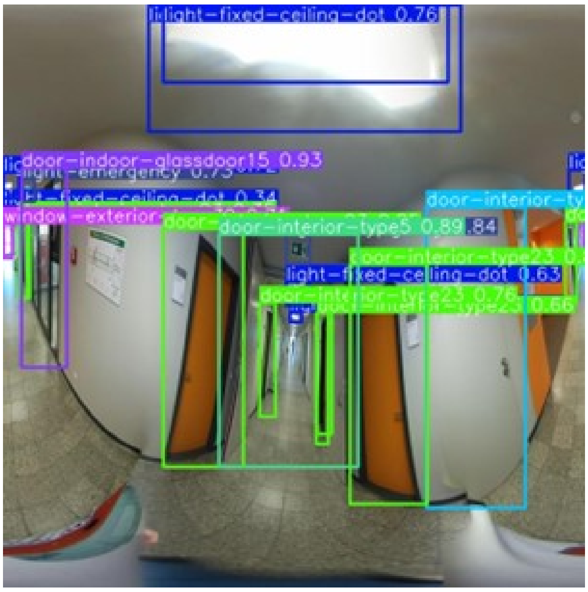

Figure 8: The model output with colored bounding boxes according to their label and superscribed with the confidence of the selected label.

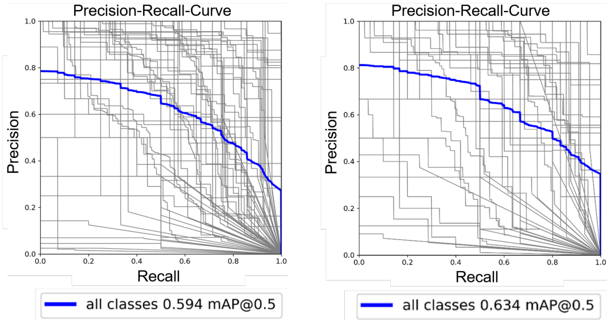
Model Test

Finally, the chosen model configuration is tested on the hold-out test set, and its metrics are evaluated. The test run was performed on the test subset of 116 images and 975 instances. An example of the model's output in the test run can be seen in Figure 8. The model achieved an mAP at an intersection over union (IoU) threshold of 0.5 (mAP50) of 0.634, indicating a satisfactory overall performance in correctly detecting and localizing objects (see Table 3).
Furthermore, precision and recall have higher values than in the validation (see Figure 9). The PR curve reveals that a significant number of class labels exhibit a comparatively high PR score, indicated by the curves above the blue average PR score line, and a subset of classes with considerably inferior PR curves. This combination leads to an overall mAP@50 of 63.4% for all classes.
It indicates a model demonstrating relatively high precision at the beginning and overall good performance in precision and recall trade-off. In the class-wise evaluation of the model, in the worst-performing classes, zero instances were detected, resulting in low precision, recall, and mAP scores. This indicates that the model does not effectively detect and localize instances of these classes. These classes may have visual attributes that are difficult for the model to distinguish, leading to recognition errors. Furthermore, insufficient training data for these classes could also contribute to poor performance, as the model is not sufficiently exposed to different examples for effective learning.

Table 3: Test set performance metrics.

Class	Images	Instances	Box(P	R	mAP50	mAP50-95)
all	116	975	0.721	0.596	0.634	0.371



(a) Precision-Recall-Curve in training
(b) Precision-Recall-Curve in test-run

Figure 9: Performance metrics of the test run.

The diagonal in the confusion matrix (Figure 10) suggests that most classes are confidently predicted. However, the outliers indicate that some classes are incorrectly assigned to another specific class with high confidence. This can be recognized by a single point in a row and the coloring of the point in the graph. For these classes, more images or higher quality images are needed so that the model extracts features that lead to differentiation from the other component types more efficiently. Certain classes, such as class 135 (window-interior-type8) and class 136 (window-interior-type9), lack fundamental distinguishing features, which is visible in the erroneous assignment to very different component types (doors, lights, windows).

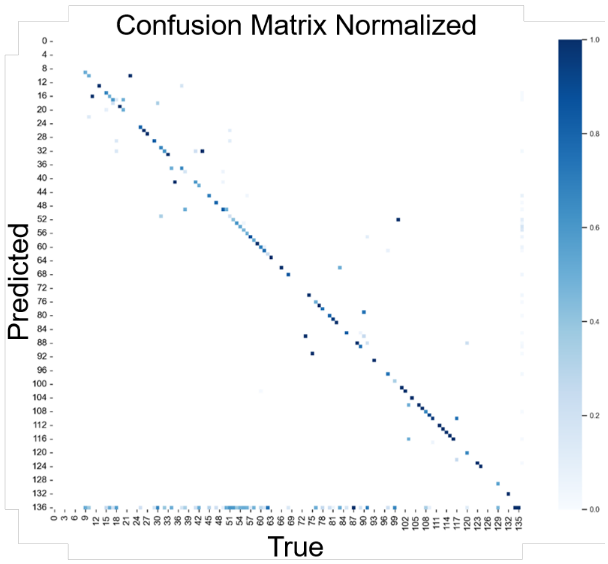


Figure 10: Normalized confusion matrix in test-run. Class IDs 1–52 = door types, 53–59 = lights, 60–64 = sanitary objects, 65–136 = window types.

Discussion

The implemented YOLOv8 object detection model shows that satisfactory accuracy can be achieved using conventional object detection models on equirectangular projections for differentiating component types within a class. The test metrics indicate effective assignment to building component categories (see Fig. 4), with most errors occurring in differentiating component types within the same component class. For instance, misclassified windows are mostly labeled as another window type rather than a different class, like doors or lamps. The model's overall performance indicates that the differentiation into different component types needed for the reusability assessment is possible. However, refining misclassifications, minimizing false positives and negatives, and augmenting training data for complex classes would improve its accuracy in recognizing component types.

A limitation of this study is the component-level annotation, which is time-consuming and, thus far, only includes component types from the case study. Using the object detection model trained on the TUDataset for other buildings will face challenges in detecting new building component types. Therefore, for subsequent research, the dataset annotation will be edited to be broader by eliminating further typification according to design and material. Only the categories of the DIN276 (see Figure 4 should be considered: e.g., exterior windows, skylights, dome lights, exterior doors (entrance, emergency), interior doors (room doors, WC doors), toilets, sinks, radiators (vertical, horizontal), lights (fixed luminaires), and safety lights. Combining existing labels into broader ones will introduce further intra-class variation, promising a better generalizing model and ensuring applicability to new buildings and EoL situations. While a simplified annotation process is considered to facilitate the up-scaling of the proposed approach to further building inventories, future studies to assess and validate scalability to other building contexts and larger datasets are needed.

This study aimed to detect the component category and type. However, more as-built information, such as the components' dimensions, material, and condition, should be extracted for reuse assessment. Therefore, photogrammetry and further feature extraction will be explored in upcoming research.

Furthermore, this study only used the object detection model to validate the approach. Further research will focus on the functionality and performance of the model. Different established object detection models should be compared in terms of robustness in dealing with large datasets and detection performance for the final model selection. Furthermore, various approaches integrating spherical layers into convolutional neural networks have been proposed in research (Cohen et al., 2018; Li et al., 2023; Zhao et al., 2019). Considering these additional models is promising for effectively addressing the distortions in ERP images and potentially improving the detection performance.

Finally, some limitations stem from the case study selection. First, resource constraints required a limitation on the included architectural styles, potentially compromising the generalizability of the results to buildings from different eras. Therefore, the selection criteria should be reviewed to integrate diversity of architectural styles and building functionalities, and the TUDataset should be continuously adapted to represent the variety of existing building stock. Second, the selection of component categories examined in this research represents only a small subset, and a broader range of non-destructive, non-toxic component categories could potentially be reintegrated into a circular economy. Third, it is based on the assumption that all areas and spaces within a building are accessible. Consequently, only the components captured by the camera can be identified. Therefore, the data introduces uncertainties in the number of components similar to those in traditional on-site inspections and component identification processes.

Conclusion

The main contribution of this research is the introduction of an approach to generate well-suited 360°image datasets for circular component reuse. The selected case study, centered around five buildings on the TU Dresden campus, served as a representative scenario for end-of-life sites. The dataset generation process involved using a specialized OpenExperience 360°camera helmet, capturing 1112 relevant images at different times of the day and under varying weather conditions. Data preparation, including cleaning, annotation, set partition, and pre-processing, was conducted to ensure the technical and relevance requirements of datasets.

The resulting fully-labeled TUDataset consists of approximately 2,400 panoramic images in equirectangular projection and 136 object classes, facilitating research and practical applications in object detection. Data quality and relevance requirements were addressed in the case study's design and during the dataset generation process. The YOLOv8 object detection model validated the real-world dataset, achieving a mAP50 of 0.634 on the test set.

The workflow developed in this research can be extended to other reusable building components, thereby contributing to developing new cost-effective and scalable approaches for building component recovery. Exploiting machine learning and 360°images for the inventory and reuse assessment could save time and costs, making circular strategies more competitive.

Overall, this study demonstrates that 360°images generated on site are suitable for effectively detecting different building component classes (windows, doors, sanitary, lamps, radiators), and provides the foundation for the next steps toward automated reusable component detection.

BENCHMARK FOR TOPOLOGICAL AND SPATIAL ASSESSMENT OF INDOOR RESIDENTIAL BUILDINGS

Abdullah Elsafty[1], Timo Hartmann[1]
[1]Civil System Engineering, Technische Universität Berlin, Germany
a.elsafty@tu-berlin.de

Abstract

Our paper introduces a new benchmark for evaluating indoor residential buildings, addressing the lack of standardization in building assessment methods. Utilizing laser-scanned point clouds, we capture diverse architectural styles, enhancing accuracy in maintenance, navigation, and safety planning. Our approach, underpinned by precise reference models and metrics, allows for comprehensive method comparisons. The accompanying datasets ensure reproducibility and wide applicability. This benchmark, available publicly, fosters collaborative research and advances building assessment techniques, ultimately improving the resilience and sustainability of residential structures.

Introduction

In the domain of building assessment, understanding, and analyzing indoor residential environments is crucial. These environments, central to daily human experiences, are characterized by a myriad of spatial and topological complexities (Zhang *et al.*, 2022).

Accurate spatial analysis is vital for effective space management, enhancing living comfort and functionality, while topological assessment is crucial for efficient navigation, particularly in emergencies, to ensure safety and accessibility. The point cloud technology marks a significant leap in accurately representing these environments. With its ability to provide precise 3D representations, point cloud offers an unprecedented level of detail and accuracy(Cheng *et al.*, 2018). This advancement has facilitated more realistic modeling of indoor environments, impacting fields ranging from architectural design to emergency planning (Gankhuyag and Han, 2020; Guo *et al.*, 2021).

Despite its importance, the field of building assessment faces significant challenges, primarily due to a lack of comprehensive and precise benchmarks specifically tailored for residential buildings. Existing methods and datasets often fall short in capturing the unique complexities and diversity inherent in residential environments (Chen *et al.*, 2023). This gap in accurate and scalable representation and assessment tools hinders advancements in architectural design, maintenance, and safety planning, ultimately impacting the efficacy of residential space utilization.

Our research addresses this critical gap by introducing a novel benchmark for the topological and spatial assessment of indoor residential buildings. Utilizing advanced laser-scanned point cloud datasets, this benchmark is meticulously crafted to capture diverse architectural styles and layouts of residential environments. The primary objective is to provide a robust and versatile tool that enhances the accuracy and comprehensiveness of building assessments, thereby facilitating effective maintenance, navigation, and safety planning in residential spaces.

In developing this benchmark, we employed a multifaceted approach that integrates various scanning technologies and environmental conditions. This approach ensures a broad and realistic representation of residential spaces, reflecting the complexities encountered in real-world scenarios. The benchmark's methodology emphasizes the precision, accuracy, and chromatic fidelity of the point cloud data, making it a highly reliable resource for evaluating building assessment methodologies.

Our primary goal is to bridge the existing research gap by offering a new database and robust evaluation metrics. This benchmark, featuring diverse point cloud data, is designed to advance algorithms tailored for residential settings, contributing to more efficient and accurate building maintenance, safety planning, and architectural design, ultimately enriching residential living spaces. This paper is structured as follows: Section 2 provides a detailed review of related work addressing the study foundation. Section 3 discusses the benchmark setup, from data acquisition to evaluation. Finally, Section 4 concludes the paper, summarizing our contributions and suggesting directions for future research.

Point of Departure

In this section, we discuss existing datasets and benchmarks in the field of residential indoor building assessment, specially from laser scanning. This frames our study within the broader landscape of architectural technology and highlights the value of our research focus. In the exploration of indoor datasets, various collections have emerged, each with unique attributes and limitations. ISPRS dataset (Khoshelham *et al.*, 2017) emerges as a notable collection, focusing on indoor modeling through point clouds, while rich in indoor point cloud data from varied environments like universities and a fire brigade office, presents certain limitations for our research focused on residential environments. The dataset's emphasis on institutional settings differs markedly from the complexities inherent in residential spaces, making it less applicable for studies centered on residential layouts. Similarly, the ScanNet dataset (Dai *et al.*, 2017) and the SceneNN dataset (Cheng, Meng and Sun, 2020) have made strides in capturing a range of indoor scenes. However, most of their scans are constrained to one or two rooms. This limitation significantly hinders their applicability in the domain of scalability, where a broader understanding of entire residential units is essential.

The ETH3D dataset [13], for instance, includes a modest collection of 16 indoor scans. While valuable for multi-view stereo applications, its limited scope and primary focus on stereo rather than 3D point-cloud processing render it less suitable for our scope. Contrasting with real-world data, the SUNCG dataset (Song *et al.*, 2017) offers a synthetic alternative, presenting a wide array of indoor scenes with CAD-quality geometry and annotations. However, the synthetic nature of SUNCG means it cannot fully capture the complexity and unpredictability of real-world residential settings, a crucial element for authentic floorplan generation.

Diverging from these, Floor-SP (Chen *et al.*, 2019) and Matterport3D (Yadav *et al.*, 2022) bring RGBD image sets. Matterport3D dataset brings forth high-quality panorama RGBD image sets encompassing 90 luxurious houses. While offering rich visual data, its format and focus do not align with the specific needs of laser scanning. In a similar vein, the Stanford 2D-3D-S dataset (Armeni *et al.*, 2016) provides large-scale scans of office spaces using the same Matterport camera technology. Despite its scale, the dataset's emphasis on 2D and 3D semantic annotations does not address the nuanced requirements of residential environments.

Among these, the Floor-NET dataset (Liu, Wu and Furukawa, 2018) stands out with its provision of full floorplan annotations and corresponding RGBD videos from smartphones for 155 residential units. Despite its closer alignment with residential applications, its format and the mode of data collection may pose challenges in scalability and accuracy when applied to broader residential scenarios. In addition to these datasets, numerous ad-hoc datasets have been developed (Fang *et al.*, 2021; Tang *et al.*, 2022; Kim and Lee, 2023), each tailored to specific tasks or applications. While these datasets contribute valuable insights to their respective areas, their specialized nature often limits their utility in a broader context, particularly in studies focused on scalability and general applicability in residential environments.

This examination of various indoor datasets underscores a prevalent issue: while numerous datasets provide valuable insights into indoor environments, they notably lack in addressing the comprehensive needs of residential building representation. A key challenge is the absence of datasets offering extensive scans of real-world residential spaces, including furnishings, a gap often attributed to privacy concerns. Moreover, the tendency for many datasets to be ad-hoc or overly specialized limits their utility in research focused on scalability and broad applicability in diverse residential settings. Considering these limitations, our research introduces a novel benchmark utilizing laser scanning (point cloud) technology. This benchmark is specifically designed to capture the intricate details and complexities of residential buildings, addressing the critical need for a more accurate and scalable approach in the topological and spatial assessment of indoor residential environments. This advancement not only fills a significant void in the current research landscape but also sets a new standard for precision and comprehensiveness in the field of building assessment.

Benchmark Setup

Benchmark dataset

In constructing this benchmark, we implemented a wide selection process for point cloud data, adhering to meticulously defined criteria to ensure a comprehensive and accurate depiction of a variety of residential buildings. This evaluation focused on key factors such as precision, accuracy, chromatic fidelity, and the granularity of details within individual data points.

We also prioritized diversity in data acquisition methodologies, incorporating a range of scanning technologies and environmental conditions to authentically mirror complex, real-world data collection scenarios. Moreover, the curation of point cloud content was strategically executed to encompass a wide array of residential spaces, each with their unique architectural styles and spatial layouts. Table 1 delineates these point cloud specifications and criteria. First, we classify the criteria into three main categories: point criteria (PCr.), scan condition (SCd.), and scan content (SCt.). then, accuracy, colors, number of points in millions (No.), and sensor type were added to the point criteria. Acquisition complexity (AC) and moving objects (MO) were added to scan condition category. Finally, building type (BT) and furniture (F) were added to the scan content. This systematic approach in dataset compilation not only addresses the shortfall in publicly available datasets but also establishes our benchmark as a model of versatility and practical applicability in residential building assessment.

Table 1:Point cloud data criteria

		D1	D2	D3	D4	D5
PCr.	Acc.	6-8 mm				1 cm
	Color	✓	✓	x	✓	✓
	No.	316	321	319	6.6	252
	Sensor	TLS / MLS		TLS	MLS	TLS
SCd.	AC	✓	✓	x	✓	✓
	MO	x	x	x	x	✓
SCt.	BT	H	H	H	D	A
	F	✓	✓	x	✓	✓

Our dataset includes a curated selection of five residential environments, each representing different living settings and contexts. It features datasets from a multi-floor house (D1, D2), offering an urban residential perspective with challenges like clutter, occlusions, and elaborate interior designs.

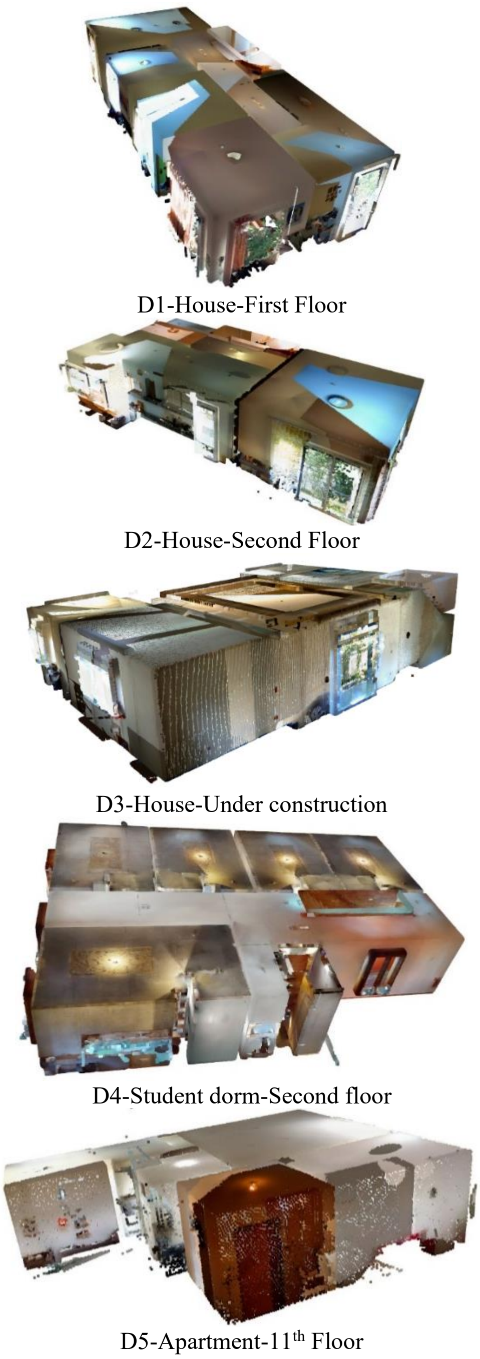

Figure 1:Point cloud data screenshots.

An additional dataset from a fully furnished apartment (D5), situated on the 11th floor, showcases the intricacies of high-rise living environments. We also included a ground floor dataset from a house under construction (D3), highlighting the complexities of unfinished architecture. Complementing these, a dataset from the second floor of a fully furnished student dormitory (D4) adds to the architectural and contextual diversity. Figure 1 provides a visual representation of these diverse point cloud data.

For data acquisition, we employed both Terrestrial Laser Scanning (TLS) and Mobile Laser Scanning (MLS) methodologies, tailored to the specific characteristics of each residential setting in our dataset. The Trimble X9 TLS system, renowned for its extensive range and high precision, was used, achieving an exceptional accuracy of 8 mm, particularly in interior scans. In contrast, for the dormitory dataset (D4), we utilized the MLS capabilities of the iPhone’s LiDAR sensor, which offers suitable navigation and accuracy (±1 cm) within apartment spaces (Luetzenburg, Kroon, and Bjørk, 2021). Notably, datasets D1 and D2 were captured using a combination of TLS and MLS technologies, leveraging the comprehensive range of the Trimble X9 and the agility of the iPhone's LiDAR sensor. This dual-technology approach for D1 and D2 ensures a richly detailed representation of the intricacies inherent in residential spaces.

Table 2 provides detailed technical characteristics of these two scanning devices. By integrating both TLS and MLS methods, our benchmark accurately reflects the varied challenges and scenarios present in residential buildings, demonstrating the efficacy and adaptability of diverse laser scanning technologies in different residential contexts. Contrasting with many existing benchmarks that typically engage in preprocessing to remove noise and reflections, our benchmark adopts a novel approach. We emphasize the importance of preserving and incorporating indoor noise elements within each residential space. This decision stems from our understanding that noise, particularly in indoor environments, is an inherent characteristic of real-world data. It offers valuable insights into the everyday use and dynamics of residential spaces.

Table 2: Laser scanners technical characteristics

Specs.	TLS	MLS
Range	120 m	3 m
Accuracy	6 – 8 mm	± 1 cm
Acquisition time (one floor)	60 min	3 min

Reference models

In the development of our benchmark, a fundamental component was the construction of models using Autodesk Revit™. This step involved the detailed creation of 3D models that are essential in residential buildings. While our primary focus was on the 3D models themselves, these models inherently facilitate the generation of crucial elements like adjacency graphs, navigation plans, and evacuation paths. As depicted in Figure 2, these models provide a comprehensive foundation for understanding and analyzing the spatial and topological aspects of residential environments. By focusing on 3D modeling, we ensure that the essential characteristics of residential buildings are accurately captured, laying the groundwork for subsequent analytical processes that are vital in assessing and understanding the dynamics of these spaces.

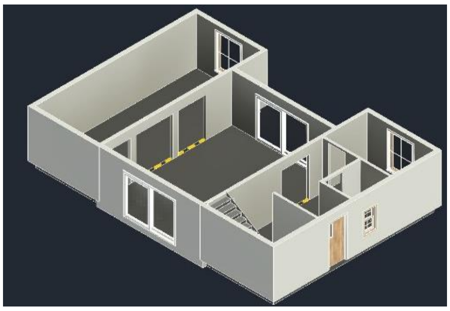
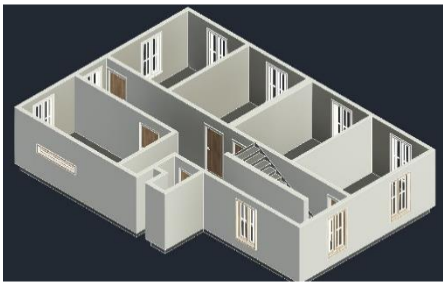
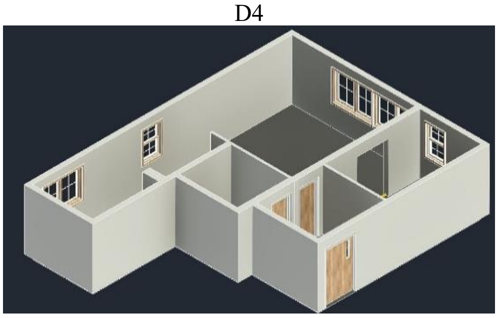
D2



D3



D4



D5

Figure 2: 3D reference models.

In the geometric reconstruction phase, we undertook a series of systematic procedures. These included adjusting levels, constructing walls, and other architectural elements, and integrating doors, windows, and circulation components. Notably, this reconstruction process did not rely on manual on-site measurements but solely on the precision inherent in the point cloud data. This strategy highlights the effectiveness of modern scanning technologies in accurately capturing indoor residential environments. By depending exclusively on point cloud data, our reference models not only demonstrate the capabilities of advanced scanning technologies in building assessment but also challenge the traditional dependency on labor-intensive manual measurement methods.

Additionally, it is crucial to address the concept of 'ground truth' within the context of point cloud processing. Typically, 'ground truth' refers to a model manually constructed in software, representing an 'as-built' or 'as-is' scenario. While these models are highly accurate, they are not without limitations. In our benchmark, these models are utilized more as a comparative standard rather than an absolute ground truth. They provide a robust and reliable foundation for evaluation but are acknowledged as not being infallible. This nuanced understanding of 'ground truth' is fundamental in our approach, ensuring that our benchmark provides a realistic and practical standard for evaluating the performance of various methodologies in the realm of residential building assessment.

Evaluation metrics

In our benchmark, specifically designed for topological and spatial assessments in residential environments, we incorporate a range of tasks including area measurement, floorplan generation, adjacency graph construction, navigation, and evacuation planning. Recognizing the integral role of geometric evaluation in understanding topological and spatial data (Pintore *et al.*, 2020), our metrics also encompass the assessment of geometric accuracy in reconstructed models. This approach ensures a thorough evaluation of algorithm performance beyond just computational efficiency and automation level, with a focus on the quality of algorithms in relation to indoor residential environments.

For geometric accuracy assessment, we utilize the Root Mean Square Error (RMSE), a well-established statistical measure in spatial data analysis (Li *et al.*, 2017). RMSE quantifies the variance between predicted and observed spatial dimensions, thereby evaluating the precision of area measurements in a reliable and quantifiable manner.

In evaluating floorplan generation, our benchmark employs accuracy metrics: Recall, Precision, and F1-score. These metrics, prevalent in pattern recognition and information retrieval, offer a multidimensional perspective on the accuracy and completeness of generated floorplans (Kim and Lee, 2023).

To address the evaluation of topological relations and spatial assessments, such as adjacency graph construction, navigation, and evacuation planning, we adopt a dual approach. **Qualitatively**, usually experts conduct a visualization evaluation, subjectively assessing the clarity, accuracy, and usability of the representations (Knauff, Rauh and Renz, 1997). **Quantitatively**, we implement graph similarity measures, like graph edit distance, to evaluate topological relations. This measure calculates the minimum number of edits needed to transform one graph into another, thus gauging the fidelity of the algorithm-generated graphs compared to our reference models. Additionally, spatial accuracy metrics should be employed to assess deviations in spatial configurations, and consistency checks are conducted to ensure the logical coherence of spatial arrangements. This combination of subjective and objective evaluations forms a comprehensive assessment framework, capturing both the perceptual quality and the measurable accuracy of spatial models in residential environments.

Accessibility and Participation

In line with our commitment to collaborative scientific progress, our benchmark will be made publicly accessible. We invite scholars, practitioners, and members of the scientific community to engage with this dataset, which will be available for download from the Deposit once Repository. This open-access initiative is designed to stimulate comprehensive utilization and analysis of the dataset, thereby contributing significantly to advancements in the field.

We strongly encourage scholarly engagement from researchers interested in applying and investigating various methodologies and algorithms with our database. This invitation extends to a diverse spectrum of researchers from both academic and industrial spheres. We advocate for the exploration of a wide range of application scenarios, including emergency response planning and architectural design. The insights gained from these explorations are expected to be invaluable in enhancing our understanding of current algorithmic capabilities and limitations and could lead to innovative developments in the field.

We are introducing a set of guidelines for its effective use and implementation. These are designed to bridge the gap between theoretical research and practical application, providing clear, actionable steps for accessing and utilizing the benchmark. Users can navigate the point cloud raw data and reference Revit files via the repository, enabling straightforward integration into their projects. For each specific application, practitioners are encouraged to refer back to this paper for the relevant proposed evaluation metrics to ensure accurate and effective application. This commitment to support aims to foster a collaborative environment, encouraging the widespread adoption and application of the benchmark across various professional domains.

Conclusion

This research has established a new benchmark for the topological and spatial assessment of indoor residential buildings, an area that has been inadequately represented in existing datasets. By incorporating a variety of point cloud data acquired through laser scanning, this benchmark serves as a crucial tool for the precise evaluation of algorithms related to this domain. Our benchmark, anchored in constructed reference models, provides a solid criterion for both geometric and topo-spatial assessments. This addresses significant gaps in existing methodologies and sets a new standard in the field. Looking forward, this benchmark opens the door to a multitude of research avenues and practical applications, marking a significant advancement in the field of spatial data analysis. Its potential extends across various domains, from enhancing emergency response strategies to innovating architectural design and urban planning. A key direction for our future work will involve conducting real-world case studies to present and validate the practical applicability and effectiveness of our benchmark across a diverse range of architectural styles and environments. we will illustrate how the application of our benchmark can lead to tangible improvements in building performance, such as increased energy efficiency, improved occupant well-being, and reduced environmental impact, thereby fulfilling our vision of fostering more sustainable and resilient living environments. The benchmark is poised to be a cornerstone in the development of more accurate and efficient algorithms, fostering interdisciplinary collaborations that blend expertise from architecture, urban planning, data science, and beyond. Additionally, it offers a platform for integrating emerging technologies like augmented reality for immersive visualizations and AI to develop advanced evaluation metrics, we aim to set new standards in spatial analysis, ensuring our benchmark remains at the forefront of architectural assessment and urban planning. While our dataset encompasses a variety of architectural styles, we aim to expand its diversity by incorporating more settings, featuring unique design elements and circulation patterns, to enhance its applicability. Also, by integrating socio-cultural aspects, recognizing the impact of social norms and cultural values on residential architecture. This inclusion will allow our benchmark to evaluate and guide the design of spaces that are not only physically sound but also resonate with the cultural and social fabric of their communities more accurately. In addressing the limitations of our benchmark, we acknowledge challenges in the acquisition of point cloud data for complex residential indoor environments, like furniture, which may not fully capture the intricacies of such spaces. However, this journey also invites us to confront and navigate the challenges and limitations inherent in such pioneering work, ensuring continuous improvement and relevance in an ever-evolving landscape.

Acknowledgments

We acknowledge the support of the ReconTOP project, and the funding provided by the Deutsche Forschungsgemeinschaft (DFG), which were crucial in the realization of this research.

EXPLAINABLE ARTIFICIAL INTELLIGENCE IN GENERATIVE DESIGN FOR CONSTRUCTION

Sanaz Zarghami[1], Hanieh Kouchaki[2], Longzhi Yang[1] ,and Pablo Martinez Rodriguez[1]
[1]Northumbria University, Newcastle, United Kingdom
[2]Tabriz Islamic Art University, Tabriz, Iran

Abstract

As artificial intelligence rapidly advance, their growing complexity enables more sophisticated applications across sectors, including construction. However, the opaque nature of algorithms, such as generative AI, reduces human interpretability and trust. While providing benefits like enhanced efficiency, generative design's black-box processes hamper adoption. Explainable AI can elucidate how AI algorithms generate outputs, thereby improving understanding and confidence. Despite explainable AI's potential, construction has given it limited focus. This research systematically reviews the application of explainable AI in generative design in construction, with an aim to allay risks and enable wider utilization of these emerging technologies for improved engineering design.

Introduction

The expanding integration of artificial intelligence (AI) in the field of architecture and construction, driven by the exponential growth in data, is reshaping traditional practices. The manual analysis of vast datasets and reliance on rule-based computing methods pose challenges, prompting the adoption of AI for systematic data analysis through predictive modeling. This transformation influences various facets of the industry, including architectural and structural design, construction safety, sustainability, affordability, speed, return on investment, and operational performance. Generative design, a departure from traditional methods, empowers computers to semi-autonomously explore design spaces, presenting designers with diverse options for analysis and consideration (Baduge at al., 2022; Junk and Burkart, 2021; Krish, 2011).

While the adoption of AI in construction is gaining recognition, challenges arise in understanding and interpreting AI model outputs, often considered "black boxes". Concerns about bias, fairness, trust, and reliability, particularly in critical domains such as recruitment, real-time progress monitoring, cyber-security, risk management, and safety, warrant attention. Human decision-making in these domains is also susceptible to bias, and the reluctance to embrace AI is often rooted in a lack of understanding. Establishing trust in AI models, crucial for widespread acceptance, is explored through explainable artificial intelligence (XAI). This involves methodologies and processes to enhance comprehension and confidence in the outcomes and outputs of AI algorithms, addressing the industry's need for transparency and reliability (Matthews et al., 2022; Gunning et al., 2019; Sokol et al., 2022; Love et al., 2023). While XAI has gained traction in fields like law and medicine , its exploration in construction remains limited despite the rise of generative AI.

This study aims to fill this gap by providing a thorough exploration of XAI for generative design in construction. Through a systematic review, this paper advocates for generative AI in construction, raises awareness of XAI limitations and gaps, and harnesses its advantages. To achieve this, the study provides comprehensive answers on how XAI tackles transparency and bias, differentiates generative AI, elucidates the mechanisms of XAI for generative design in construction, and examines how XAI influences the generative design framework in this industry.

Methodology

The methodology employed in this study aims to provide a comprehensive analysis of the research objectives. In essence, this paper begins by elucidating the fundamentals of AI followed by a systematic review of 31 academic papers on generative design and the emerging field of generative AI design. In essence, drawing from the mentioned comprehensive review, this section has been concluded by presentation of a categorization of generative design techniques, methods, and models. Subsequently, the concept of XAI is introduced and to enhance the clarity, terminologies are provided, outlining its significance and methodologies. This section derives from an analysis of 30 academic papers to establish a taxonomy for the preliminary stages of applying XAI. Moving forward, the paper conducts a critical review of the construction industry, focusing on the potential applications of generative AI within this domain. Illustrative examples of generative processes in architectural design further enrich the discussion. Finally, the paper proposes a comprehensive taxonomy titled "Explainable Generative AI Design," defining various approaches to render generative design algorithms interpretable and transparent. The mentioned taxonomy was developed by exploring major types of GENAI models based on their mechanisms. They were then categorized according to AI models. Finally, post-hoc expandability techniques were provided for these GENAI models. Each step of the methodology is meticulously created to provide a comprehensive understanding of the intersection between generative AI and construction, elucidating the theoretical underpinnings and practical implications for future research and applications.

Artificial Intelligence

Over the past decade, the construction sector has lagged in adopting transformative AI advancements that have revolutionized other industries. Notably driven by machine learning and its specialized subset, deep learning, these breakthroughs harness historical data to predict patterns, enabling automated generative design and analysis processes. Deep learning techniques, exemplified in Baduge et al. (2022), facilitate automated structural evaluation and design, emphasizing prestressed components. AI in construction promises generative and optimized layouts, safety risk prediction and mitigation, energy cost reductions, accelerated project timelines, enhanced financial returns, and sustainable building practices. The replicative capabilities of AI address feasibility and scalability challenges posed by big data in the construction sector. Despite being in an experimental stage, the rapid evolution of AI applications in construction, supported by expanding research and consistently impressive results, anticipates widespread integration and commercial viability in the near future (Love et al., 2023; Angelov et al., 2021).

Generative Design and Generative AI

The architectural design process is conventionally divided into three integral phases: the initial conceptual or scheme design, the detailed preliminary design incorporating optimization, and the creation of construction drawings. The conceptual phase holds paramount significance as it molds the ultimate design and heavily relies on the designer's expertise. Addressing prevalent issues in structural design, such as inefficiencies, data underutilization, and knowledge transfer challenges, has prompted a growing emphasis on smart design strategies. Leveraging historical design data, architectural concepts, and various forms of knowledge, the evolving approach employs generative AI to efficiently produce new designs (Kanyilmaz et al., 2022). The GD process comprises three components: a design schema, creating variations, and selecting desirable outcomes (Krish, 2011).

Generative design, rooted in facilitating innovation, utilizes algorithmic software driven by parameters set by designers, including materials, geometric shapes, and loads. The incorporation of artificial intelligence into generative design processes utilizes metaheuristic search algorithms, such as genetic algorithms, to explore and identify efficient solutions within predefined design frameworks. This transformative approach comprises three core elements: a generative geometry model, criteria defining design objectives, and a metaheuristic search algorithm. Generative AI has emerged as a pivotal technological development, prominently featured in intelligent design to overcome inefficiencies in the structural design industry (Avital, 2007; Junk and Burkart, 2021; Liao et al., 2024). This article delves into data feature representation, intelligent structural design creation, and robust design outcome assessment within the realm of generative AI for architectural design.

Singh's explorations in 2012 of generative design techniques, detailed in Table 1, encompasses SG, CA, GA, LS, and SI, considering their technical, design, and system development characteristics. Integrating these computational systems poses challenges due to the necessity for a common language across diverse generative design (GD) techniques. Singh envisions an interactive expert system, placing the designer at the core of the GD process. Meanwhile, Krish (2011) proposes generative design methods (see Figure 1 and outlined at the top of Table 1). Contemporary research emphasizes adapting generative AI models, employing deep learning methods like CNNs, GNNs, and RNN/LSTM for domain-specific problem-solving, as elucidated by advanced algorithms in the last section of the table (Liao et.al, 2024). Generative AI holds the potential to revolutionize data management in architecture, engineering, and construction (Ghimire et al., 2023). However, its transformative impact in the construction industry is hindered by issues, including a gap between research and industry, hesitancy due to interpretability, feasibility, reliability concerns, and ethical considerations (Arrieta et al., 2020).

Explainable Artificial Intelligence

Explainable artificial intelligence (XAI) is a collection of methodologies designed to enable human users to understand and trust the outcomes of artificial intelligence systems. The objective of any XAI method is to make the decision-making of AI models transparent and interpretable. Anand et al. (2020) have persuasively argued that AI algorithms often resemble inscrutable "black boxes" due to their intricate, nonlinear structures that are hard to elucidate, even for their creators. The inability to fully understand machine learning and deep learning models entails risks when relying on their unexplained outputs. XAI has thus been developed to help users grasp the rationale behind the specific outputs of AI systems. The diminished explainability of AI models has led Gerling et al. (2021) to assert that the inability to elucidate algorithms means we cannot contest, validate, enhance, or derive knowledge from them. Therefore, generating explanations that clarify the functioning of DL and ML models, as well as the basis for their decisions or predictions, is crucial for fostering trust in these technologies. Arrieta et al. (2020) have characterized XAI to provide insights or justifications that render the operations of a model transparent and easily comprehensible. While a consensus on the definition remains elusive, it is widely accepted that XAI systems ought to articulate their capabilities, recount their past actions, describe their current activities, predict future outcomes, and disclose the pertinent data upon which they operate. To achieve these ends, XAI addresses concerns related to interpretability and transparency.

	Two neural networks, a generator, and a discriminator, compete with each other to generate realistic data.		Encodes data into a latent space and then decodes it back into the original space.		Generate data one step at a time, using the previously generated data as input.	Start with a noisy image and gradually refine it to a realistic image.	Transform data from one distribution to another using a series of invertible functions.

XAI is a complex concept encompassing intrinsic or post hoc nature, local or global scope, and model-specific or model-agnostic applicability (see Figure 2).

Defining XAI definitively demonstrates challenging due to context-dependent interpretability, varying across domains, as illustrated in Figures 2 and 3. Although these terms are frequently used interchangeably, they may convey distinct nuances in various settings. To enhance clarity, the distinctions and commonalities among terminologies frequently employed within the realms of ethical AI and XAI are elucidated in this section:

- Understandability refers to a model's inherent quality that enables a human to grasp its functionality—how the model operates—without necessitating an exposition of its internal architecture or the algorithmic processes it utilizes to manage data internally.

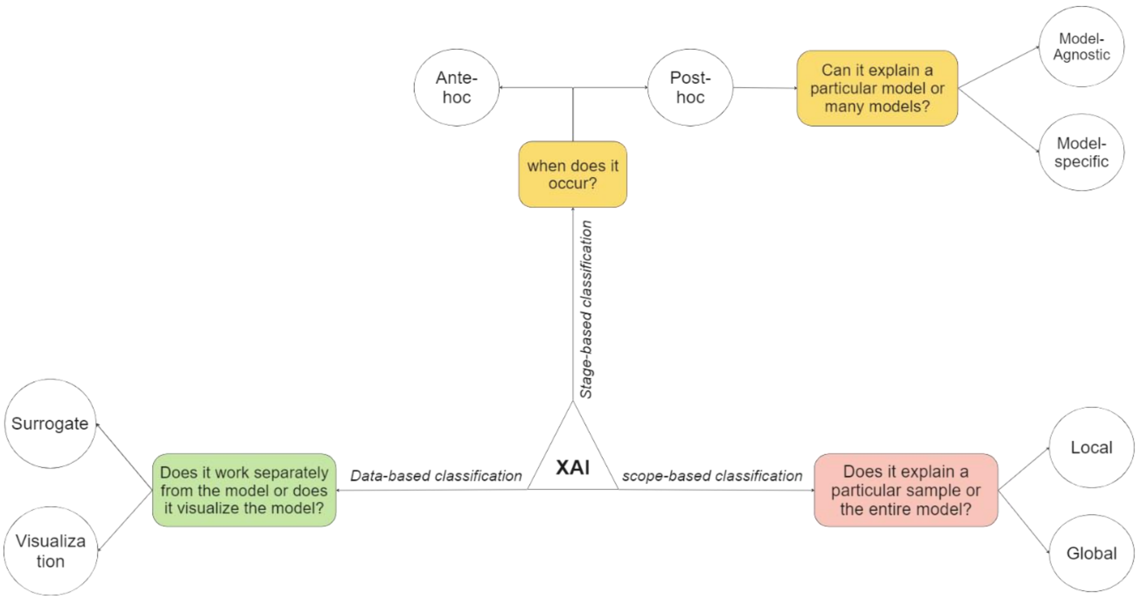

Figure 2. Preliminary stages in application of XAI (Source: Authors).

- Comprehensibility, when applied to machine learning models, pertains to the capacity of a learning algorithm to present its acquired knowledge in a manner that is intelligible to humans.
- Interpretability is described as the facility to convey significance in terms accessible and clear to a human observer.
- Explainability is crucial, acting as a bridge between humans and decision-making entities. It involves post-hoc methods to make opaque models intelligible. In this document, we prioritize explainability as the primary design goal, recognizing its comprehensive importance.
- Model transparency hinges on inherent comprehensibility, categorized into simulation models (step-by-step emulation), decomposable models (examining components and interconnections), and algorithmically transparent models (visible internal logic and decision-making processes).

Explainable generative AI design in construction

As AI becomes increasingly integrated into applications that directly impact humans and as the ramifications of algorithmic decisions grow, the construction industry must broaden its focus beyond merely the predictive accuracy of ML and DL models to include their explainability (Love et al., 2023). Generative AI has the potential to transform data management in architecture, engineering, and construction, offering efficient processing of unstructured data through large language models (LLMs). A few examples can be found in Figure 4. Generative AI fosters seamless information exchange between tangible and digital realms in construction projects, enhancing comprehension and decision-making in project management by accessing previously inaccessible unstructured data (Ghimire et al., 2023). As the authors mention in their article, the potential of Gen AI in construction is:

1. To extract project information from construction documents such as dimensions, materials used, responsible person, point of contact, etc.
2. To generate new documents. Examples- proposals, reports, etc.
3. To classify & cluster documents based on project types, internal departments, sub-contractors, project phases, document types, materials, supply chain, etc.
4. Generating code to automate tasks.
5. Optimizing cost estimation workflow.
6. To help quality control by comparing completed tasks to project specifications to identify defects and deviations.
7. To generate an optimal schedule path.

Construction organizations have been reluctant to adopt artificial intelligence (AI) systems, not because of unwillingness, but due to the lack of explainability of autonomous decisions and actions made by AI, which undermines confidence and trust (Love et al., 2023). XAI offers significant benefits for construction, including reduced model bias, enhanced trust, actionable insights, and risk reduction. XAI elucidates the rationale behind AI decisions and capabilities (Love et al., 2023). Explanations can facilitate collaborative co-design among stakeholders, empowering them to make informed decisions about system use and appropriate timing for performance assessments (Khosravi et al., 2022). Consequently, evaluating XAI requires comprehending diverse socio-political environments of stakeholders using an interpretive approach that enables deeper understanding and generates motivation and commitment (Love et al., 2022).

As it is depicted in Figure 5, there are various approaches that can be selected for implementing XAI solutions tailored to generative design algorithms, contingent upon the differing characteristics of the models and their associated computational processes. In the following section, different types of XAI approaches that can be used to make generative design algorithms explainable are presented.

- **Local Explanations:** It focusses on explaining individual predictions or decisions made by the AI model. In the context of generative design, this could involve explaining why certain design choices were made for a specific instance. Techniques such as Local Interpretable Model-agnostic Explanations (LIME) or SHapley Additive exPlanations (SHAP) can be used to provide these local insights.
- **Global Explanations:** Unlike local explanations, global explanations aim to provide an understanding of the model's overall behavior. For generative design algorithms, this could involve explaining the general principles or rules the model uses to generate designs across different scenarios.
- **Feature Attribution Methods**: These methods explain the output of a model by attributing the prediction to the input features. For generative design, this could mean identifying which features of the input data are most influential in the design generated by the AI.
- **Visual Explanations:** Visualization techniques can be used to illustrate how the generative model is transforming input data into a design. This could include visualizing the activation of different layers in a neural network or showing intermediate steps in the design process.
- **Example-Based Explanations:** Providing examples of similar designs or design decisions made by the AI can help users understand the rationale behind the generated designs. This could include showing nearest neighbors or variations of the design that were considered by the algorithm.
- **Feature Attribution Methods**: These methods explain the output of a model by attributing the prediction to the input features. For generative design, this could mean identifying which features of the input data are most influential in the design generated by the AI.
- **Visual Explanations:** Visualization techniques can be used to illustrate how the generative model is transforming input data into a design. This could include visualizing the activation of different layers in a neural network or showing intermediate steps in the design process.
- **Example-Based Explanations:** Providing examples of similar designs or design decisions made by the AI can help users understand the rationale behind the generated designs. This could include showing nearest neighbors or variations of the design that were considered by the algorithm.
- **Counterfactual Explanations:** Such explanations provide insights into how the input could be changed to achieve a different outcome. In generative design, counterfactuals can help users understand how altering certain design parameters could lead to different design results.

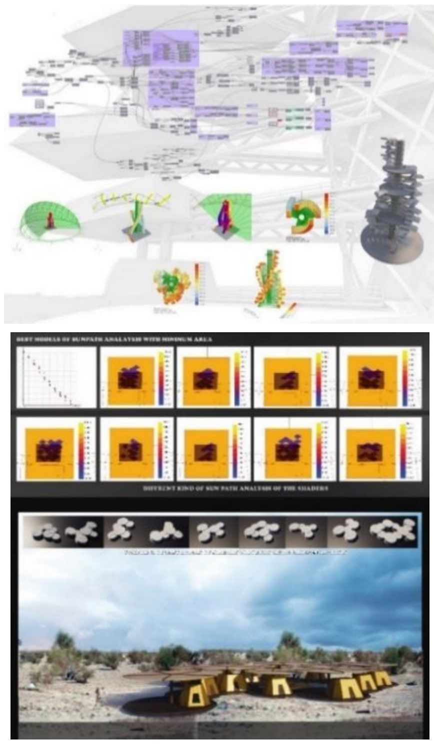

Figure 4: Examples of generative design process in the initial conceptual or scheme design (Source: Authors).

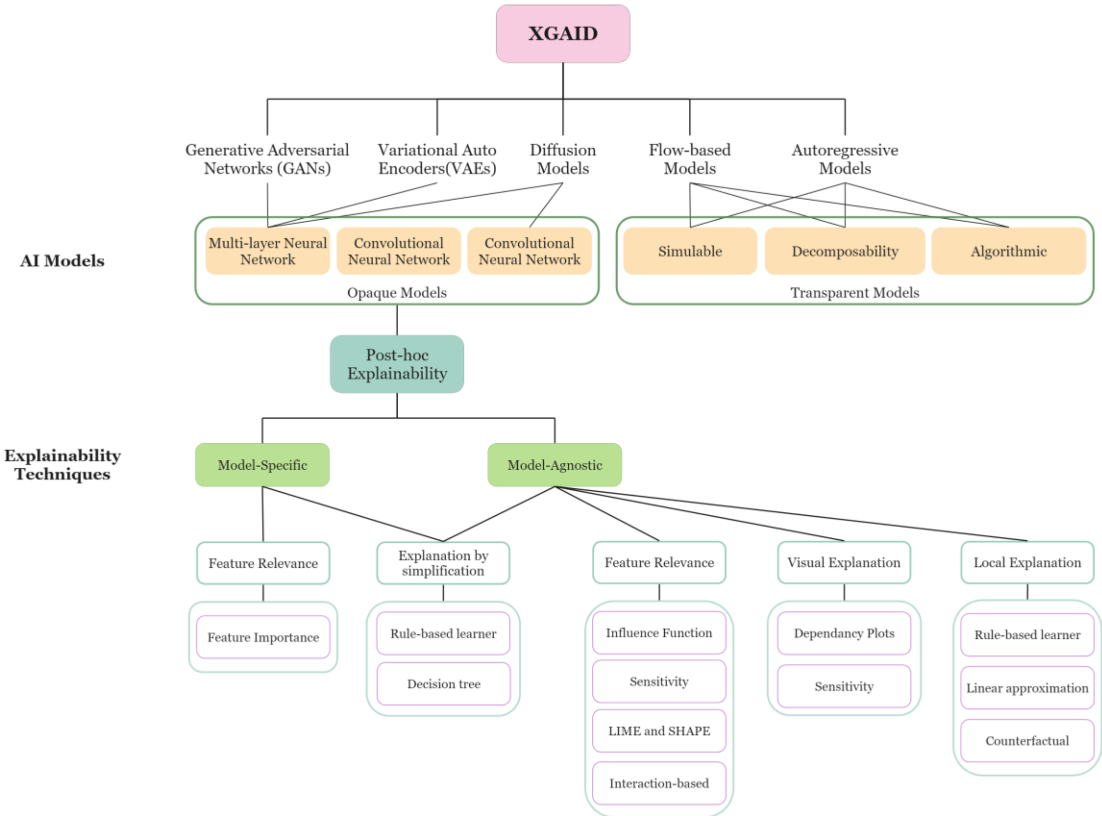

Figure 2: Proposed explainable generative AI design taxonomy (Source: Authors).

- **Interactive Explanations:** These tools allow users to explore and manipulate the AI model's inputs and observe the changes in the outputs. This hands-on approach can be particularly effective in helping users understand the generative process and the impact of their design choices.
- **Model Simplification:** Simplifying complex models into more interpretable forms can also serve as an XAI approach. For instance, a complex generative design model could be approximated by a simpler model that captures the main trends and patterns, making it easier to understand and explain.
- **Causal Inference:** Causal inference methods aim to understand the cause-and-effect relationships within the data that the AI model uses. In generative design, this could involve identifying which elements of the design are causing certain features or outcomes in the generated product. Techniques like causal diagrams or intervention analysis can help in providing these insights.
- **Process Tracing:** This approach involves tracing the decision-making process of the AI model step by step. For generative design, this could mean detailing the sequence of operations the model performs to arrive at a particular design, which can help users understand the generative process in a more granular way.
- **Natural Language Explanations:** Some XAI systems can generate textual descriptions that explain the AI's decisions in human-readable form. For generative design, the AI could provide annotations or descriptions of why it made certain design choices, which can be more intuitive for users without technical expertise.
- **Sensitivity Analysis:** This involves studying how changes in the input affect the output of the AI model. In generative design, sensitivity analysis can help determine which design parameters are most influential and how variations in these parameters can alter the final design.
- **Uncertainty Quantification:** Providing information about the uncertainty and confidence of the AI's decisions can be a form of explanation. In generative design, this could mean indicating the level of certainty the AI has about each aspect of the design it generates, which can help users make informed decisions about whether to accept, modify, or reject the AI's suggestions.
- **Rule Extraction:** Some XAI approaches aim to extract human-understandable rules from complex models. For generative design, this could involve distilling the AI's decision-making

process into a set of rules or guidelines that explain how different design outcomes are achieved.

Also, there is the option to make hybrid approaches by including more than one XAI algorithm at once. Hybrid approaches aim to leverage the strengths of both ante-hoc and post-hoc explainability. For example, a model may be trained with regularization techniques that promote sparsity, making it easier to identify which features are most influential, while still allowing for post-hoc analysis to explain individual predictions. Another hybrid strategy might involve training a complex model to achieve high performance and then using a simpler, inherently interpretable model to approximate the complex model's behavior in a way that is understandable to humans (Sun et al. 2022, Amershi et al.2014, Ross et al. 2021).

Discussion

While AI has been implemented across various industries, those systems cannot yet fully replace construction managers, engineers, and clients in building projects due to concerns around replacing human judgment with computational processes. However, this paper proposes a framework integrating explainable AI techniques into generative design workflows, which could improve process clarity for users. By increasing trust in AI through explainable methods, these systems may gain wider acceptance in construction. However, within current literature, evaluation frameworks for explainable AI remain underdeveloped, as the notion of explainability lacks consensus.

The proposed taxonomy aims to provide researchers and practitioners with a simple yet effective way of evaluating the XAI approaches available for the GD AI algorithm used in a systematic manner. The selection of the XAI algorithm from an effective manner has not yet been evaluated and remains a work in progress.

Nonetheless, basic tenets like interpretability and transparency are agreed upon. Although explainability has received limited focus in AI research on construction generative design, future work could employ existing post-hoc explanation methods to elucidate the functioning of machine and deep learning models. Qualitative approaches may also evaluate explanations as a precursor to developing quantifiable metrics. Moreover, while this paper presented a broad taxonomy for most generative AI models in design, more specific taxonomies for all model types require investigation. The relationship between individual mechanisms and their combination can be separately considered and presented. Additionally, balancing model performance and explainability poses challenges. More complex models like deep neural networks can generate higher quality outputs yet tend to be less interpretable, whereas simpler models may be more explainable but have limitations in producing novel optimized designs. Hence, hybrid approaches leveraging both complex and simple models warrant exploration.

Conclusion

This paper proposes a taxonomy for the integration of explainable AI (XAI) into generative design, with the aim of increasing user trust and paving the way for future AI applications in the construction industry. XAI enables transparency and accountability, building trust in AI-enabled construction solutions. The adoption of XAI is necessary to maintain a competitive edge and comply with evolving regulatory mandates. By merging XAI with generative algorithms, design quality, efficiency, and stakeholder satisfaction can be enhanced. However, realizing XAI's full potential requires investment in professional training and research refining XAI for construction-specific deployment. In conclusion, explainable AI has the potential to revolutionize construction design through human-centered generative practices and a unified commitment to its progression.

TOWARDS A SOLUTION FOR THE PRE-FAILURE CONCRETE ELEMENT CRACK DETECTION PROBLEM

Karolina Tomaszkiewicz[1], Tomasz Owerko[1]
[1]AGH University of Krakow, Poland

Abstract

Crack detection in concrete bridge elements is critical to the bridge's durability and safety. The ability to link cracks with the type of damaged element, location, and the moment of occurrence is critical for understanding the structure's behaviour. While the detection of cracks in concrete representing the failure condition is currently a relatively straightforward task, the identification of narrow cracks representing the pre-failure state has not yet received a satisfactory solution. This paper discusses a solution for segmenting structural elements on images and segmenting cracks using a deep learning network trained on a prepared dataset of pre-failure concrete cracks.

Introduction

The occurrence of cracks in reinforced concrete structures is a natural phenomenon, which in many cases cannot be avoided. In order to be able to assess whether the occurrence of cracks may affect the durability of the structure and pose a risk to its safety, it is necessary to determine the probable cause of the damage, based on factors such as the nature of the element's work, the place where the damage occurred or the time at which the damage occurred (e.g. after performing load tests). At the same time, the formation of cracks can be caused by the effects of both mechanical and environmental factors, as well as being the result of design or construction mistakes. It should also be noted that according to Eurocode 2 (CEN, 2004) the crack limit value (i.e. the value above which the serviceability limit state of the structure is exceeded) is a very small value and is 0.3mm.

For this reason, during the engineer's site inspection, these cracks may be difficult to detect by human eye, particularly in areas that are difficult to access such as pylons, spans over rivers and the inside of box girders. At the same time, the engineer inspecting the technical condition of the structure by reviewing individual elements, assessing the size of the damage, and documenting with photographs is the person who is responsible for assessing the impact of the damage on the structure's safety, and who decides on the necessary repair works or taking the structure out of service. The inspection process is labour-intensive, time-consuming and, in particular, is subject to the engineer's subjective opinion and experience. It has been estimated that approx. 50% of condition assessments are incorrect or vary depending on the engineer who performs the inspection (Hüthwohl et al., 2019).

This paper presents a solution based on machine learning algorithms that can support the engineer's work and condition assessment of structures. This solution allows for the detection of bridge structure elements on images and then the detection of cracks for a particular structure element in relation to the location of the damage. Particularly, by training a neural network based on a dataset of cracks representing the pre-failure state of the structure, the presented solution can be used to detect damage at an early stage of its occurrence. Detecting the cracks of reinforced concrete or asphalt structures representing the failure state is a relatively straightforward task in the current state of the art (Ali et al., 2022; Li et al., 2022; Nguyen et al., 2023), but identifying the pre-failure state indications in the form of very narrow cracks has not yet received a satisfactory solution. By diagnosing the occurrence of a crack at the pre-failure stage and linking it to a possible cause based on where the damage occurred, it is possible to take the necessary repair steps (e.g. protecting the damage), to monitor the development of the damage and, consequently, to extend the service life of the structure.

The first part of this paper discusses the causes of cracks in reinforced concrete elements of bridges and indicates for which elements a given cracking caused by a given factor is characteristic. The second part discusses the authors' dataset "NCCD-PF - A pre-failure narrow concrete cracks dataset for engineering structures damage classification and semantic segmentation" (Tomaszkiewicz & Owerko, 2023b). The segmentation of concrete elements of a bridge structure for which cracks are detected is presented in the third part. The fourth part, in turn, presents the solution of a deep learning algorithm trained based on the discussed dataset, for the identified structural elements.

The problem of cracks in reinforced concrete elements

The bridge condition inspection procedure varies from one country to another. The inspection procedure varies in terms of the frequency of inspections, the types of elements that need to be checked in a particular type of inspection, the value of the condition ratings of the elements. Regardless, the procedure for conducting the inspection itself is because an engineer performs an on-site inspection. In the case of damage, it is the engineer's responsibility to note this fact in the inspection protocol and to make documentation of the damage. At this stage, the engineer is required to decide whether the damage represents a risk to the bridge, whether additional expert work should be carried out and the urgency to do these works. This stage when the engineer decides whether the damage represents a risk to the structure is supported by the approach presented in this paper, in relation to concrete cracking.

Cracking in reinforced concrete structures is a natural phenomenon, which in many cases cannot be avoided. In order to be able to assess whether the occurrence of cracking may affect the durability of the structure and pose a risk to its safety, it is necessary to determine the probable cause of the damage, based on factors such as the nature of the given structural element's work, the place where the damage occurred or the time at which the damage appeared (e.g. after carrying out test loads on bridges).

Among the most characteristic cracks that occur in reinforced concrete elements, we can point out (Tomaszkiewicz & Owerko, 2023a):

- Cracks caused by the compression of a reinforced concrete element - in particular abutments, pillars
- Cracks caused by the excessive bending moment stress - especially in girders, in zones of extreme bending moment
- Cracks caused by nonuniform settlement of supports in particular abutments, pillars, foundations
- Cracks due to plastic shrinkage - especially observed for bridge slabs, pedestrian paths, concrete pavements
- Cracks in prestressed elements caused by corrosion of tendons, corrosion of tendon anchorages - characteristic for girders or anchorages of cable elements suspending the superstructure.

A particular type of cracking occurring in bridge structural elements is that of massive elements such as foundation slabs, abutments, pillars and pylons. The massiveness of a structural element can be defined as the ratio of the surface area of the element to its volume. In the process of cement hydration during concrete setting, the ratio of the surface area (i.e. the area through which the heat of hydration is removed) to the volume in which it is emitted is small. These cracks already appear during the construction phase, i.e. when the concrete strength is significantly lower than the design strength and when the bridge structure is not yet operating under full-service load. In addition, under further loading, cracks may propagate through the entire thickness of the concrete, resulting in a loss of structure monolithicity and a change in its static scheme.

The link between the type of structural element, the location of the damage and the causes of the damage will be discussed using the example of an abutment of a bridge structure. As a result of the cement hydration process, the temperature inside a concreted abutment rises to a maximum and then decreases to equalise with the ambient temperature. This results in tensile stresses that exceed the strength of the 'young' concrete. At the same time, the development of shrinkage phenomena occurs, resulting in cracking of the element. During the heating phase, the central part of the element heats up to a higher temperature than its edge, which causes the edge zones to be stretched. In the cooling phase, the central part of the element shrinks to a higher temperature than the edge, which causes stretching of the central zone of the element. Abutment walls are the elements in which the deformation of the lower edge is limited by external constraints. Abutment walls are concreted after the foundation has hardened and cooled, hence the curing of the wall takes place when the bottom of the wall is restrained in the foundation and there is no possibility of deformation. Therefore, thermal-shrinkage cracks of abutments are vertical cracks that begin above the abutment wall-foundation interface and disappear at the top of the abutment wall.

Description of the dataset for pre-failure cracks in concrete elements

The dataset developed by the authors "NCCD-PF - A pre-failure narrow concrete cracks dataset for engineering structures damage classification and semantic segmentation" (Tomaszkiewicz & Owerko, 2023b) has been made available as an open dataset and described in detail in the publication (Tomaszkiewicz & Owerko, 2023a). This dataset is dedicated to the problems of classification and segmentation of reinforced concrete element cracks. One of the dataset's characteristics is that it only represents those cracks which do not exceed a width of 0.3mm. This value is defined in EC 1992-1-1 (CEN, 2004) as the limit value of a crack with respect to typical construction methods for engineering elements and the conditions under which they operate. The crack detection using the algorithm trained on the presented dataset therefore allows the detection of cracks at the pre-failure stage. In addition, the dataset is characterised by the presence of a complex concrete surface finish (Figure 1), which can significantly influence to the results of the machine learning algorithms. The dataset's characteristic concrete surface complexity is shown in Figure 2.

The images that compose the dataset have been differentiated by:

- The type of element on which the cracks occurred (e.g. abutment, pillar, concrete barrier, tunnel wall)
- The cause of the cracks (e.g. thermal and shrinkage stresses in young concrete)
- Stage in the life cycle of the structure at which the image was obtained (from the construction stage to the operational stage)
- Quality of the reinforced concrete element construction, its maintenance and conservation.

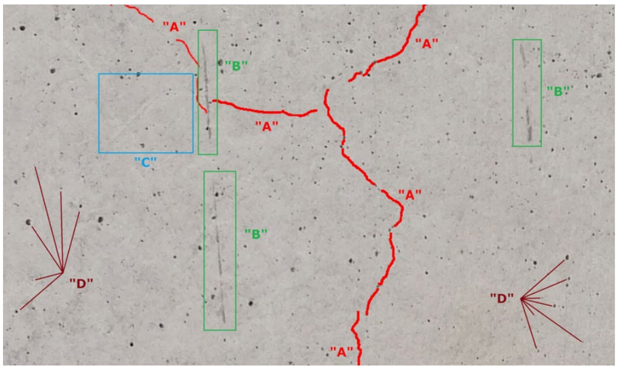

Figure 1: Example of concrete surface texture complexity. Marked as: "A" - cracks, "B" - dirts, "C" - mechanical damage, "D" – potholes (*Tomaszkiewicz & Owerko, 2023a*)

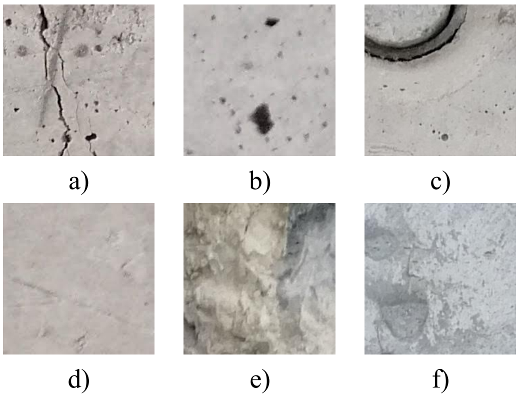

Figure 2: Example of concrete surface texture complexity, where a) dirt, b) bugholes, c) formwork marks, d) mechanical damage e) background obstructions f) troweling marks (Tomaszkiewicz & Owerko, 2023b)

The method of data acquisition for the dataset construction was chosen in such a way that the data acquired corresponds to the conditions under which bridge inspections are conducted. The images were obtained from cameras, without prior conditioning.

The dataset development started with the preparation of segmentation masks. An example of an image and its corresponding segmentation mask is shown in Figure 3 and 4. The images prepared in this way were segmented into sub-images of 224x224 pixels. On their basis, a classification dataset was created, examples of which are shown in Figure 5 (images of cracked concrete) and Figure 6 (images of uncracked concrete), respectively. The size of the dataset is shown in Table 1.

Crack location based on segmentation of the structural element on images

To preserve the link between the bridge structure element and the damage, it is possible by segmenting an image of the single structural elements of the bridge structure and then providing data about a specific element as input information for a solution based on deep machine learning networks. For this purpose, the authors adapted the SegmentAnything algorithm (Kirillov et al., 2023) for iterative segmentation of bridge structure elements. Images identified as a structural element of a specified class are then segmented into sub-images and entered into a neural network. As a result, once the concrete surface cracks have been segmented using a deep learning algorithm, it is possible to link this damage to the element on which it occurred. Using this approach, a crack image of a given structural element is obtained, with the identification of those cracks that may pose a risk to the structural element and should be monitored and those that can be considered as neutral phenomena. An example of segmentation of reinforced concrete bridge elements is shown in Figure 7.

Figure 7: Results of bridge element segmentation

Crack detection solution using deep machine learning

Previous authors' experience (Tomaszkiewicz & Owerko, 2022) has shown that using networks trained on datasets for cracks with larger widths and fine-tuning them is not a proper solution for obtaining correct segmentation of cracks with widths below 0.3mm. The authors have developed a dedicated solution for pre-failure crack segmentation. The computer implementation was done using the PyTorch library.This solution used a modified and adapted UNet architecture originally proposed by (Weng & Zhu, 2015). The individual components of the network such as activation layers, convolution blocks etc. were implemented manually, the networks available in the PyTorch library were not used.

The network training process was based on a subset of 791 images from the presented dataset. The image size adopted for analysis was 224x224 pixels, which is also the original size of the images in the developed dedicated dataset. The images were randomly divided into a training and validation dataset in a ratio of 80:20. The dataset was divided into a batch size of 16 and trained for 125 epochs.

The results obtained, presented in Table 2, showed a high match between the network's prediction and the segmentation masks derived from the dataset. The information extracted in this way is sufficient information to be included on the image of the whole structural element and be used to assess its technical condition.

Limitations and future work

The presented deep learning solution covers one architecture that is effective for this problem but is not a most recent type of architecture (such as transformers). Furthermore, a problem that exists worldwide is that the amount of publicly available datasets related to the detection of different types of objects is severely limited. Data is not collected in a structured way, regarding FAIR Principles (Wilkinson et al., 2016).

Further research should be conducted in such a way that good quality datasets for deep learning algorithms can be built partly automatically. The procedures for performing bridge inspections should be developed or adapted in such a way that they meet the requirements for conducting inspections, but also allow the collecting of structured data that can be used for training deep learning algorithms. An important direction is also to conduct tests on different types of concrete mixes, keeping in mind the different potential causes of cracking. It may be helpful here to link the computational model to the location of damage in the structure, e.g. as a result of excessive loads). Such data can provide support for research related to the application of recent deep learning architectures based on multi-dimensional data as a source of knowledge (including consideration of IFC class, observation history from IoT sensors).

Abstract

This paper introduces a method for diagnosing facility management (FM) work systems to improve situation awareness (SA). Identifying SA as a critical factor of success in FM, we propose a method to diagnose FM work systems, integrating multiple methods and offering a comprehensive sociotechnical systems perspective. The findings show the internal validity of the method, its application, and the identification of SA-impacting factors in FM work systems. Implications include continuous improvement and a proactive approach to addressing SA challenges in the FM work systems.

Introduction

The Facilities Management (FM) industry faces mounting pressure to align with sustainable development goals, exacerbated by the escalating complexity of digital transformation in the built environment (Nielsen et al., 2016; Okoro, 2023). This complexity necessitates a shift from traditional social systems to sociotechnical systems within FM work systems, wherein technical and social components are integral to decision-making processes (Yalcinkaya and Singh, 2014). However, this transformation has introduced challenges, particularly in maintaining up-to-date and comprehensive situation awareness (SA), which is crucial for informed decision-making.

SA, a critical factor in various domains such as nuclear power plants, healthcare, and aviation, remains relatively underexplored in the FM domain despite its evident importance (Gheisari and Irizarry, 2011; Gheisari, 2013; Akinci, 2014). Existing literature suggests two dominant and distinctive views on situation awareness; one defines SA as a cognitive product of individuals, and the other views it as an emergent property from interactions in a system. Acknowledging the multifaceted nature of SA, there is a need to adopt a sociotechnical systems perspective, where both views are accounted for, considering FM actors, FM technologies, and their interdependencies in achieving and maintaining SA. Evidence suggests that many individual and system-level factors interdependently influence SA in sociotechnical systems (Lau and Boring, 2016; Kurapati, 2017).

Improving FM work systems necessitates diagnosing the work systems and addressing the problems to support situation awareness. In this direction, the research community has put significant efforts into assessing the situation awareness of individuals and groups, taking a descriptive approach where only the social aspect of the work system is considered (Gawron, 2019; Alhaider, 2022). We argue that a normative approach with a sociotechnical systems perspective is required to effectively guide the interventions to address the SA-related issues in complex work systems. Moreover, existing methods expect a certain level of expertise in the SA domain (Salmon et al., 2006), presenting a barrier for the practitioners in the FM industry to utilize these methods and take an interest in them.

This research aims to bridge these gaps by establishing a problem-solving approach to address situation awareness-related issues in the FM sociotechnical (work) systems. In this regard, we propose a method to diagnose FM work systems to identify underlying patterns of SA-impacting factors.

By integrating insights from individual and system-level SA processes, this approach seeks to enhance SA within FM work systems, ultimately improving facility performance and supporting informed decision-making.

This work presents empirical findings from applying our proposed method and discusses implications for research and practice in the FM industry.

Literature review

This literature review delves into the evolution of contemporary Facilities Management (FM) work systems, understanding the shift from social systems to complex sociotechnical systems. Then, we inspect the challenges this transformation poses for achieving and maintaining high situation awareness (SA) levels among FM actors. Additionally, we explore strategies for diagnosing FM work systems to effectively address SA challenges, thereby augmenting informed decision-making and overall system performance.

Contemporary FM Work Systems and Rising Complexity

As the FM domain approaches contributing to sustainability, it is expected to play a strategic role beyond achieving efficiencies in operations and maintenance of the buildings and infrastructure (Collins and Junghans, 2015). In this broader context, FM can be considered "an integrated approach to operating, maintaining, improving and adapting the buildings and infrastructure of an organization to create an environment that strongly supports the primary objectives of that organization" (Barrett and Baldry, 2003). Towards addressing the sustainability challenges, i.e., achieving operational efficiencies, gaining competitive advantages, maintaining stakeholders' satisfaction, adhering to regulatory compliances and standards, and achieving resilience and sustainability of the built environment, the FM domain is going through a technological transition where advanced technologies like BIM, IoT, AI-ML, AR-VR, Building Automated Systems, ICT-based tools, Digital Twin-CPS, Blockchain/ DLT and emerging technologies, are becoming integral parts of FM work systems (Araszkiewicz, 2017; Yalcinkaya and Singh, 2019; Lee et al., 2021; Elyasi et al., 2023). Figure 1 explains FM as a sociotechnical (work) system adopting the framework proposed by (Brandt and Cernetic, 1998) where complex networks of social and technical systems (i.e. large teams of technicians, managers at different organizational levels, third-party companies and various technical systems associated with FM process and smart infrastructure) need to work collaboratively for effective management of the built environment. The attempts to bring sophistication to the built infrastructure and the intricacy of the FM work systems have posed challenges to FM actors in achieving and maintaining situation awareness, leading to poor decision-making and negative outcomes for facilities while increasing complexity.

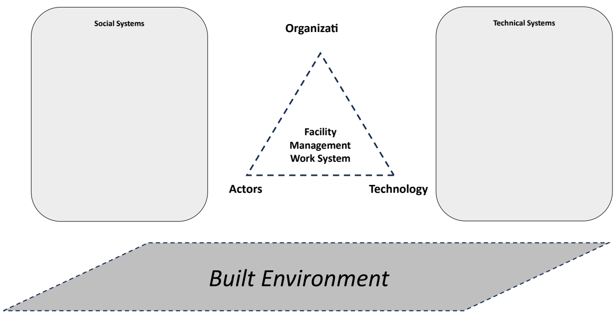

Figure 1:Facility Management as a sociotechnical system.

To further emphasize our claim, we analyze the dimensions of complexity suggested by (Vicente, 1999) in Table 1 to characterize FM work systems as a complex sociotechnical system.

Table 1: Characterizing FM work systems as a complex sociotechnical system with dimensions of complexity by (Vicente, 1999)

Dimensions of complexity	Definitions	Application to FM
Large problem space	Many different elements and forces	Many multidisciplinary functions shall be met by integrating people, processes, technology and places by effectively understanding the needs of the organizations and their peoples.
Social System	Composed of many actors who must work together	Inhouse social system + Outsourced social system + Customers + Owners
Heterogeneous perspectives	Actors with different backgrounds and disciplines	Operational and strategic perspectives, different disciplines, and conflicts of interests
Distributed system	Sub-systems located in different places	Different building systems at different locations, remote operations, teams at different locations, Cloud Computing
Dynamic system	Effects of actions, changes with times	Complex and dynamic built environment
Hazards	The high degree of potential hazards	Failures of critical infrastructures
Coupling	Highly coupled interactive subsystems	Tight coupling with organization and loose coupling between technical systems
Automation	Highly automated systems	Building Automated Systems, AI in FM
Uncertainty	Uncertainty in data available to actors	Rely on first responders, manual collection of data, and fragmented subsystems.
Mediated interactions	Systems not observable directly by actors	CAFM, Observable by Digital Interfaces
Disturbances	Actors dealing with unanticipated events	Unpredictable behaviours and activities of occupants, facility failures

Situation Awareness in FM Work Systems

The primary function of FM work system is to ensure the functionality, safety, comfort, efficiency and sustainability of the built environment (IFMA, 2024). To achieve this, the FM work system, i.e. the actors and FM technologies, continuously interacts with the facilities, its occupants and the core organization to get required situation awareness, which supports decision-making and performance of actions to deliver the agreed services successfully (see Figure 2). SA enables teams and individuals to keep an accurate mental picture of their environment and helps them anticipate changes and make well-informed decisions in complex and dynamic settings (Sorensen and Stanton, 2016). In other words, an adequate level of SA for FM actors will mean that they are aware of what has happened (Perception), what is happening (Comprehension), and what could happen (Projection) at any point, which is fundamental to making well-informed decisions. For instance, in a large office building with a centralized HVAC system, FM actors continuously monitor temperature, airflow, and energy usage to be aware of what has happened and what is happening. If they detect a sudden temperature increase in a zone, they anticipate a potential malfunction or high occupancy. This awareness of the current situation enables them to make informed decisions and take proactive actions to maintain comfort and optimize resource usage.

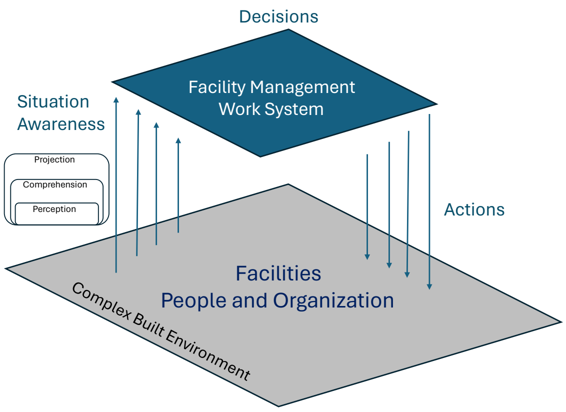

Figure 2 : Situation Awareness in Facility Management Work Systems

However, contemporary FM work systems can be characterized as complex sociotechnical systems where achieving and maintaining SA is challenged by an intricate interplay of many SA-impacting factors (Salmon, 2008; Boy, 2013; Lau and Boring, 2016). This necessitates a case for a sociotechnical systems approach to study SA in FM work systems.

The most influential work of situation awareness defines it as the perception and understanding of elements within an environment, coupled with the comprehension of their meaning and the projection of their status in the near future (Endsley, 1995). Apart from this, (Sarter and Woods, 1991) describe situation awareness as built on working memory and mental models: "Situation awareness is based on the integration of knowledge resulting from recurrent situation assessments". Additionally, (Tenney et al., 1992; Smith and Hancock, 1995)'s models are some of the most cited situation awareness models. Most of these theoretical constructs of situation awareness take an individualist view where situation awareness is considered a product of the active situation assessment process. This view highlights task-related, individual, and environmental factors impacting SA. Stanton presents another dominant view for situation awareness with a systems perspective, i.e. Distributed Situation Awareness (DSA). DSA expands on the idea of SA to include human and technological agents that work collaboratively, and SA emerges from SA transactions amongst them (Stanton et al., 2006; Salmon, 2008). This viewpoint strongly emphasizes team members' shared mental models, communication, and coordination to preserve a thorough grasp of the operating environment. Apart from the Stanton model on situation awareness, Endsley's and Jones's model on situation awareness and Artman and Garbis's distributed cognition model are some of the models that account for situation awareness from a team perspective (Artman and Garbis, 1998; Endsley and Jones, 2001). The reviewed literature suggests five dimensions for factors impacting SA in a sociotechnical system, i.e. individual, team, task/domain, technological, and environmental. Table 2 presents factors identified in literature impacting situation awareness in the sociotechnical system.

Table 2: List of factors impacting SA from the literature.

Categories	Factors Impacting SA
Individuals	Attention Tunneling, Errant mental models, Requisite Memory Trap, Out-of-the-loop syndrome, Goals and Expectations, Experience and training, Stress and fatigue, Training, Cognitive Load
Technology	Complexity Creep, Misplaced salience, Interface Design, System Capability, System Design, Procedures, Reliability and Robustness, Data Integrity
Team	Communication, Coordination, Roles and responsibilities, Team Cohesion, Attitude, shared mental models, Trust and Collaboration.
Tasks/ Domain	Information Overload, Lack of required information, Quality of information, Fragmented Information, Complexity, Automation, Workload, Workflow
Environment	Environmental stressors (Loud Noises, Lighting Conditions, Thermal Discomfort, Air Quality, Large Crowds, etc.), Complexity of the environment

Diagnosing FM work system for SA-related issues

To be innovative and efficient in the fast-changing demands and needs of client organizations, FM work systems must adopt strategies for continuous adaptation and improvement of the work systems (Duffy, 2000; Roberts, 2001; Nazali and Pitt, 2009). This necessitates adopting a problem-solving approach to identify poor performance outcomes/challenges within the work system, define problems, and design and implement solutions throughout the work system's life cycle. Poor performance outcomes in the work system can directly be attributed to poor SA, provided the actors can and are willing to decide and act with their SA (Endsley, 2020). This indicates that addressing SA-related issues in the work system can improve its performance. In order to achieve that, one should conduct a comprehensive diagnosis, which can guide interventions aimed at enhancing SA. The existing literature predominantly focuses on descriptive assessment of SA, which can describe whether a work system holds required and accurate SA or not. There are also few supports available in terms of guidelines for system design to support situation awareness (Endsley et al., 2003; Alhaider, 2022). However, we do not find any evidence of support available for diagnosing the work system for SA-related issues. Diagnosis in complex work systems demands systems thinking (Senge, 1994; Testa and Sipe, 2006; Wilson, 2014). The literature review discovered the iceberg model of systems thinking and its potential and applicability in diagnosing various work systems (Al-Homery et al., 2019; Ttr and Sivakumar, 2019). The researchers modified and adapted the iceberg model to guide the diagnosis of SA-related issues in the FM work system. (Refer to Figure 3 for details). For the scope of this research, we limit the diagnosis to one layer down to the iceberg model, where it uncovers patterns of individual, environmental, team, task/domain, and technological factors impacting situation awareness in FM work systems. Future work should focus on identifying mental models and sociotechnical interactions responsible for the emergence of SA-impacting factors in the FM work systems.

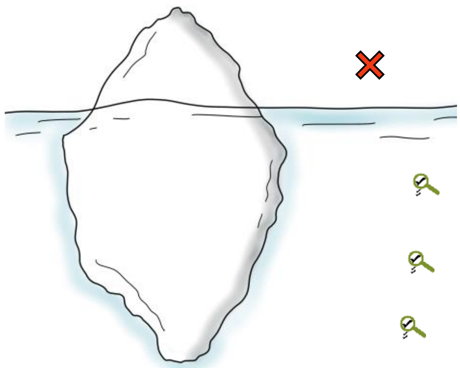

Figure 3:Iceberg model of systems thinking for diagnosing FM work system for SA-related issues.

Methodology

The ergonomic and human factors domain suggests integration of methods with a systems approach to address complex problems of sociotechnical systems (Stanton, 2018; Salmon and Read, 2019). With this inspiration, based on the literature review of situation awareness, sociotechnical systems, and facility management domains, we propose a qualitative method to support diagnosing FM work systems for situation awareness-related problematic situations. Figure 4 shows overall research methodology to be adopted for this research.

With a focus on improving situational awareness in FM work systems, the literature review on situational awareness comprehensively lists the factors that impact SA. The literature review on situation awareness touches on the different aspects of the sociotechnical systems, i.e., individuals, teams, technologies, tasks/domains, and the environment. Based on the different aspects of the sociotechnical systems, the corresponding factors that impact SA have been reviewed and listed in the Table 2. Based on the factors listed from the literature, the FM work system is investigated using the proposed method, which integrates multiple methods (see Table 3). Furthermore, while evaluating the FM work system with the proposed method, there could be a possibility of new factors that result from the diagnosis that are also included while diagnosing the work system. Overall, at meta level the method itself can be evaluated and improved for its effectiveness for FM work system but this is beyond the scope of this research work.

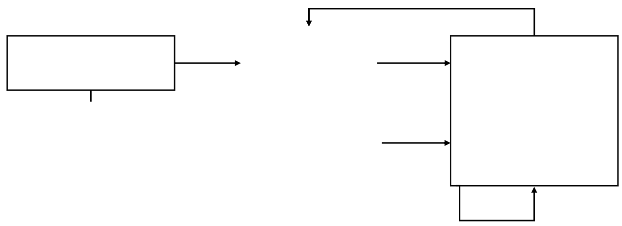

Figure 4:Adopted Research Methodology

Table 3: Proposed research method for diagnosis of the FM work system for SA related issues

Phases	Objectives	Activity	Outputs	Involvement of Participants
Data Collection	To understand the work system thoroughly	In-depth interviews, direct observations, system and operators' logs	Recordings, Notes and documents	Provide relevant information
Data Processing	To prepare data for analysis	Transcription and documentations	Documents	Not Required
	To identify and define potential problematic situations in the work system	Qualitative Analysis Who? What? When?	List of Problems	Verification of Problems for their occurrence
Data Analysis	To identify problems relevant to Situation Awareness and related possible causal factors	Reasoning How? Why?	Problems relevant to SA and related causal factors	Active Involvement in Reasoning
Interpretation of results	To interpret the results of the analysis	Visualization	Frequency Distribution of Responsible SA impacting factors	Not required

Case Study

The applicability of the proposed method was tested in an industrial FM setting. The industrial setting had multiple work systems like water management, helpdesk, energy, access control, security, etc. Out of the different work systems, the helpdesk work system is central to the efficient functioning of the different work systems together. Recent trends in FM emphasize the adoption of a helpdesk for the large and complex built environment with many occupants to process work orders, complaints, and service requests of the clients effectively. The principle of helpdesk systems is similar to the IT helpdesk – "to respond to a customer's inquiry as quickly as possible and follow it through until it has been satisfactorily resolved". However, the functioning of the helpdesk work system in the FM domain can be complex and challenging, as it deals with a large problem space with multiple interrelated support team networks and a complex-built environment. In this regard, the helpdesk work system was chosen as the place of interest for the study. The unit of analysis for this study was the whole helpdesk work system with two helpdesk executives and a facility manager responsible for its functioning, as shown in the Figure 5

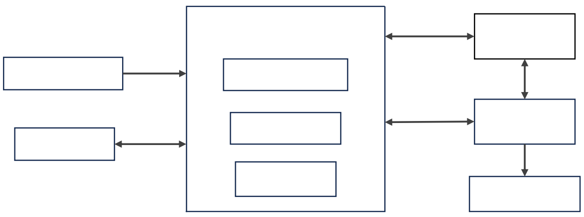

Figure 5:Basic structure of the FM helpdesk work system.

The study began with an informal discussion among the researchers and the help desk executives with two major objectives: for the researchers to familiarize themselves with the operations of the help desk work system and for executives to familiarize themselves with the study plan. After the informal discussion, the researchers conducted observational studies at different times to understand and record the basic functioning of the work system. Two separate questionnaires (See Table 4 and Table 5) were prepared to conduct semi-structured interviews with helpdesk executives and the facility manager to thoroughly understand the work system and its problems. The three and half-hour overall interviews were recorded and transcribed. The transcripts of the interview and the notes of the observational study were used together to do a qualitative analysis to understand the detailed functioning of the help desk work system and identify potential problematic situations. A more precise description of the problems was prepared with an understanding of who is involved, what the problem is, and when it occurs in the work system. Precise description helps to improve understanding of the problems, which supports the relevant stakeholders' diagnosis of the work system. These problems were revisited to check their uniqueness, relevance to SA and duplications were removed. The helpdesk executives further verified the problems identified for their occurrence. Diagnosing each problem was performed with reasoning to identify all possible causal factors that can impact SA in the work system by the researcher. This was done carefully with the factors identified in the literature and newly realized factors from the reasoning activity.

Questionnaires:

These questionnaires were prepared for semi-structured interviews to understand the helpdesk work system thoroughly as shown in Table 4 and Table 5.

Table 4:Questionnaire for Semi-structured Interview of Helpdesk Executives

Questions
What is your association with the Facility Management Work System?
Can you briefly explain the helpdesk work system?
Can you describe your role and responsibilities related to the helpdesk work system?
What is your work experience related to your current role? How do you gain experience?
What are your day-to-day operations at work? Are there any specific tools or software you use?
Do you work as a team? What is your specific role in this team?
Have you or your team identified any training or skill gaps required to improve your performance?
What reporting and documentation processes do you follow to keep track of system performance, issues, and resolutions?
How do you communicate with other stakeholders to address issues or to seek support?
How do digital tools and equipment impact your daily operations?
What issues do you face in the daily operations related to digital tools and equipment?
What are the anticipated risks if the issues are not resolved?
What improvements or changes could be made to enhance the efficiency and effectiveness of your role as an operator of this solution/system?

Table 5:Questionnaire for Semi-structured Interview of Helpdesk Work System Manager

Questions
Can you provide an overview of the facility management helpdesk work system's structure and its role within the organization?
What are the primary objectives and goals of the facility management helpdesk work system in ensuring smooth facility operations?
Could you describe the key processes and workflows the helpdesk team follows to manage facility requests and issues?
What are the key performance indicators (KPIs) or metrics used to measure the success and efficiency of the facility management helpdesk?

What are the most common challenges or bottlenecks the helpdesk team encounters in addressing facility-related issues?

How are facility requests and issues assigned and tracked within the helpdesk system, and what tools or software are used for this purpose?

How does the helpdesk team coordinate and communicate with facility management staff and other relevant departments to resolve issues promptly?

How is the helpdesk equipped to handle unexpected facility-related emergencies or disruptions effectively?

What technologies or tools support the facility management helpdesk's work processes and decision-making?

How do you ensure your helpdesk team has the resources and training to manage facility requests and issues effectively?

What strategies and practices are in place to continuously improve the facility management helpdesk's operations and service delivery?

How are conflicts or issues typically managed and resolved within the helpdesk team or with other facility-related stakeholders?

Can you share recent examples of successful facility management initiatives or improvements facilitated by the helpdesk team?

What future developments or changes do you foresee for the facility management helpdesk, and how are you preparing for them?

How does the helpdesk gather and utilize feedback from facility users and staff to enhance its service quality and efficiency?

What leadership and management style do you employ to ensure the success and satisfaction of the helpdesk team?

Are there any specific training or development needs you believe would benefit the helpdesk team's performance in managing facility requests and issues?

How does the facility management helpdesk contribute to fostering a positive facility management culture and ensuring high levels of user satisfaction?

Can you share experiences where the helpdesk effectively responded to critical facility-related situations or challenges?

What are the most important lessons you have learned as a leader of the facility management helpdesk, and how have they influenced your approach?

Results:

A total of seventy-one potential problematic situations related to poor performance outcomes were identified, and diagnosis was performed to identify related SA-impacting factors obtained from the literature and through analysis. Figure 6 shows the frequency distribution of the SA impacting factor relevant to the identified problematic situations in the FM helpdesk work system in decreasing order where ineffective communication and lack of knowledge and experience are the highest occurring factors, this could be the case as the industrial setting is in under digital transformation and very frequently new facilities and related teams are being introduced. Ineffective feedback mechanisms, the complex network of actors, lack of accountability, lack of multidisciplinary knowledge, work constraints, lack of standardization, and poor data handling are the new factors realized with reasoning activity in the data analysis phase which can impact SA.

The environmental stressor, team attitude, goal and expectations and out-of-the-loop syndrome did not show up in the analysis. The environmental conditions were well maintained in terms of lighting and air quality. Also, a dedicated space is allocated to the helpdesk team which lacks large crowd and loud noises. Team attitude and goal and expectations has complex relationships with SA which is difficult to put into the reasoning. The helpdesk executives were proactively engaging with the other relevant actors to get and provide updates which avoids out-of-the-loop syndrome.

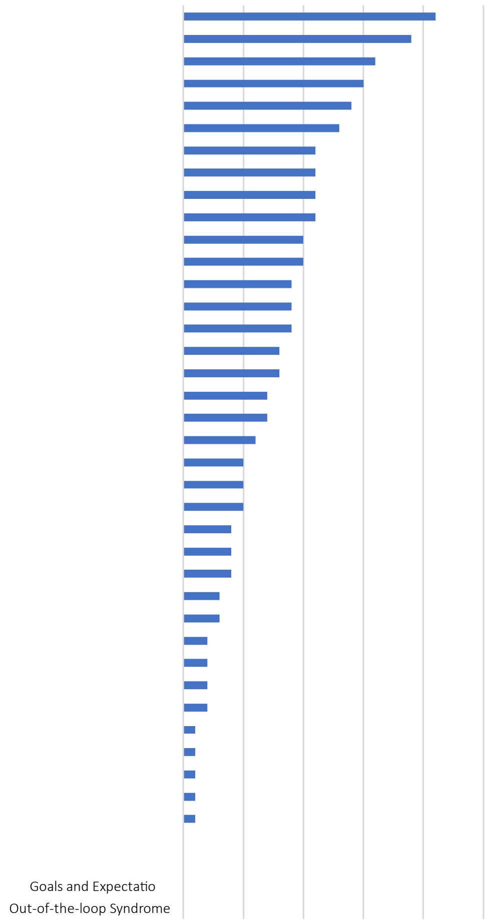

Figure 6: Frequency Distribution of the SA impacting factors from analysis.

Discussion and Conclusions

The method discussed in the study stemmed from the initial observations and discussion with relevant FM stakeholders of a help desk system in an industrial FM setting. These observations underscored the significant impact of poor situational awareness (SA) on the efficacy and functionality of the help desk system, prompting a comprehensive diagnosis of the underlying work system to enhance SA. The work system managers spend substantial time and effort in diagnosing the work system through routine meetings and discussions, but they were not found to have a situation awareness-oriented approach. From Figure 3, they mostly react to the poor performance outcomes for surface-level solutions, but the literature suggests it requires systems thinking to understand the underlying cause and treat them. This highlighted the critical need for thorough analysis and diagnosis of FM work systems to address underlying challenges for SA effectively.

An adequate understanding of all the factors impacting situational awareness is essential for the stakeholders to diagnose the FM work system. Some of the factors that impact the FM work system may be difficult to reason out, requiring comprehensive reasoning ability of the stakeholders, for example, how goals and expectations and team attitude can affect SA. The result of the analysis represents how responsible each factor is in impacting SA; it should not be confused with how much impact a particular factor causes to SA in the work system. This analysis of the FM work system acts as a reference point to further investigate the underlying interaction through which the SA-impacting factors emerge in the system. While the involvement of stakeholders in the process is ideal, practical considerations such as time constraints may necessitate analysis by the researchers alone, where they are expected to have a detailed understanding of the work system. Furthermore, it is necessary to ensure that stakeholders are well-supported and informed about the different steps and factors in understanding the method in advance to facilitate their effective participation.

Although the suggested approach has shown itself to be useful in the setting of a help desk work system, more research should be done to see whether it can be scaled up to include a greater number of participants and other work systems. Expanding the methodology's scope to include a wider range of stakeholders and organizational contexts would offer important insights into its effectiveness for various FM work systems while it may also demand large efforts. We anticipate the potential for developing digital tools to support the effective use of the method by system stakeholders where the tool's knowledge base can be enhanced with each study, it can support reasoning, and the involvement of the researcher can be avoided. Furthermore, the analysis presented in the study is from the researcher's perspective owing to the constraints of time and availability of the systems stakeholders. As the study is a work in progress, a comprehensive analysis of the problematic situations of the help desk work systems from the active participation of stakeholders is something that needs to be looked at in future works.

[3]Gulf University for Science & Technology, Mishref, Kuwait

Abstract

This study addresses construction safety by deploying computer vision techniques, specifically a YOLOv8 model by Ultralytics, to monitor PPE compliance. Targeting helmets, vests, and safety shoes, it aims to mitigate accident risks. The model was trained with 2934 images and validated with 816, achieved a 95% mAP. Emphasizing AI's potential in safety management and occupational health in the construction industry. This research lays groundwork for future AI-based safety enhancements in construction sector, highlighting the industry's pressing need for innovative approaches to reduce occupational hazards and improve compliance standards.

Introduction

The construction industry, known for being the primary driver to infrastructure development been consistently ranked among the most dangerous industries worldwide, with a high incidence of accidents and fatality rates making it one of the most hazardous sectors (Lingard, 2013; Pinto et al., 2011; Waehrer et al., 2007). High rates of accidents and fatalities have been consistently reported, many attributable to non-compliance with safety measures, particularly the use of Personal Protective Equipment (PPE) (Memon et al., 2023; Sehsah et al., 2020). In many incidents, the lack of PPE or improper use of safety gear such as helmets, vests, and boots has been a critical factor. (Kang, 2018) reported that more than 70% of all fatal accidents had some form of incompliance with PPE. This persistent challenge highlights a gap in safety protocols and enforcement on construction sites, highlighting the need for more stringent and effective monitoring tools to ensure worker safety and reduce the risk of accidents.

Given the high importance of maintaining safety standards and reducing injuries from accidents in construction sites along with the prevalent safety challenges, it is necessary to rethink traditional methods and employ innovative technologies to enhance safety compliance rates on sites (Zhang, 2021). Among these technologies, artificial intelligence (AI) takes the lead when it comes to the development of object detection systems specifically for PPE in the site (Abioye et al., 2021). On a site, monitoring systems using AI can assist safety engineers in achieving higher compliance of safety due to the fact that traditional human supervision can sometimes be expensive, prone to error and insufficient in maintaining safety standards (Yi and Wu, 2020). Such systems can aid in the detection of workers who are not complying with safety standards mainly, wearing proper PPE while working on sites. The necessity for improved safety compliance on construction sites, coupled with the inadequacies of traditional safety monitoring methods dictates the need to start integrating AI-driven object detection systems in construction sites. The integration of AI-driven systems in construction sites represents an important opportunity and a significant leap forward in terms of technology adoption within the construction industry.

This paper is part of a larger project that aims to utilize AI in the construction sector. The project is divided into several phases where the objective of this phase is to answer the following research question (RQ).

RQ – Are fine-tuned object detection models, specifically YOLOV8 efficient and effective in identifying safety helmets, safety shoes and vests in construction sites?

Literature Review

Safety risks in the construction sector

The construction engineering sector is a key driver of economic growth in both developed and developing nations (Sánchez et al., 2017). Despite advances in workplace safety within the construction sector, it still faces a greater risk of injuries and deaths than many other industries (Johansson et al., 2019). According to the US bureau of labor statistics (BLS), more than 1 in 5 deaths occurred in the workplace was within the construction industry in the year 2020 with a reported number of 1,008 construction workers that were killed on the job (A Look at Workplace Deaths, Injuries, and Illnesses on Workers' Memorial Day, 2022). Each year, more than 100,000 individuals suffer from fatal injuries each year within the construction industry as per the International Labor Organization (ILO) which alone, represents about 30% of all occupational fatal injuries ("Construction," 2015).

A recent study (Memon et al., 2023) highlights that substandard quality of PPE is a leading cause of accidents in the construction industry. This study also found that the use of PPE can reduce accidents related to falls by 30%. Another study indicated that many accidents on construction sites occur due to the lack of PPE or failure to wear it properly (Ammad et al., 2021). Despite approximately 62% of construction workers being at risk of falls, only about half use PPE, as reported by the Bureau of Labor Statistics (BLS) (A Look at Workplace Deaths, Injuries, and Illnesses on Workers' Memorial Day, 2022). Furthermore, it was noted that over 70% of fatal fall accidents involved workers not wearing PPE (Kang, 2018). Additionally, according to the Health and

Safety Executive (HSE), there are more than 9,000 PPE-related accidents annually on construction sites in the United Kingdom. Understanding the frequency of these incidents underscores the need to educate employees on the importance of proper PPE usage (Martin et al., 2021). Severe brain injuries on construction sites, primarily caused by falls and falling objects, are a significant concern (Kamardeen and Hasan, 2022). Furthermore, the Centers for Disease Control and Prevention (CDC, 2011) estimates that almost half (49%) of all fatal injuries in this sector are due to head injuries (Occupational Ladder Fall Injuries — United States, 2011).

The concerning statistics and studies highlighted in this section emphasize the urgent need for more stringent and effective enforcement of PPE safety compliance in the construction industry (Ebekozien, 2021; Gattuso, 2021). It is imperative to develop and implement reliable strategies to ensure that workers are adequately protected, thereby reducing the high incidence of injuries and fatalities that currently plague this sector.

Technology adoption and integration in construction industry

The potential of Artificial Intelligence (AI) is increasingly being recognized across various sectors. However, its adoption and application in the construction industry are scarce compared to other industries. As a matter of fact, the construction industry ranks among the least digitized sectors globally, and a common misconception among stakeholder exists regarding the industry's longstanding culture of resistance to change (Young et al., 2021). Additionally, the lack of technology integration in the construction industry is often associated with health and safety concerns (Nikas et al., 2007). In an effort to address this slow growth in adoption, many companies are now turning to Artificial Intelligence (AI) as a means to streamline their processes and boost productivity within the working environment (Yigitcanlar, 2021; Yigitcanlar and Cugurullo, 2020). The adoption of AI technology grants a competitive edge in terms of automation when compared to conventional approaches (Chien et al., 2020). Within the wide variety of AI-Based technologies, the application of computer vision through deep learning has shown promising potential in construction safety management. The object detection capability of AI provides flexibility in terms of classifying and recognizing objects, which is something to be capitalized upon to improve safety compliance. This technology, serves a foundation to effectively substitute human vision for many tasks across the construction safety workflow (Abioye et al., 2021). This sets the stage for exploring advancements in AI for PPE compliance monitoring in the next section.

Advancement in AI for PPE compliance monitoring

In recent years, the construction industry has seen significant advancements in the application of Artificial Intelligence (AI) for safety management, particularly in monitoring Personal Protective Equipment (PPE) compliance. The effectiveness of AI, specifically deep learning, and computer vision, in real-time monitoring of safety helmets and PPE compliance, showing promise for enhanced on-site safety have been demonstrated in the literature (Delhi et al., 2020; Kisaezehra et al., 2023).

Recent advancements in the construction industry's approach to safety management have been significantly influenced by the application of Artificial Intelligence (AI). A focus on enhancing Personal Protective Equipment (PPE) compliance has been evident, with AI-driven systems, particularly those incorporating YOLO models for object detection, demonstrating notable accuracy and real-time capabilities. This shift towards AI-based methodologies for safety gear recognition, especially through the use of advanced YOLO v5 and v8 models, underscores a growing trend in leveraging technology to improve on-site safety measures (Chen et al., 2021; Kim et al., 2023; Wang et al., 2023).

The advancements in AI for construction safety have seen significant strides in the development of systems for detecting safety helmets and protective clothing. A notable approach involves the enhancement of YOLOv3 methods, specifically tailored to improve the detection of smaller-sized safety gear. This innovation, focusing on the addition of a large-size input layer for multi-scale prediction, represents a crucial step in fine-tuning AI models to meet the unique demands of construction site applications, underscoring the critical role of AI optimization in specific industrial contexts (Wang et al., 2020).

The exploration of AI in the construction industry has further expanded with the introduction of rapid PPE detection systems for actual construction sites, utilizing deep learning techniques. This advancement, as presented in the literature, signifies the practicality and effectiveness of AI in enhancing real-time safety management on construction sites. It addresses the critical requirement for advanced and efficient safety monitoring tools within the industry, showcasing the potential of AI to significantly improve construction safety practices (Wang et al., 2021).

Together, these studies underscore the potential of AI and machine learning, particularly YOLO models, in revolutionizing safety compliance in the construction industry. They highlight the technical feasibility and practical implications of deploying AI systems for real-time, accurate PPE monitoring, marking a significant step forward in occupational safety management.

Closing remarks

As indicated by the literature, to the best of the authors' knowledge, there has been limited empirical research examining the adoption of AI technologies in the construction industry. As such, this study aims to contribute to the growing body of knowledge surrounding the integration of artificial intelligence, namely, PPE compliance detection systems in the construction industry.

Methodology

Development of the PPE Compliance AI model – YOLOV8

You Only Look Once V8 (YOLOV8), developed by Ultralytics in January 2023, served as the foundation for our AI model. YOLOV8 is a convolutional neural network (CNN), that is a category of deep learning neural networks, commonly used in analyzing visual imagery. YOLO was trained and validated using a dataset, namely Common Objects in Context (COCO). The COCO dataset contains more than 330 thousand images of 80 different common objects, including but not limited to, humans, bicycles, cars and animals. A total of 118 thousand images were used for the training, 5000 for validation and 20 thousand for testing. The model was then benchmarked against the validation dataset using the mean average precision (mAP) which is basically a percentage precision of the number of detected objects correctly identified across multiple objects (Ultralytics, 2023a). YOLOV8 can be used for different purposes, including object detection, object tracking, object classification and segmentation. The project utilizes the object detection capabilities of YOLOV8.

Currently, there exists five YOLO models with varying sizes, (1) Nano, (2) Medium, (3) Large, (4) Extra Large. Simply put, smaller models compromise accuracy for speed, and are useful where computational power is limited and speed is a necessity. On the contrary, the larger models are the most accurate, but also the most resource intensive. According to Ultraltytics documentations, mAP is 37.3 and 53.9 for the Nano and Extra-large model respectively (Ultralytics, 2023b).

Based on the limited computational power available, and the fact that the model is aimed to run in real-time, the YOLOV8 (m) model was used, with a mAP of 50.2. The (m) model offers a middle ground between speed and accuracy with a good balance between performance and efficiency.

YOLOV8 (m) fine tuning

While COCO is a well-established dataset, it fails to serve the purpose of the project, therefore, a custom dataset was required. Following Ultralytics recommendations, two main folders were created, a folder dedicated specifically to the training dataset and a folder dedicated to the model validation. Within each directory, two subfolders were created, namely “Images” and “Labels”. All the training images that were collected were inserted in the “Images” subfolder under “Train” main folder. On the other hand, the images used for validations were inserted in “Images” subfolder under the “Validation” main folder. A total of 2934 images and 816 images were for training and validation respectively. Figure 1 shows the breakdown of the dataset organization.

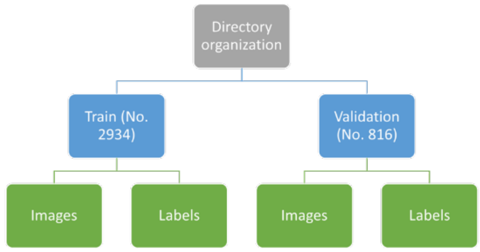

Figure 1: Directory organization for the customized training

The 2934 images collected were to fine tune the model to detect if a construction worker, within a construction site setting is adhering to the PPE requirements. The object detection model aims to detect if workers are wearing their safety helmets, vests, and safety shoes. The open-source images were collected in addition to taking photos using a phone camera in construction sites after taking consent from safety officers. To avoid bias in the image collection, the data collected was made sure to be as diverse as possible, encompassing different colors and shapes of helmets, vests, and safety shoes with varying backgrounds ensuring transferability of the model across different countries.

After the collection of the photos, the fine-tuning process begins. First, Conda, an open-source package management and environment management system was downloaded and installed in which all the machine learning is managed. A dedicated environment was created using Conda where all the packages required for YOLOV8 were installed. Using the command “pip install ultralytics” downloads all the packages and dependencies required to run YOLOV8. Prior to installing the packages concerning YOLOV8, it is necessary to annotate the images in the “Train” and “Validation” folders and save the output into the “Labels” subfolder of both “Train” and “Validation”. For that, “LabelImg”, an open-source graphical image annotation tool, was downloaded and installed. Labelling the images using “LabelImg” outputs a .txt file for each image with the location of the label within an image. Figure 2 shows the user interface and the labelling using “LabelImg".

Figure 2: LabelIMG annotation user interface

The annotation process involved six classes:

- Class 0 – “Helmets”

- Class 1 – "Vests"
- Class 2 – "Safety shoes"
- Class 3 - "No vests"
- Class 4 - "No helmets"
- Class 5 - "No safety shoes"

Upon annotating all the images collected, a ".yaml" file was prepared where the train and validation directory were set, the number of classes and the names of each class in order. This file is necessary as it contains all the necessary information required to override the existing trained YOLOV8.

An important parameter to consider before initiating the training, is the number of epochs required, that is basically one complete pass of the entire training dataset through the algorithm. Zhang et al., (2019) underscores the importance of setting the number of epochs to an acceptable and reasonable number. For example, a very small number of epochs can result in an underfitted model, meaning that the model has not been trained enough on the trained data, thus resulting in a poor performance against validation or testing data. Conversely, overfitting phenomena can occur in the cases of an exaggerated number of epochs. In such cases, the model memorizes the training set rather than generalizing. The model would ultimately perform well on the trained data but poorly on unseen data.

Selecting the appropriate number of epochs is an iterative process requiring several trials. The number of epochs for the project was set to 100 and the performance was constantly checked against the validation dataset setting an early stopping parameter in case there is no improvement in the performance as the number of epochs continues to increase. The command used in the Conda environment to conduct the training was as follows "yolo task=detect mode=train epochs=100 data=data_custom.yaml model=yolov8m.pt imgsz=640".

Figure 3 summarizes the whole processes followed to create the custom model.

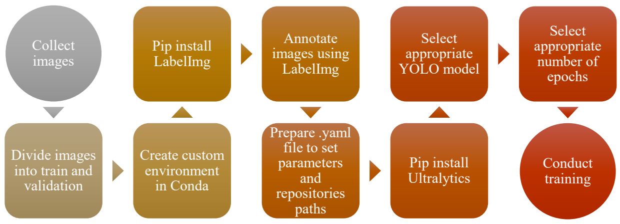

Figure 3: Summary of the fine-tuning on custom dataset.

Results and Discussion

The results and discussion section summarizes the findings of the methodological approach conducted.

YOLOV8 (m) was selected as the foundation for the fine-tuning process. A total of 2934 and 816 photos were used for the training and validation respectively. A processor of Intel® Core (TM) i9-9980HK CPU @ 2.40GHZ (16CPUs), with a dedicated graphics card of NVIDIA RTX 2060 and 32 GB RAM served as the training hardware.

By default, a patience value = 50 is set, where the numerical value represents the number of epochs. The patience parameter simply means that while the training is in process, the model shall check its performance against the validation dataset, in any case where no improvement is perceived in the last 50 completed epochs, an early stop is employed. As a result, the YOLOV8 fine-tuning process took 23.33 hours and had an early stop at 96 epochs, as there was no improvement seen beyond 46 epochs.

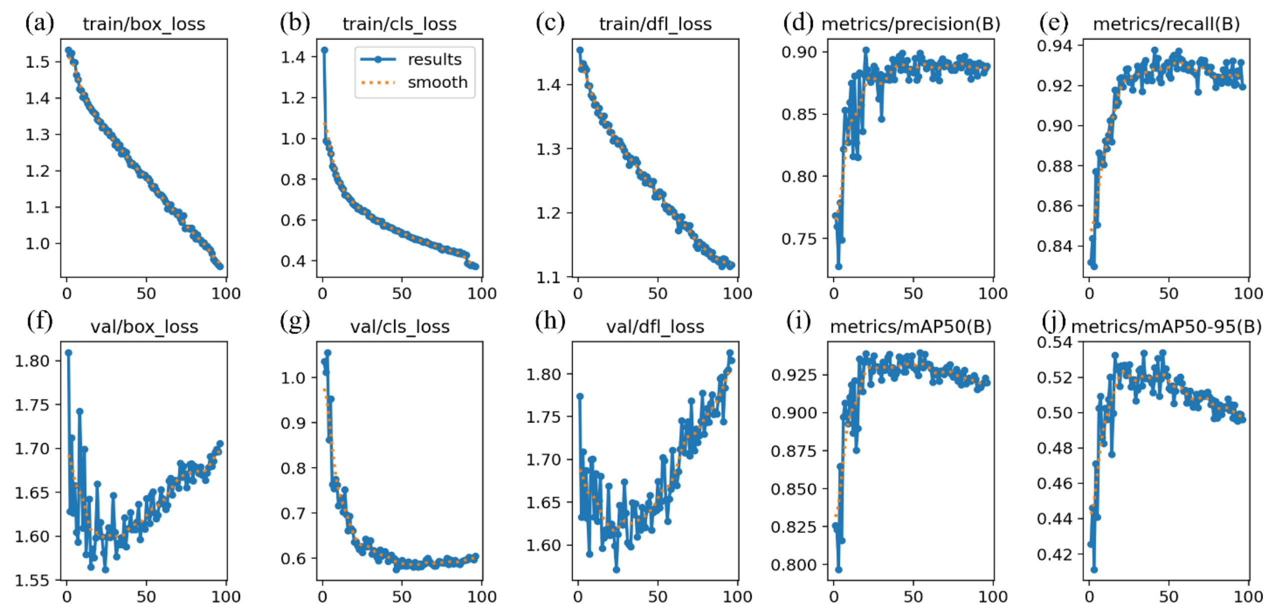

Figure 4: Training dashboard against the validation dataset

Figure 4. illustrates the results of the custom trained model from the validation dataset. The x-axis represents the number of epochs, while the y-axis varies depending on the graph it represents.

A total of 10 graphs (a) – (j) are shown in Figure 4. Figure 4 (a) – (c) and Figure 4 (f) – (h) shows the “box loss”, “cls_loss” and “dfl_loss” that correspond to box loss, classification loss, and directional focal loss on the training and validation dataset respectively. Box loss measures how well the model is predicting the bounding box coordinates for each detected object. It can be seen as the number of epochs increases, Figure 4 (a) – (c) decreases illustrating a downwards trend. This means that the model gets better at defining the coordinates of the binding boxes, improving its ability to detect the orientation of the objects along with their presence. Though, when considering Figure 4 (f) – (h) it can be seen that all three figures see improvement in the box_loss, cls_loss, and dfl_loss up to the 46th epochs. This confirms the early stop and patience parameter were beyond the 46th epochs, there was no improvement seen. The change in the figures trend indicates a sign of overfitting. When the validation loss starts to increase while the training loss continues to decrease, it means that the improvements in the model are specific to the training data and are not improving the model’s predictive ability for new, unseen data.

Figure 4 (d) – (e) shows the precision and recall changes through 96 epochs for the validation dataset. Both Figures (d) and (e) show a positive and linear trend against the epochs. Once the training hits the 46th epochs mark, the precision reaches its highest value of 0.89/1 and 0.92/1 for the recall. The training continues all the way to the 96th epochs where the value of the precision and recall falls to 0.88/1 and 0.91/1 respectively. The precision level shows that the model, at the 46th epochs is precisely detection the correct object 89% of the time. On the other hand, a recall of 92% indicates that the model is able to recall 92% of the objects.

Figure 4 (i) – (j) shows the mean average precision and the mean average precision at 95% at Intersection over Union (IoU). Similar to Figure 3 (d) – (e), the figures here look at the average precision per class. In addition, IoU of 95% is considered a very stringent threshold, it means that for a detection to be considered to be a true positive, the predicting bounding box must overlap with the ground truth bounding by at least 95%. Only detections that satisfy this threshold is considered true positive. On the 46th epochs, the mean average precision at 95 % IoU is 0.53/1.

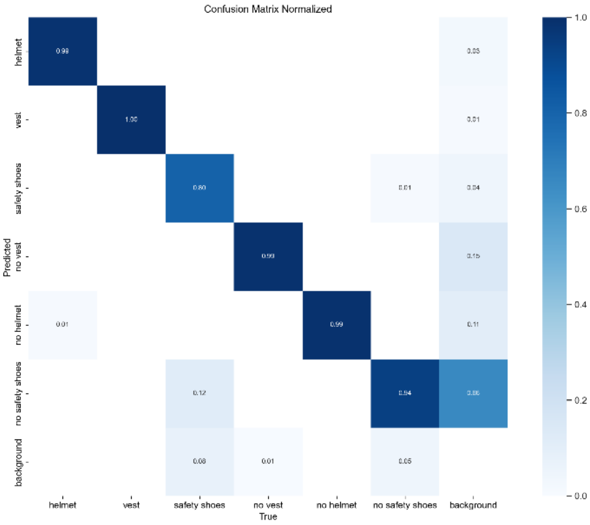

Figure 5: Normalized confusion matrix

To further understand the model reliability, and to visualize the performance of the algorithm, a normalized confusion matrix is shown in Figure 5. The matrix shows that the model predicted 'helmet' with 99% accuracy indicating true positive. Moreover, the 'vest' class has been predicted by the model with high accuracy. As for 'safety shoes', the true positives were 80%, but there were some instances where it predicted 'safety shoes' when there were none indicating false positives, and some instances where it failed to predict 'safety shoes' when there were some (false negatives). This can be due to the fact that normal shoes may emulate the look of safety shoes designs which can lead to false positives. It can also be mentioned that there are very few cases where the model indicated a 1% of false positives in helmets. While this result indicates high precision, it is limited to the used dataset.

The confusion matrix suggests that the model is quite effective at predicting 'helmet' and 'vest' classes, is fairly good at predicting 'safety shoes', and generally does not confuse items with the background. However, there are some areas where the model can generate false predictions, particularly with the 'safety shoes'. This information can be used to refine the model further, potentially by providing it with more training data for the classes where it is less accurate or adjusting the model's parameters.

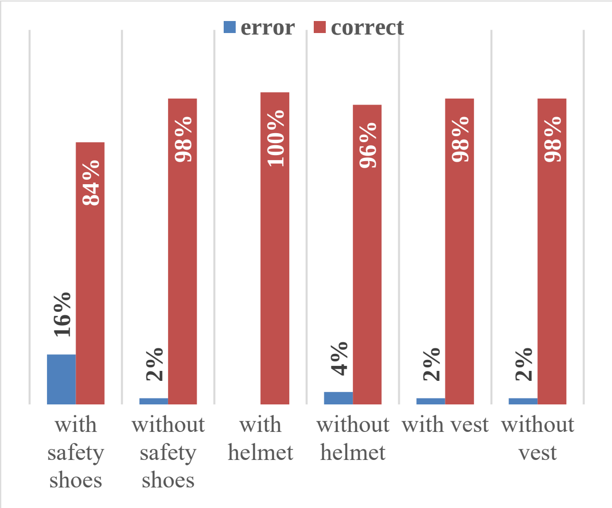

Figure 6: Results of YOLOV8 (m) "Best.pt" model against testing dataset

Figure 6 presents the performance results of the YOLOV8 (m) "Best.pt" model when evaluated against a testing dataset to detect various types of PPE. The figure illustrates and compares the percentage of correct identifications against the percentage of error across the six classes discussed before across 300 photos of workers complying or not in construction sites. All the 300 photos used for testing were exclusive to the testing dataset and were not used in the training nor the validation dataset.

The model clearly demonstrates high levels of accuracy in detecting the presence of a helmet, with a score of 100% and no perceived errors. Similarly, detecting vests achieved a 98% accuracy and success rate. The 'without helmet' category shows a slight decrease in accuracy of 4% error rate only which could be improved by further training the model. However, the model's performance exhibits a notable decline in the 'with safety shoes' category, with a correct identification rate of 84% and a corresponding error rate of 16%. This suggests that while the model is highly effective at identifying vests and helmets, it finds safety shoes more challenging, which may indicate a need for further model training or data augmentation in this category specially since safety shoes can exhibit a diverse number of models, colours and shapes.

The mAP for the testing dataset can be calculated by finding the average of all the precision from the 6 classes. A percentage of 95.6 was obtained, indicating a similar mAP to the validation dataset.

The error rates presented in the graph are essential for understanding the model's limitations and guide future improvements to enhance its predictive capabilities for PPE compliance on construction sites. It is important to note that since the testing data was only from 300 photos, the results cannot be considered reliable. Furthermore, construction sites are dynamic with variations in settings, lighting conditions and working environment. This illustrates the need to diversify the collected data to cover wider landscapes of conditions. A possible solution is using data augmentation techniques to transform images and simulate different lighting conditions.

Figure 7: PPE detection of sample in-test photo

Figure 7 demonstrates the PPE detection model's output when using the YOLOV8 (m) fine-tuned model. Each class is bounded by a box which states the confidence level of the PPE detection. The confidence level represents how accurately is the model detecting and determining the class of the PPE in use within the detection frame. While the testing was only conducted on images, the model can be utilized with a high-resolution camera to be tested and implemented in real-time scenarios.

Conclusion and Limitations

This research endeavor has illustrated the core hazards within the construction industry, examining the critical concerns concerning Personal Protective Equipment (PPE) safety standards. It highlights the necessity of upholding stringent safety compliance on construction sites to mitigate the risk of accidents and enhance worker protection.

Additionally, this study has detailed the capabilities of object detection technologies, namely, YOLO technique's robust framework. The analysis revealed that the YOLOV8 is balanced between precision and computational efficiency, particularly when utilizing a dataset of medium size to fine-tune the trade-off between speed and accuracy. The model's effectiveness at identifying compliance with helmet, vest, and safety shoes requirements in PPE protocols was notable, although it did exhibit a potential for enhancement in detecting 'safety shoes' class type.

The model is limited to the collected dataset which illustrates a need to increase the size of the training data, specifically, safety shoes. In addition, it is worth noting that the testing data was limited to 300 images which does not necessarily cover all real-world scenarios. Data augmentation techniques can further enhance the collected dataset to cover wider working conditions in construction sites. These insights not only validate YOLOV8's utility in practical applications but also identify specific possibilities for refining the model to achieve even higher levels of accuracy in PPE detection in future phases.

This stage of the conducted research was limited to the development of the AI-based PPE detection system. In the forthcoming stage of our research, a case study approach can be implemented to further investigate the model reliability. The focus will be on evaluating the impact of deploying the AI-based PPE compliance monitoring system within construction environments in real time. This assessment will illustrate the system's efficacy in reinforcing adherence to PPE usage standards and protocols. Moreover, we intend to conduct a thorough investigation into the sector's behavior in response to the system's implementation and acceptance.

While AI-based PPE compliance monitoring comprises privacy, it is essential to consider an ethical framework. Construction companies willing to implement this technology must obtain consent of workers being surveilled and implement anonymity approaches such as face blur techniques to preserve the privacy of workers. In addition, the reports generated by the AI model should be inspected against bias. Decision makers within the construction industry must be aware that the intention of such systems is to augment manual inspection and not replace it.

Acknowledgment

The authors would like to express their sincere gratitude to the Australian University – Kuwait for their support of the ongoing research. Special thanks are extended to Abdullah Jalal Jamal, Zainab Hani Jamal, Sherifa Meshal Borhamah, and Noryah Saeed Alqabadni for their exceptional efforts, without which this project would not have been possible.

Abstract

This study assesses the integration of technology in the construction sector to address labor shortages. Traditional methods show deficiencies in coping with workforce deficits. A survey design was employed, utilizing exploratory and inferential statistical techniques, including a two-step cluster analysis, Spearman's rho, and Mann-Whitney U tests, to examine the relationship between firm size, technological implementation, and productivity in the construction industry. Results indicate that larger firms leveraging technology report higher productivity. This study's contribution lies in highlighting technology's role in mitigating labor shortages and enhancing productivity, with implications for strategic industry decision-making and policy development.

Introduction

The construction industry is currently experiencing a severe global labor shortage (AGC, 2022), resulting in increased costs and delays in projects. This scarcity of skilled workers poses widespread challenges, escalating expenses, and prolonging timelines for construction projects globally. Addressing this issue is pivotal for mitigating its impact on finances and project completion timelines (ABC 2023).

Since the 1980s, the North American construction industry has consistently faced a shortage of skilled labor, exhibiting cyclical patterns over the past three decades (Karimi et al., 2018). This shortage, influencing the national economy and citizens' well-being, is tied to the overall performance of the U.S. economy, with construction demand fluctuating accordingly (Al-Bayati et al., 2020). The increased demand for construction services has led to a critical labor issue, affecting both skilled and unskilled workers, resulting in project delays, cost escalations, and compromised project quality. In this context, the research conducted by Sadeh et al. (2021) becomes particularly relevant. It highlights the industry's division into conventional and avant-garde firms in response to technological and market changes. Sadeh (2023) further underscores the industry's productivity lag due to insufficient digitalization, a challenge particularly acute for small and medium-sized firms. Additionally, Sadeh et al. (2022) reveal the underutilization of Building Information Modeling (BIM) in large U.S. construction firms, indicating a gap in digital proficiency. These studies collectively underscore the need for increased technology integration and digital proficiency in the construction industry. At the same time, the construction labor market's complexity requires a comprehensive approach to understand and address these challenges (Cheung et al., 2011). Additionally, the Department of Labor's concern over the aging workforce and the need for approximately 240,000 new workers underscores the importance of attracting and training a new generation to sustain industry growth and adapt to evolving demands (Kim et al., 2020). Despite its substantial contribution to global economic development—accounting for 9% of GDP and employing 7% to 8.5% of the workforce worldwide—the construction industry struggles with low productivity and minimal technological advancements (Hossain et al., 2020). Global construction spending, which reached USD 11.4 trillion in 2018 and is expected to rise to USD 14 trillion by 2025, contrasts starkly with the industry's mere 1.5% investment in technology in the U.S., significantly lower than that of manufacturing (3.3%) and the overall economy (3.6%) (Changali et al., 2015). This discrepancy is particularly notable given that productivity in construction has largely stagnated, in contrast to the manufacturing sector, which has nearly doubled its productivity. Contributing to these performance challenges, as identified by Gupta (2019), are factors such as regular payment delays, advancements in technology, labor efficiency, and the availability of skilled professionals, all of which are pivotal in shaping the outcomes of construction projects.

In response to the prolonged labor shortage and improving production quality, the construction industry is increasingly embracing technology. Major firms are not only establishing innovation departments and investing in new technologies but also conducting on-site product testing (Jackson, N.D., 2020). There is a growing interest and application in various forms of automation such as virtual reality, augmented reality, drones, robotic arms, reduced scanning/photogrammetry, and 3D printing, all actively researched and utilized, albeit often confined to specific projects (Hossain et al., 2020). In addition to these technologies, the Internet of Things (IoT), drones, and prefabrication are emerging as game-changers due to their cost-effectiveness and minimal disruption to traditional construction practices, thereby shaping the future of construction job sites (Jackson, N.D., 2020). Complementing these technological advancements Cai et al.'s research (Cai et al., 2018; Cai et al., 2019) delves into the application of automation and robotics in high-rise construction, addressing labor shortages and safety risks. Moreover, Halder et al. explored the integration of inspector assistant quadruped robots (Halder et al., 2023) and developed a computational framework for remote navigation of these robots, integrating live-streaming and AR with BIM models (Halder et al., 2022). Goh et al. (2019) conducted a detailed simulation study of modular construction operations, known as Prefabricated Prefinished Volumetric Construction (PPVC), in Singapore. Their work provides valuable insights for future applications in offsite construction research. These advancements highlight the industry's increasing reliance on technology to tackle labor shortages and improve productivity. However, the path to technological integration is not without its challenges. These include the critical task of evaluating the investment value of new technologies and overcoming resistance from tradesmen who might view certain technologies as inefficient or unnecessary (Jackson, N.D., 2020). In addition to these practical challenges, the industry faces broader issues such as low productivity and limited technological progress, especially evident in Digital Twin (DT) applications, as highlighted by Opoku et al. (2021). Naderi & Shojaei (2022) further underscore the complexities of infrastructural projects and the nascent nature of digital twins, pinpointing the lack of consensus among stakeholders as a major barrier to the adoption of infrastructure digital twins (IDTs). To address production issues in construction, Antunes et al. (2018) proposed a framework integrating automatic supervisory control and data acquisition, while also noting the often-isolated implementation of information technology and automation within the industry. Melenbrink et al. (2020) explored the challenges in achieving fully autonomous construction in unstructured environments, stressing the need for development across all construction task groups and coordination between task-specific robots. On the sustainability front, Adaloudis et al. (2021) utilized grounded theory methods to assess the benefits of 3D concrete printing (3DCP), with a focus on balancing environmental, economic, and social sustainability aspects. Their research indicates that firms are increasingly motivated to invest in technologies like 3DCP to enhance automation and address skilled labor shortages. Furthermore, Liu-Lastres et al. (2022) analyzed the causes and effects of the Great Resignation, concentrating specifically on labor shortages in the construction industry and proposing various strategies to manage these challenges effectively.

The primary aim of this study is to investigate how construction firms are utilizing technology to navigate the challenges of labor shortages and how this strategy influences their operational dynamics. It is driven by two core research questions: First, it seeks to understand the ways in which technology is leveraged to address labor shortages within the construction industry and how this approach interacts with variables such as firm size, project type, and productivity to shape the firms' operational profiles. Second, it examines the impact of technology usage on the productivity of construction firms, exploring the potential for a notable relationship between the size of these firms and their levels of productivity. These research questions will provide insights into strategic decision-making and policy development in the face of labor shortages.

Research Questions

RQ1: How are construction firms leveraging technology to address labor shortages, and how does this strategy interact with firm size, project type, and productivity to define their operational profiles?

RQ2: How does the use of technology to mitigate labor shortages affect the productivity of construction firms, and is there a relationship between the size of these firms and their productivity levels?

Hypothesis 2A (Firm Size and Productivity)

- **H_1:** There is a monotonic relationship between firm size and productivity in construction firms.

Hypothesis 2B (Technology Usage and Productivity)

- **H_1:** There is a statistically significant difference in the median productivity scores between construction firms that use technology to mitigate labor shortages and those that do not.

Methods and Materials

The methodology is comprised of the design and implementation of a survey instrument as a component of a comprehensive electronic questionnaire. The questionnaire was developed based on an extensive literature review to assess workforce development within the construction sector and was formed as part of a broader research initiative. In the comprehensive survey conducted, a total of thirty-seven questions were presented to participants, encompassing demographic information, organizational insights, and practices, as well as technology adoption strategies. However, for the scope of this article, focused analysis was conducted on a subset of these questions that directly contribute to our examination of workforce development challenges and the role of technology in mitigating labor shortages within the construction sector. These questions were selected based on their direct relevance to our research objectives, which underscored their importance in addressing the core themes of our investigation. The rationale for focusing on these questions is further supported by their potential to illuminate the key dynamics of workforce development and technology integration in the construction industry. The first section contained multiple-choice questions related to the demographics of respondents and company profiles. The second section comprised closed-ended yes/no questions and Likert scale items ranging from 1 to 5. The respondents were asked to rate the productivity of both their craftsmen and office personnel. Additionally, they were also questioned about their adoption of technology as a strategy to counter labor shortages. For those affirming the use of technological solutions, the survey further delved into identifying the specific types of technologies being employed. Prior to its distribution, a pilot study was conducted to evaluate the validity and reliability of the survey questions, ensuring the instrument's effectiveness in accurately capturing the relevant data. Based on the findings, certain questions were revised or removed. Data collection occurred over a three-week period at CM Expos and job fairs organized for construction management students on three university campuses across the United States, located in Virginia, New York, and California. These events attracted 270 companies, including both national and regional contractors, and provided a valuable opportunity for data gathering. The process was designed to secure a representative sample of the industry. The questionnaire, however, was only distributed to around 125 construction firms, of which 92 responses were received, and 86 were complete and deemed suitable for analysis, resulting in a response rate of 73.6%. Based on the research goals and questions, appropriate exploratory and inferential statistical techniques were employed and analyzed using SPSS 29. A two-step cluster analysis was conducted for Research Question 1, while Spearman's rho and Mann-Whitney U were used for Research Question 2. The demographics of the respondents and the companies' profiles are shown in Tables 1, 2, 3, 4, and Figure 1 below. Most of the firms were commercial contractors with revenues encompassing $500 million per year.

Table 1:Roles of Respondents

Role	Frequency	Percent
Project Manager	20	23.3
Field Engineer	6	7.0
Project Engineer	17	19.8
HR	10	11.6
Superintendent	6	7.0
Executive Leader	25	29.1
BIM Specialist	2	2.3
Total	86	100.0

Table 2: Experience of Respondents

Duration	Frequency	Percent
Under 5	36	41.9
6 - 10	14	16.3
11 - 15	10	11.6
16 - 20	6	7.0
21 +	20	23.3
Total	86	100.0

Table 3: Firm Size

Employees	Frequency	Percent
1 - 49	7	8.1
50 - 249	26	30.2
250 - 499	20	23.3
500 - 999	15	17.4
1000+	18	20.9
Total	86	100.0

Table 4: Project Type

Type	Frequency	Percent
Commercial	50	58.1
Residential	8	9.3
Heavy Civil	15	17.4
Mix-Use	8	9.3
Institutional	5	5.8
Total	86	100.0

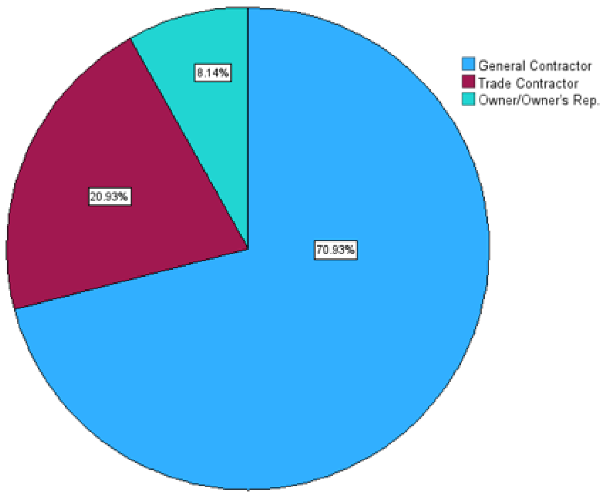

Figure 1:Firm Type

Results and Discussion

Usage of Technologies in the Industry (RQ1)

Figure 2 below shows the types of technologies that construction contractors are utilizing to mitigate the impact of workforce labor shortages.

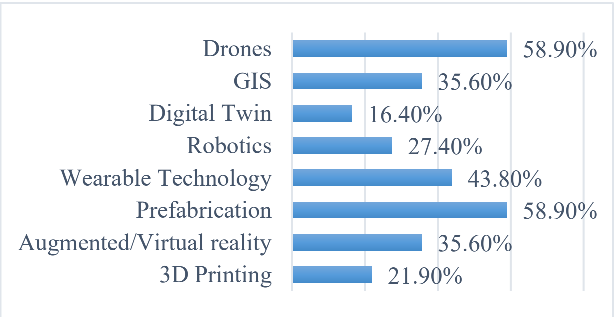

Figure 2:Technology Type

Drones and Prefabrication are the most widely adopted technologies, both at 58.9%. This suggests a significant trend in the construction industry towards automating and streamlining processes. Drones can be used for surveying, monitoring job sites, and ensuring that projects are progressing as planned while offsetting tasks usually performed with manual labor. Prefabrication indicates a shift towards constructing parts of buildings in a controlled environment before being transported to the site, improving efficiency, and requiring less on-site labor. Wearable technology emerges as another significant contributor, with 43.8% of industry professionals integrating it into their operations. This category includes advanced gear such as exoskeletons, which alleviate physical strain on workers, and smart helmets that enhance operational efficiency through real-time data delivery. The integration of such technology not only compensates for labor deficits but also promotes worker safety and productivity. Both Geographic Information Systems (GIS) and Augmented/Virtual Reality (AR/VR) are being utilized by 35.6% of respondents. GIS is used for planning and managing construction projects, while AR/VR can be used for training purposes and to visualize projects before they are built, which can reduce the need for rework and thus the demand for additional labor. Further, Robotics are being used by 27.4% of the respondents. Robots can perform tasks such as bricklaying, welding, and even more complex construction activities, which helps to alleviate the need for skilled labor. At 21.9%, 3D printing technology is adopted by a fifth of the respondents. This technology can be used to create building components or even entire structures with less manual labor required. Lastly, Digital Twin technology, while currently the least adopted at 16.4%, holds a significant promise for the future of construction and represents a significant undeveloped potential. This technology creates a virtual replica of physical construction sites, allowing for meticulous planning, real-time monitoring, and maintenance which, in turn, can lead to a more efficient allocation and utilization of labor.

Firms' Segmentation and Operational Profile (RQ1)

The two-step cluster analysis was utilized to categorize firms into five distinct groups, leveraging the inherent groupings that arise from variations in key variables within the dataset. This analysis considered four variables: Firm Size; Technology Usage, which indicates whether firms employed technology to mitigate labor shortages; Project Type; and Productivity, a continuous variable that measures the output of craftsmen and office personnel, including project managers, estimators, schedulers, and project engineers. The analysis resulted in five unique clusters as shown in Figure 3, with Figure 4 providing a graphical representation of the relative distribution of these clusters based on the four variables. Cluster 1, accounting for 17.4% of the sample, included medium-sized firms with 250-499 employees. These firms uniformly utilized technology and primarily engaged in heavy civil projects, recording a productivity total of 6.93. Cluster 2, which accounted for 15.1% of the firms, consisted mainly of small firms with 1-49 employees. Most of these firms did not use technology and focused on commercial projects, achieving a productivity total of 6.00. Cluster 3, representing 24.4% of the sample, included medium-scale commercial technological firms with 500-999 employees. These firms had a complete adoption of technology and closely matched Cluster 1 in productivity total with 6.95. Cluster 4 comprised 25.6% of the firms, including small-to-medium-sized firms (50-249 employees) that fully adopted technology and specialized in commercial projects, with a productivity total like Cluster 3 of 6.95. Finally, Cluster 5, which included very large firms with over 1000 employees, formed 17.4% of the sample. Most of these firms were technology users focusing primarily on commercial projects and showed the highest productivity total of 7.47. The segmentation indicated by the results is marked, with firm size, technology adoption,

Cluster	4	3	1	5	2
Size	25.6% (22)	24.4% (21)	17.4% (15)	17.4% (15)	15.1% (13)
Inputs	Firm Size 50 - 249 (100.0%)	Firm Size 500 - 999 (57.1%)	Firm Size 250 - 499 (46.7%)	Firm Size 1000+ (93.3%)	Firm Size 1 - 49 (46.2%)
	Technology Usage Yes (100.0%)	Technology Usage Yes (100.0%)	Technology Usage Yes (100.0%)	Technology Usage Yes (86.7%)	Technology Usage No (92.3%)
	Project Type Commercial (68.2%)	Project Type Commercial (81.0%)	Project Type Heavy Civil (60.0%)	Project Type Commercial (73.3%)	Project Type Commercial (53.8%)
	Productivity 6.95	Productivity 6.95	Productivity 6.93	Productivity 7.47	Productivity 6.00

Figure 3: Grouping of Clusters

project type, and productivity levels acting as distinguishing characteristics. Clusters 3, 4, and 5 demonstrated a strong technological integration, suggesting a trend towards digital transformation, especially among medium to very large firms. Clusters 1 and 5, which include the larger firms, reported higher productivity totals, implying a possible link between firm size and productivity, potentially attributable to economies of scale or greater resource investment in adaptation and process optimization. Notably, Cluster 2 stands out as the sole group where most firms did not embrace technology, coinciding with the smallest firm size and the lowest productivity, highlighting the critical influence of technology adoption on productivity.

The analysis of predictor importance, presented in Figure 5, provides valuable insights into the relative impact of each variable on the cluster assignments. Firm Size emerged as the most significant predictor, suggesting that the number of employees is a fundamental factor in differentiating the clusters. This emphasizes the role of firm size in operational practices, as well as its potential influence on the adoption of technology and the types of projects undertaken. Following in significance was Technology Usage, which stands as the second most critical predictor. This underscores the influence of digital adoption on how firms are classified, reflecting the centrality of technology in shaping business operations and productivity within the industry. Project Type also played a moderate role in the clustering, indicating that the nature of projects—whether commercial or heavy civil—has a discernible, though lesser, effect on the grouping of firms compared to size and technology usage. Productivity, while relevant, was the least influential predictor in the clustering process. This suggests that productivity, as a performance metric, does not contribute to cluster differentiation as strongly as the other variables, potentially because it is impacted by firm size and technology usage to an extent that limits its independent variation across clusters.

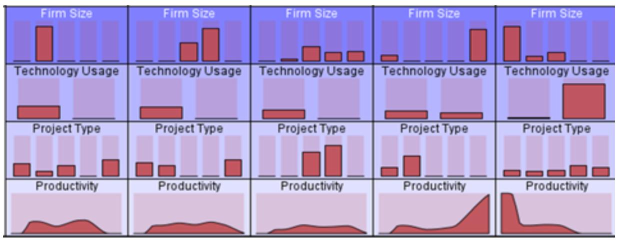

Figure 4:Relative Distribution of Clusters

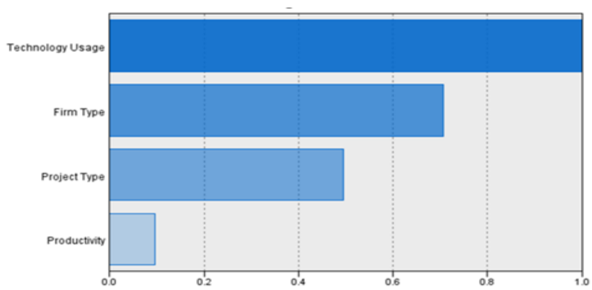

Figure 5: Predictor Importance

Impact of Technology on Productivity (RQ2)

In the context of examining the impact of technology usage on the productivity, the construction firms, particularly as a strategy to combat labor shortages, the Mann-Whitney U test provides a non-parametric means for assessing whether the median productivity scores differ between technology-using firms and non-technology-using firms. This test is particularly apt for situations where the data does not satisfy the assumptions necessary for a traditional t-test, such as non-normal distribution or ordinal measurements, as is the case with the sample for this study. The analysis incorporated 72 firms, shown in Table 5, that reported using technology to mitigate labor shortages, compared to 14 firms that did not employ technology for this purpose. The Mann-Whitney U test results revealed a mean rank of productivity of 46.19 for the technology-using firms, with their cumulative ranks summing up to 3326.00. Conversely, the non-technology-using firms exhibited a lower mean rank of 29.64, with a summed rank of 415.00. The marked disparity in the mean ranks suggests that firms engaging in technology tend to report higher productivity. The Z-score associated with the test statistic was -2.341, which indicates that the observed ranks are 2.341 standard deviations below the mean rank sum that would be expected under the null hypothesis of no difference between the groups. Crucially, the asymptotic significance (two-tailed) value was 0.019. This p-value is indicative of the probability of obtaining the observed results, or more extreme, under the null hypothesis that there is no difference between the two groups' median productivity. Since the p-value is less than the conventional alpha level of 0.05, the null hypothesis can be rejected at the reference confidence level. This implies that the difference in productivity ranks between firms using technology and those that do not is statistically significant. Therefore, the statistical analysis suggests a clear association between the implementation of technology and increased productivity among construction firms. The implication of this finding is that technology usage appears to be an effective measure in addressing labor shortages within the industry, as evidenced by the higher productivity rankings among firms that adopt technological solutions. This conclusion aligns with the ongoing narrative within the sector that technology not only serves as a stopgap for labor deficit but also enhances operational efficiencies and outputs. These results can guide industry stakeholders in decision-making processes regarding investments in technology to combat the pervasive challenge of labor shortages.

Impact of Firm Size on Productivity (RQ2)

This analysis sought to determine the relationship between firm size and productivity within the construction industry. Utilizing Spearman's rho, shown in Table 6, to measure the strength and direction of association between these two ordinal variables, we observed a correlation coefficient (rho) of 0.215.

Table 5:Mann Whitney Test

Technology Usage		N	Mean Rank	Sum of Ranks	Mann-Whitney U	Wilcoxon W	Z	Asymp. Sig. (2-tailed)
Productivity	Yes	72	46.19	3326.00	310.000	415.000	-2.341	0.019
	No	14	29.64	415.00				
	Total	86						

a. Grouping Variable: Technology Usage

This positive correlation, while weak, indicates that larger firms tend to have slightly higher productivity levels. Notably, this association was statistically significant (p = 0.047), suggesting that the observed relationship is unlikely to have occurred by chance. Therefore, we reject the null hypothesis in favor of the alternative hypothesis, concluding that there is evidence of a monotonic relationship between firm size and productivity in the population from which the sample of construction firms was drawn. Given the sample size of 86 firms, these findings provide some evidence that firm size may be a factor in productivity outcomes in the construction sector. However, given the modest strength of the correlation, further research should explore additional variables that might influence productivity more strongly.

Table 6:Spearman's rho Test

			Firm Size	Productivity
Spearman's rho	Firm Size	Correlation Coefficient	1.000	.215*
		Sig. (2-tailed)	.	.047
		N	86	86
	Productivity	Correlation Coefficient	.215*	1.000
		Sig. (2-tailed)	.047	.
		N	86	86

*. Correlation is significant at the 0.05 level (2-tailed).

Conclusion

The comprehensive analysis presented in this study offers important insights into how construction firms are leveraging technology to mitigate labor shortages and the subsequent impact on productivity. Particularly, the study's findings underscore the prevalence of technological adoption across the construction sector, with a particular emphasis on drones and prefabrication as leading strategies. The data suggests a strong relationship between firm size, technology usage, project type, and productivity, with larger firms demonstrating an inclination towards higher productivity levels, potentially reflecting the benefits of economies of scale and enhanced resource allocation.

The segmentation of firms into five distinct clusters highlights the nuanced ways in which these variables interplay to shape operational profiles within the industry. Firms that embrace technology, particularly those of medium to large scale, show a clear trend towards higher productivity totals, reinforcing the narrative that digital transformation is a key driver of efficiency and output in the face of labor challenges. In contrast, the standout characteristic of the smallest firms—many of which have not adopted technology—correlates with the lowest productivity scores, emphasizing the pivotal role of technology in enhancing productivity. Empirical findings from the Mann-Whitney U test and Spearman's rho analysis further validate the hypotheses set forth at the outset of the study, i.e., confirming a statistically significant difference in productivity between firms that utilize technology and those that do not, as well as a positive correlation between firm size and productivity. However, the study's conclusions are offered with the acknowledgement of several limitations. The method of data collection, primarily through university job fairs, could potentially introduce a selection bias. This is because firms participating in these fairs might be inherently more inclined towards innovation and technological advancements, while leveraging employment shortages, possibly skewing the sample towards more technologically progressive companies. Another key limitation lies in the reliance on self-reported data, which carries an inherent risk of reporting biases, as firms might tend to overestimate their productivity or the impact of their technological implementations. Lastly, the cross-sectional design provides a snapshot that cannot capture the dynamic nature of technology adoption over time. Despite these limitations, the findings suggest that the construction industry is actively adapting to labor challenges through technology, and the high response rate reinforces the reliability of this conclusion. This research has significant implications for industry stakeholders, suggesting that investments in technology are not only a viable response to labor shortages but also a critical component of enhancing overall firm productivity. The study’s insights are valuable for informed strategic decision-making and policy formulation aimed at improving growth and sustainability within the construction sector. Future research should aim to build upon these findings, exploring the broader implications of technology adoption and firm size on productivity, with an eye towards identifying other contributory factors that could further refine our understanding of these complex dynamics.

DIGITAL BUILDING LOGBOOKS AND STAKEHOLDER MAPPING: A CROSS-SECTORAL APPROACH TO DATA COLLECTION AND SHARING

Sun-Ah Hwang[1]
[1]Department of Management in the Built Environment, Delft University of Technology, the Netherlands

Abstract

Digital building logbooks (DBLs) are designed to provide a platform to ease data sharing among stakeholders between and beyond the architecture, engineering, construction and operation (AECO) sectors. However, there is a gap in understanding among stakeholders regarding their roles and the overlaps and differences in the data they need. With the findings from qualitative research, the paper provides a new framework to DBL stakeholder mapping that facilitates the identification of stakeholders necessary for effective data exchange and efficient decision-making at different phases across the building lifecycle. This approach defines the roles of the stakeholders as data providers, data users or both, providing an initial impression to how building data can be sourced into and out of the DBL. The paper ultimately demonstrates the relevance of building data for all identified stakeholders, emphasizing the importance of a cross-sectoral involvement in DBLs.

Introduction

The European goal to increase the current renovation rate of 0.4-1.2% to 3% has been challenged by several barriers (Gómez-Gil et al., 2022). One such barrier often overlooked in literature is the lack of building data.

The limitations in the availability, reliability and storage thereof have been viewed as recurring impediments in the decarbonization of the built environment; namely when evaluating the real state of buildings, measuring decarbonization progress, advocating the urgency of retrofits, and during decision-making for planning renovation and maintenance (Monzón & López-Mesa, 2018; Blum, 2009; Talamo & Bonanomi, 2015).

The lack of building data sees great urgency, though it has rarely been addressed in literature (Gómez-Gil et al., 2022). While there is a continuous inflow of new building data, there still seems to be a lack of data particularly on the existing building stock. Gomez-Gil et al. (2022) describe the problem of data loss and unavailability as a "multidimensional problem which affects all scales: local, national, and European". Locally at municipal level, it is still a problem in European member states that the issuing of construction and renovation licenses is paper based, increasing risks of information loss and limiting possibilities of information processing and sharing. Where old but digital data is available, they are "available in spreadsheets or flat tables [and] linkages between them [are] not possible" (Formosa & Pace, 2022).

To provide an indication on the potential extent of the shortage in building data, the Housing Europe Observatory (2023) reported that dwellings built before the oil crisis in the 1970s accounted for 25-67% of the total stock in the 27 European countries studied. It can be deduced that if data and information on these dwellings are available at all, the likelihoods of them being dated, out of context, one-off, not in digital or easily changeable formats, (very) partially covered and/or has adopted a questionable research methodology are significantly high.

What should be stressed here is that the existing housing stock exceeds that of the new in most developed countries (Housing Europe Observatory, 2023). For instance, in the Netherlands, new constructions account for less than 1% of the existing housing stock each year (Centraal Bureau voor de Statistiek, 2023a, 2023b). This means that today's existing housing stock will account for at least 70% of the total building stock in 2050. Therefore, decarbonizing the available housing stock should be prioritized when concerning the 2050 climate goals.

To overcome building data loss and to increase the data accessibility and interoperability, Digital Building Logbooks (DBLs) were first introduced at the European level to address the fundamental issue of data loss and unavailability that is grounded on the asymmetric and obsolete way of data collection by all relevant stakeholders involved (Gómez-Gil et al., 2022). The DBL is designed to record and trace every change made to a building across its lifecycle, including but not limited to changes in ownership, tenure or use, maintenance and refurbishments. It is intended to be a dynamic tool that enables improved logging, management and accessibility of all data, information and documents on buildings. For that purpose, it holds "administrative documents, plans, description of the land, the building and its surrounding, technical systems, traceability and characteristics of construction materials, performance data such as operational energy use, indoor environmental quality, smart building potential and lifecycle emissions, as well as links to building ratings and certificates" (European Commission et al., 2020, p. 12).

The proposal to use the DBLs to promote and design building renovation processes, on the other hand, is recent (Gómez-Gil et al., 2022). It was recognized in the Renovation Wave Strategy as an autonomous tool to contribute to "create better conditions for staged renovation[s]" (European Commission, 2020). From what started off as a digital repository, DBLs have since evolved to bear the capacity to convert building data into actionable information for all relevant stakeholders. Essentially, the DBL is founded on the grounds that all information and data stored in DBLs are easily shared between and beyond the stakeholders of the architecture, engineering, construction and operation (AECO) sectors.

However, the built environment and construction sector are traditionally fragmented with the immense numbers of stakeholders involved. These stakeholders often have conflicting interests; the difference in information needs, use of data and purposes is inevitable. Data that is relevant and of value to every stakeholder involved is often unavailable in one place and a systematic approach to organizing and managing it is largely missing. The challenge thus lies in the gap in the understanding among stakeholders of the overlaps in the data they need in common, as well as the significance of their roles in DBLs and the larger ecosystem.

This paper therefore aims to address the gap in stakeholder understanding in the context of building data in DBLs, emphasizing the importance of cross-sectoral collaboration in data collection and sharing. This paper results in a new framework mapping DBL stakeholders that clearly highlights the importance of engaging stakeholders from both within and beyond the AECO sectors to ensure that: (1) the DBL is used at its full capacity, (2) reliable data is available and can be accessed in DBLs and (3) stakeholders recognize the urgency for cross-sectoral collaboration in data collection and sharing.

Research Methods

The research involved a literature review and qualitative research, in addition to the synthesis of the results from the two methods through stakeholder mapping.

To understand the scope of all internal and external stakeholders involved, this paper first builds on the findings from several EU studies on DBLs. As a starting point, the early report on the development of a European Union framework for DBLs by European Commission et al. (2020) defined and identified the key stages of a building lifecycle wherein the role of DBLs is significant, as well as 17 stakeholder groups from across the entire construction and built environment value chain involved in the process.

This list of stakeholders was refined and categorized in the subsequent DG-GROW project led by Ecorys et al. [1], which aims to develop a European model for DBLs to promote tools and protocols that enable data sharing and usage throughout the construction ecosystem. In their final report, Ecorys et al. (2023) grouped the stakeholders into five main user categories and outlined their potential DBL use based on their needs.

This paper then expands on the initial desk findings through two-part qualitative research: a survey questionnaire and a series of focus group sessions. The online survey questionnaire (65 respondents) was conducted to explore the (desired) roles of the stakeholders in the various DBL systems.

The second part of the qualitative research is conducted in collaboration with Demo-Blog [2]. Short for *Development and Demonstration of Digital Building Logbooks*, Demo-BLog is a Horizon Europe funded project which sees to cultivate a decision support tool that enables existing initiatives to identify optimal sustainability transition pathways that are driven by clustered DBL data. It aims to further exhibit how DBL data can serve to advance the current evaluation strategies for climate and energy transition implemented at various levels in Europe.

Demo-BLog brings together five currently operational DBLs in Europe to develop and demonstrate four diverse functionalities addressing key societal challenges, ranging from ‘quick wins’ to complex industrial transaction objectives including circularity. Table 1 provides and overview of the five DBLs and its active regions.

Table 1: The five DBLs studied in Demo-BLog (Grant agreement ID: 101091749).

Name DBL	Owning bodies	Active regions
Chimni	Chimni	United Kingdom
CLÉA	Qualitel	France
CAPSA	Chillservices	Germany, Scotland, the Netherlands, and Italy
Woningpas	VEKA, OVAM, Wonen-Vlaanderen and Departement Omgeving	Flanders (Belgium)
Cirdax	Re-Use Materials	The Netherlands and Belgium

With Demo-BLog, a series of focus group sessions were conducted to further identify individual stakeholder contributions and significance. The sessions were conducted in four regions where the DBLs studied had the most influence in: United Kingdom, Flanders (Belgium), France and Germany. Table 2 provides an overview on how the DBL is positioned in the four study regions.

Table 2: Overview of the positioning of the DBL in the four study regions (Findings from Demo-BLog).

Study regions	Positioning of the DBL
United Kingdom	The use of a DBL is not mandatory. There are six commercial providers* that together, at the UK government’s instigation, form the Residential Logbook Association (RLBA) to bring the DBLs to a common standard and promote data interoperability.
Flanders (Belgium)	The use of a centralized, government owned DBL, *Woningpas*, is mandatory for all homes in Flanders. It is automatically available for all building owners, both natural persons as well as businesses.
France	The use of DBLs for homes has been mandatory for all new buildings since 1 January 2023. Since then, a DBL must be established at moments of construction or renovation, equipped with an analysis on the environmental impact.
Germany	The use of a DBL is not mandatory. In comparison to the other regions studied, the stakeholders indicated that the lack of building data is most severe in Germany.

**Note that there are other property logbook providers that exist outside of RLBA.*

The synthesis of the review results and the empirical analysis resulted in the subsequent mapping of the stakeholders according to the phase(s) of the building lifecycle in which they are (potentially) engaged to the DBL. The analysis showed that stakeholders can be largely categorized into two groups in the context of DBL data: data users and/or providers. This approach was essential when identifying the type of data exchange that is necessary at various points in the building lifecycle, as well as how the gaps in data sourcing can be resolved with the larger involvement of stakeholders.

Literature Studies

DBLs: EU's solution to data loss and unavailability

The European Commission et al. (2020) describe that "the capturing and maintenance of data and information is the backbone of the DBL". They claim that a systematic, well-organized and standardized scheme for data collection and storage has the capacity to alleviate the following barriers that is observable in the current scene:

"Firstly, due to the absence of a systematic approach to capturing, storing, analysing and organising it, valuable data and information are lost. Secondly, the storage of data is fragmented and scattered across several organisations (and even departments within the same organisation). Thirdly, data that is collected and stored by one individual actor is not necessarily accessible and available to other actors in the value chain." (European Commission et al., 2020, p. 15).

A DBL is thus designed to improve transparency and trust between the various stakeholders involved.

DBL stakeholders as defined by early EU studies

Early European studies on DBLs conducted identified 17 stakeholder groups that are (potential) benefiters and/or contributors of DBLs (European Commission et al., 2020). Table 3 provides an overview of the list.

Table 3: 17 stakeholder groups as identified by the European Commission et al. (2020).

Stakeholder groups
Landlords and owner-occupiers (incl. prospective buyers and sellers)
Tenants
Designers
Developers
Construction contractors
Investors
Banks and insurers
Material suppliers (incl. urban miners)
Facility and building managers
Demolition contractors
Public authorities and policymakers (ie. urban planners)
Real estate agents
Researchers
Utilities
Certifiers
Lawyers, solicitors and conveyancers
Valuers

Lifecycle approach and users of a DBL

Opportunities for data collection are present at every stage of the building lifecycle, and they each exhibit different needs of data usage (European Commission et al., 2020). Naturally, every stakeholder requires access to accurate data that can seamlessly address their needs at different points of the building lifecycle. For the AECO sectors — and any other relevant— to leverage the full potential of structured data, the processed information should be transferred and available integrally throughout the entire building lifecycle. Figure 1 presents the preliminary stakeholder mapping in relation to the DBL conducted by the European Commission et al. (2021).

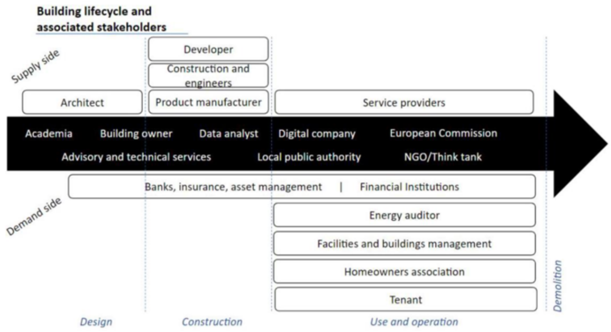

Figure 1: Stakeholder mapping in relation to the DBL (European Commission et al., 2021).

Figure 2 illustrates the simplified building lifecycle, with the phases in which the various stakeholders interact with the building defined.

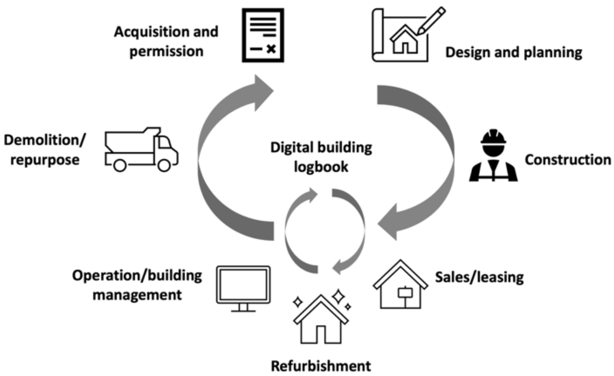

Figure 2: Simplified building lifecycle and the role of the DBL (European Commission et al., 2020).

In the context of DBLs and data, the various phases can be grouped to three larger phases (European Commission et al., 2020). Firstly, the design, planning and construction phases present the prime moment for the collection of data on the physical characteristics of the building, including information on the materials used and where they are located in the building. The collected information can then be used to prove compliance with building regulations and certification schemes (European Commission et al., 2020). Functionalities such as the construction project management can be used to ease information sharing between the various stakeholders involved, and the primary stakeholders in these phases can be said to be designers, architects, developers, contractors and material suppliers.

In the sales and/or leasing, operation and property management phases, data collection largely revolves around the operation and performance of the building. Such data may touch on maintenance, ownership transfer and change of use. The processed information can then facilitate, for instance, the identification of maintenance and renovation needs, the monitoring of user behaviour and the tracking of administrative requirements (European Commission et al., 2020). The information is likewise important for financing, as well as transaction underwriting and execution. Key stakeholders include building owners, tenants, facility managers, utility companies, real estate service providers, energy auditors, contractors and the financial sector.

The repurpose or demolition phases make use of all the data collected on the building, its composition and materials to support decision making processes when strategizing the next best step for the building; be it to refurbish, repurpose or demolish, or to optimize or extract the most value from recycling the building materials (European Commission et al., 2020). Key stakeholders include building owners, demolition companies, product maintenance service companies and recycling companies.

Considering the complexity and fragmented nature of the AECO sectors, it is evident that the data architecture of DBLs should place extra emphasis on the diversity in the data source including both legacy systems and state-of-the-art, the interoperability of the tool, as well as potential third party data processing tools and sources.

Recent findings from Ecorys et al. (2023)

In the subsequent DG-GROW project, the stakeholders that were identified by the European Commission et al. (2020; see Table 3) were grouped into five main user categories as can be seen in Table 4 (Ecorys et al., 2023).

Table 4: Five user categories as identified and defined by DG-GROW (Ecorys et al., 2023).

User categories	Primary use of a DBL
Governmental agencies (GA)	To obtain insights for policymaking, the issuing of licenses and enforcement of regulation and disaster management
Construction sector (CS)	To obtain building-related information on the design and build.
Building owners (BO)	To collect information about their buildings for exploitation and maintenance purposes.
Financial institutions (FI)	To perform analysis based on formulas to gain insight into the assets market and its developments and gain an understanding for building transactions.
Utility companies (UC)	To obtain information on the connections of utilities to the building and the analysis of its uses, and provide information related to building use or performance.

The study later developed to creating user journeys of the five user categories that highlights the (potential) use of the DBLs of each category. The exemplified user journeys of the four user groups can be seen in Figure 3.

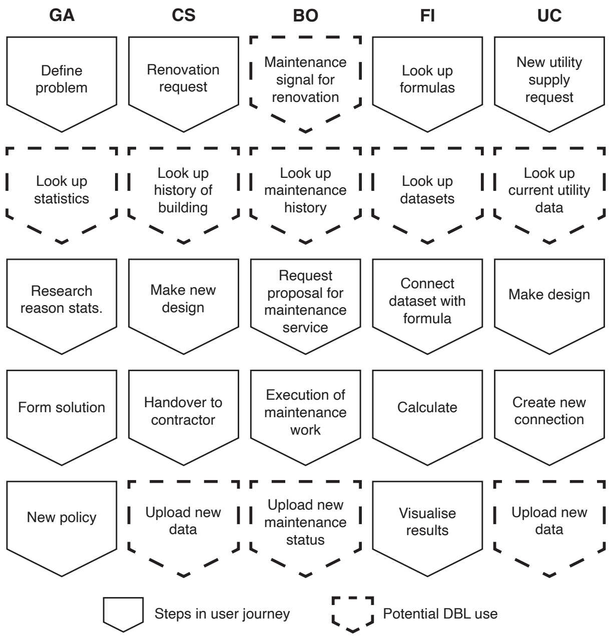

Figure 3: The exemplified user journeys of the four user categories and their potential use of the DBL (Ecorys et al., 2023).

A key finding that is significant in this study is that some stakeholders, in this case the CS, BO and UC user categories, are seen as both data users and providers. This multiplicity in the roles of the stakeholders at different phases of the building lifecycle in the DBL system provides a new light to the research on DBLs, that the two-way interaction between stakeholders and the tool, and the need for stakeholders to proactively engage with the DBL to ensure that the data stored therin is updated, accurate and remains valuable.

Survey Findings

We conducted a survey among those stakeholders identified from available literature —including but not limited to building professionals, building owners, data owners, government agencies— to identify the requirements, functionalities and benefits that are relevant to the stakeholders; for instance, data, equipment and technology, standards, and benefits such as decarbonisation, cost efficiency, resource allocation and access to trusted and traceable information. Table 5 provides a breakdown of the survey participants.

Table 5: Breakdown of survey participants in stakeholder groups.

Stakeholder group	%
Landlords and/or leaser	5
Owner-occupiers	18
Tenants (Lessees)	5
Architects and designers	5
Developers (Real-estate)	2
Banks and/or insurers	1
Building material suppliers	2
Facility and/or building managers	2
Valuers	1
Certifiers	3
Researcher	20
Public authorities	11
Policy makers	4
Other*:	21

**Other stakeholder groups as indicated by the respondents include DBL providers, service designers, data(base) companies and providers, as well as IT developers.*

Findings from the survey that is relevant to this paper can be largely categorized into two themes: data collection and data accessibility. On the former, the survey helped prove a valuable hypothesis; while stakeholders can benefit as users of the tool and the data therein, they can simultaneously play the role of data providers. Though the level of responsibilities across the data fields may differ, building owners, public authorities, building experts, financial institutions, and both public and private registers are perceived as equally valuable (potential) data providers for the efficient collection of building data.

For instance, homeowners, construction contractors, architects and facility managers are not only identified as crucial data providers for their role in updating every change made to the homes into the DBL, but are equally active data users when assessing and planning the necessary retrofit works. Government authorities can provide access to public databases that would supplement the data in the individual DBLs, while policymakers need the overview of the housing stock to efficiently distribute resources. Financial institutions, in contrast, would be active data users for efficient valuations of homes and encourage a wider roll out of DBLs in the market.

The survey also emphasized on the importance to note that the role of the stakeholder as data providers is not one-off. To ensure that the building data provided by the DBL is up to date, the regular revisions of building data is fundamental, imposing that the continuous engagement of the relevant stakeholder to the DBL throughout the entire building lifecycle is crucial.

When concerning the issue of data accessibility, the survey identified a list of third parties that could and/or should be granted access to (part of) the data a DBL holds. Several stakeholders raised here include buyers, architects, energy advisors, notaries, material and utility suppliers, estate agents, property lawyers, enterprises, financers, assurers, housing advisors and service providers. It can be deduced from this list that stakeholders across the entire construction and built environment value chain should orbit around the DBL, for the benefit of greater overall sectoral transparency, value chain integration, innovation and circularity.

Focus Group Sessions

Findings from both literature and the survey were thereafter employed in the composition of the focus group sessions with key stakeholders from four DBL-active regions: United Kingdom, Flanders (Belgium), France and Germany. Participants for the sessions were gathered through consultations with the DBL providers. 19 key stakeholders were identified as crucial contacts in the implementation and development of the DBLs across the four regions. Table 6 identifies the location and domains of the focus group participants.

Table 6: Breakdown of focus group participants.

Location	Participant	Stakeholder domain(s)
United Kingdom	1	Quality scheme
	2	Quality scheme
	3	DBL provider and DBL trade body
	4	Energy accreditation scheme I
	5	Energy accreditation scheme II and energy professional
	6	Independent climate organization
Flanders (Belgium)	1	Government climate agency I
	2	Government climate agency II
	3	Homeowner association
France	1	DBL provider
	2	DBL provider
	3	Certification scheme
	4	Consumer association
Germany	1	DBL provider
	2	Building professional (academia)
	3	Independent consultant and surveyor
	4	Climate professional
	5	Independent organization
	6	Energy innovation community

The aim of the focus groups was to study the optimal DBL performance in the respective regions. Part of the session was reserved to further distinguish individual contributions and significance of the stakeholders relevant to the operational DBLs and construction systems of the four regions. This was conducted in the form of a collective stakeholder mapping exercise, where participants of various domains in the study region collaborated in creating the matrix together.

From the focus group sessions, it was deduced that the differences in the language, operations and organizations of the construction sector, as well as the legal framework of a specific geographical region influence the defining and mapping of DBL stakeholders to a large extent. The variance in the regional positioning of the DBL and the developments of the tool in relation to the implementation and technological levels, public awareness and locally available tools —such as public databases and energy accreditation schemes— naturally increased the complexity in identifying and defining relevant DBL stakeholders in the different practical environments. Ultimately, the survey questionnaire and the focus group sessions collectively identified 38 stakeholders that are used in the subsequent mapping exercise, as can be seen in Table 7.

Table 7: 38 stakeholder groups identified from the qualitative studies.

Stakeholder groups	
Owner-occupiers	Real estate agents
Architects and designers	Investors
Construction contractors	IT providers
Certifiers	Local authorities
Public authorities	Public waste agency
Policy makers	Guarantee bodies
Facility and/or building managers	Distribution network operators (DNOs)
Landlords and/or leasers	Renovation advice providers
Researchers	Service designers (UX)
Banks and/or insurers	Retrofit service providers
Utility providers	Social housing providers
Building material suppliers	Surveyors
Developers (real-estate)	Building safety regulator
Tenants (Lessees)	Competent person schemes
Valuers	Energy data providers
Demolition contractors	Funding party
Energy experts	Maintenance contractor
Energy suppliers	International organizations
Data companies (inventories and registering)	Lawyers, solicitors and/or conveyancers

DBL stakeholder mapping exercise

With the information gathered from desk research and preliminary analysis, a mapping template was created to then compare the results with how the stakeholder roles are perceived in practice. Figure 4 (see next page) provides an overview of the combined findings of the four focus group sessions that was later validated by Demo-BLog experts.

The approach to DBL stakeholder mapping proposed in this paper builds on the approach undertaken by European Commission et al. (2021; see Figure 1). Similarly, the mapping of the DBL stakeholders in this exercise is likewise two-part: (1) distinguishing the role of a stakeholder as a data user and/or provider along the horizontal axis of the matrix and (2) identifying the phase(s) in the building lifecycle in which the stakeholder is engaged along the vertical axis.

On the former, a data user is defined to be benefiters of the building data stored in the DBL. These stakeholders need specific data to address specific needs. For instance, an owner-occupier may want to observe data on the energy consumption of the home to identify energy-saving practices. A data provider on the other hand represents the supply side of the spectrum. Taking the same example, the utility providers may either provide monthly statements on the energy consumption of the home or install meters that provide real-time information on the energy use. The significance of stakeholders of both categories is also measured in the matrix to distinguish the levels of value and contribution per stakeholder.

The phases in the building lifecycle were first defined through desk research on the preceding European studies as was discussed in earlier sections of this paper, refined later with the inputs from the focus group studies on the operational aspects of the DBLs in the regions studied.

Every stakeholder analyzed in this mapping exercise is tagged to the relevant region to provide context on the difference in stakeholder roles and significance in the locations studied. As indicated in the legend, the stakeholders raised in the discussion in Flanders (Belgium), are tagged in orange, France in blue, Germany in green and the United Kingdom in pink.

Several ambiguities were raised in the validation stage of the stakeholder mapping. Conclusions largely orbit around a common observation: there is too little overlap between the DBL active regions than was hypothesized. A number of causes were identified here:

1. Inconsistencies in the representation of the stakeholder groups during the focus group sessions;
2. The inclusion of personal aspirations rather than reflect how the DBLs are used at volume; and
3. Gaps in terminology due to differences in processes and language.

However, the exercise itself proved that a critical reflection into the AECO sectors as well as the legal and operational systems in specific regional contexts is fundamental when defining the stakeholders of the DBL.

For instance, the roles of the competent person schemes, guarantee bodies and existing renovation advice and/or service providers in the renovation phase of the building are unique in the United Kingdom, while these roles are most likely present in different entities in other regions. In Flanders on the other hand, energy experts and the public waste agency exhibited great interest in the available DBL data in both the pre-use and the end-use phases of the building to identify how the (newly) available resources can be redistributed.

Being able to identify how the roles are dispersed across unique legal systems and the various steps involved has shown to help create discourses around the DBL and the possibilities of data sharing among stakeholders of different domains. Such discourses are crucial to close the gap in understanding among these stakeholders to not only increase efficiency in the collection of building data, but also the awareness on the significance of their roles in DBLs and the larger ecosystem to ensure that the collaboration between the sectors is present. The common

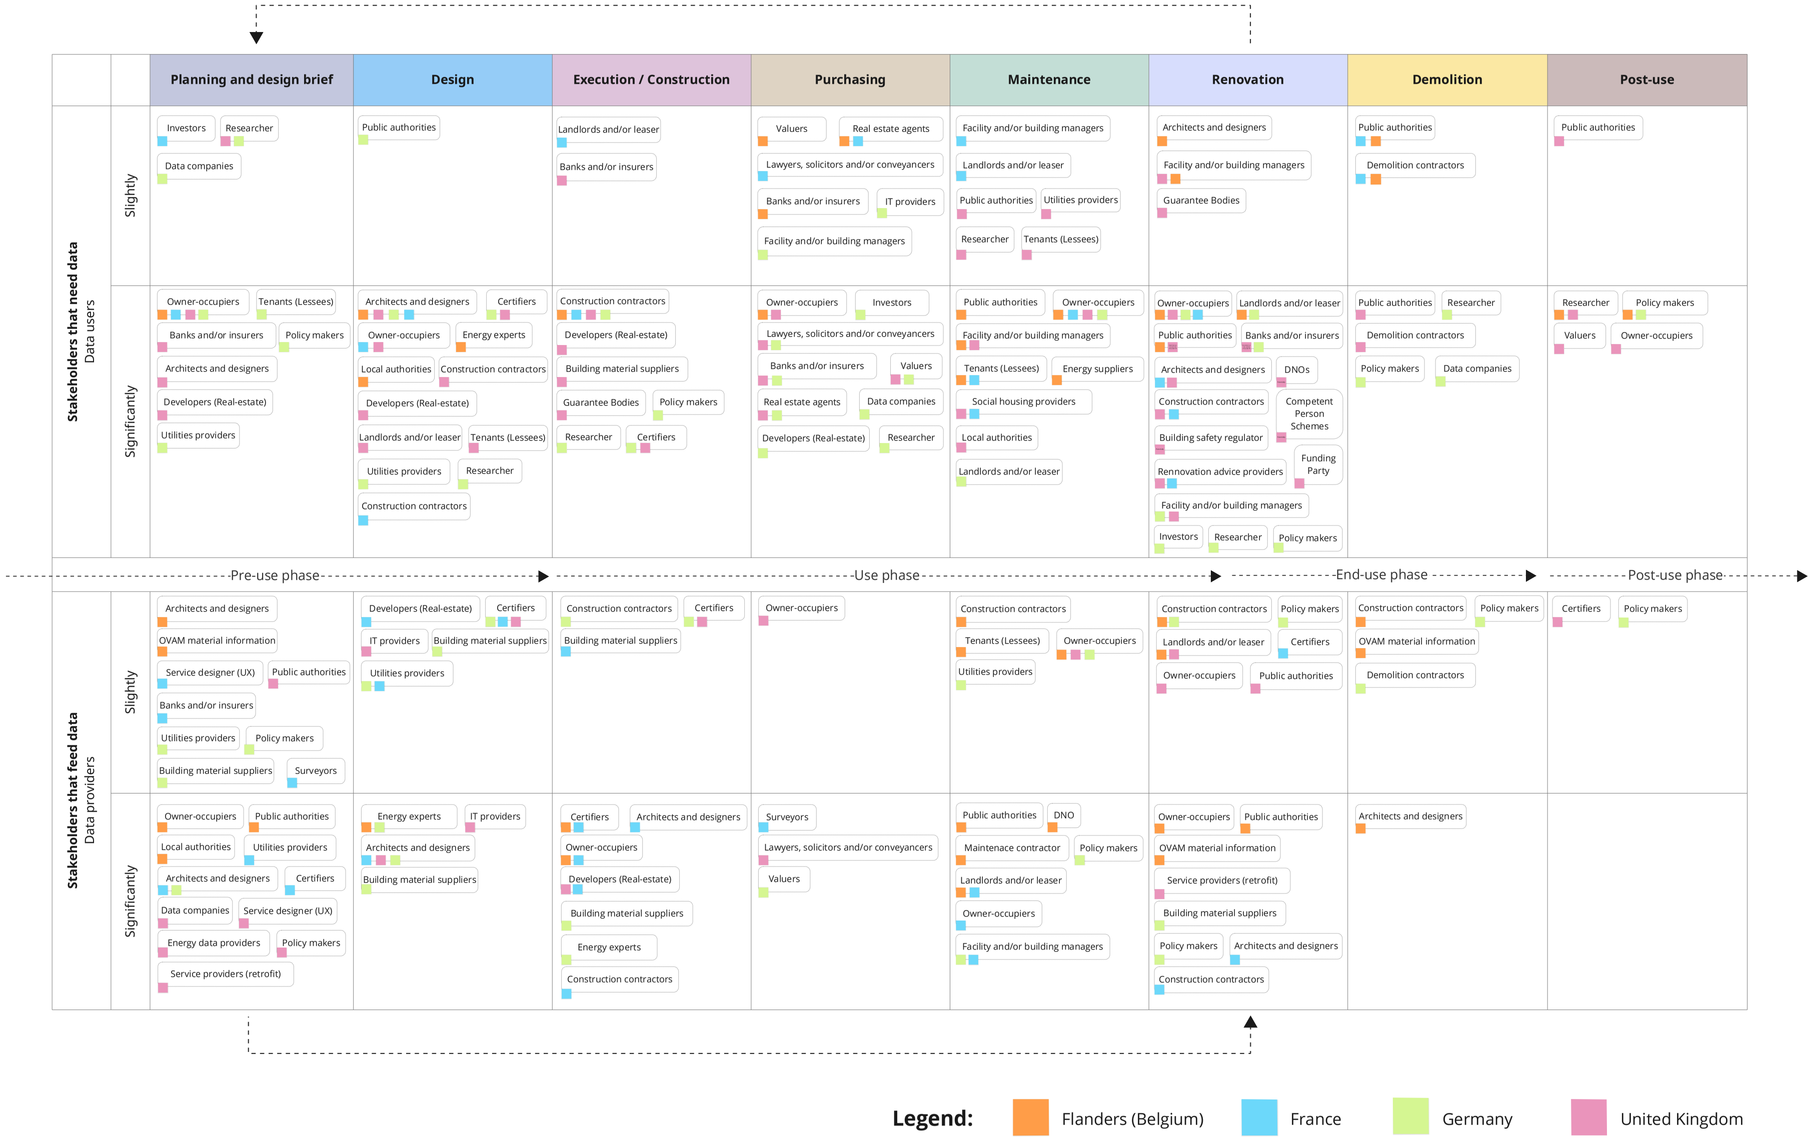

Figure 4: Combined findings of the stakeholder mapping with key stakeholders in the four regions studied, validated with DBL experts (Original work created for Demo-BLog, 2023)

consensus established will then positively open opportunities to further develop a centralized data collection method, a holistic quality scheme for the data collected, as well as the interoperability of the DBL that provides a secured platform for data sharing.

Conclusions

This paper discusses the challenge of stakeholder understanding in the context of digital building logbooks and calls for a wider discourse around the DBL for the cross-sectoral involvement in data collection and sharing. This is a crucial and challenging topic because the DBL and the EU policies around it are still under development. Previous studies indicated that a lifecycle approach to identifying DBL stakeholders is key, but the regional context must likewise be adequately anticipated to yield improved stakeholder engagement.

The findings of this paper indicate that the existing European approaches to DBL stakeholder mapping require a more critical approach. This paper therefore proposes a more comprehensive methodology which involves co-creation between stakeholders of various domains across the construction market value chain and a mapping matrix to visually represent the DBL stakeholder ecosystem that is unique to specific contexts. A key takeaway from this exercise is to place emphasis on the fact that the engagement of the stakeholder to the DBL is two-way, and stakeholders should be viewed as both data users and providers. This additional step helps provide an indication to the overlaps in the inflow and outflow of DBL data among stakeholders, therefore demonstrating the relevance of building data for all identified stakeholders.

Acknowledgments

This research has received funding from the European Union's Horizon Europe research and innovation programme, under the Demo-BLog project (Grant agreement ID: 101091749).

ACQUIRING DIGITAL COMPETENCES FOR CONSTRUCTION PROJECT MANAGEMENT

Zoran Pučko[1], and Nataša Šuman[1]
[1] Faculty of Civil Engineering, Transportation Engineering and Architecture, University of Maribor, Slovenia

Abstract

The construction industry is currently undergoing a profound transformation in project management, led by the integration of Building Information Modeling (BIM) and Industry 4.0. BIM is central to modern construction project management and is at the heart of this change. Slovenian universities have adapted civil engineering curricula to equip students with essential digital skills. The paper describes in detail the experience in teaching BIM and advanced technologies, and thus describes the objectives of the subject, competences acquired, teaching methods and outcomes. The article emphasizes the importance of cutting-edge training and looks at BIM-based and Industry 4.0 courses. By integrating advanced methods into civil engineering education, graduates will be equipped with the digital skills they need for their future careers.

Introduction

Project management is a scientific discipline that is present in all sectors of the economy. Over the last decade, this field has changed rapidly due to the development of advanced technologies. In the construction industry, however, the situation is unfortunately not yet as advanced in terms of the introduction of digitalization (Manyika et al., 2015). Therefore, current efforts are focused on research and examples of best practice, emphasizing a responsible and lifelong approach to the planning and execution of construction projects. At the forefront of these efforts is the implementation of advanced technologies and methods (Xavier and Jacob, 2018). A major challenge is the transformation of traditional business models, shifting from material-centric to information- and digital-centric products, data-driven approaches and intellectual business models (Klinc and Turk, 2019). In general, this means the digitalization of business in the construction sector.

The introduction of Industry 4.0 principles, technologies and methods is enabling transformative advances in the construction industry today. To close the digitalization gap and drive the construction industry forward, it must keep pace with the trends of Industry 4.0 (Klinc and Turk, 2019). The latest research findings highlight trends such as Building Information Modeling (BIM), robotics, project management, advanced materials, offsite construction, occupational safety, monitoring, green building, 3D printing and networked construction sites ("Top 10 Industry 4.0 Trends in 2024 | StartUs Insights," n.d.). These innovations are recognized in both academic and professional circles (Hasan and Sacks, 2021).

The construction sector faces numerous challenges in the digital transformation of management processes. Modern and advanced technologies are gradually being integrated into the entire project life cycle, from planning to execution and post-occupancy. It is crucial that future and current engineers acquire digital skills.

Due to the rapid adoption of BIM, many construction management (CM) and civil engineering programs have added BIM courses to the curriculum or are integrating BIM topics into various courses. According to 2013 data, 54% of construction programs had included BIM courses in their curricula, and 52% of BIM materials were embedded in traditional courses (Wu and Issa, 2014). In the USA, for example, in 2022/23 there are almost 120 universities that are fully accredited and offer degree programs that offer BIM courses as part of the curriculum (Morganti et al., 2023).

Studies dealing with the use of BIM in higher education (Wang et al., 2020) provide a comprehensive review of the current state of BIM education literature and list important journals and conference proceedings in which research on BIM education is published. An analysis of the bibliometric study in the Scopus database was performed (Chihib et al., 2019). For the citations »BIM in University« it was found that the development of publications in the period from 2003 to 2018 is relatively weak compared to BIM worldwide (only 6.4% of articles refer to BIM in universities); the distribution by country and institution shows that the most productive institutions are the USA, the UK and China (46% of all articles).

Many studies that investigated pedagogical strategies for BIM courses show that the two main teaching approaches are team-based learning and project-based learning, for ACE students (Anderson et al., 2020; Jin et al., 2018; Olowa et al., 2022) and for CEM students (Wang et al., 2022; Zhang et al., 2018). Some studies also propose the T-shaped model as a concept for BIM education (Partl et al., 2023).

Two Slovenian faculties that train civil engineers have also recognized the importance of incorporating modern content into the study process and have successfully integrated it by active learning methods (Lassen et al., 2018).

At the Faculty of Civil Engineering, Transportation Engineering, and Architecture (FGPA), University of Maribor ("UM FGPA-a. 2023," n.d.), six undergraduate programs, four postgraduate programs and three doctoral programs are offered in the field of the built environment. The undergraduate and postgraduate programs in civil engineering and industrial engineering, which are crucial for the development of the construction sector, are gradually introducing the principles of BIM approach and Industry 4.0. In this, introduction of Industry 4.0 methods is particularly important for the business and project management aspects of construction projects.

At the Faculty of Civil Engineering and Geodesy of the University of Ljubljana, BIM-related content has been part of the study process since 2008 (Šuman et al., 2023). After 2010, the first courses dealing exclusively with modelling and processes within the BIM approach were accredited. The faculty incorporates the topics of digitization and automation into various courses in the different degree programs. Teaching is implemented with integrated problem-based learning (Computer Integrated Construction degree course, 2nd degree) and a workshop approach, which is primarily used in the undergraduate degree courses. Since the 2019/20, the faculty has also been introducing the international Master's degree course BIM A+ (BIM A+, n.d.).

This paper aims to provide an overview of the formal and nonformal acquisition of digital competences in the field of construction management at the FGPA of the University of Maribor. It describes how students acquire digital competences during the learning process, especially in subjects based on the BIM approach and Construction 4.0 technologies. Informal methods for acquiring digital skills are also outlined. The paper concludes with insights into lifelong learning, including a brief description of the buildingSMART Professional Certification Program ("buildingSMART Professional Certification," n.d.) and the presentation of the Platform 5.0 project as part of the Recovery and Resilience Plan (RRP) ("University of Maribor, Pilotni projekti NOO - UM.si," n.d.), which aims to train workers in the field of digitalization and acquire micro-certificates. In this paper, experiences from teaching digital skills acquisition in construction management are shared with the international community and discussions and suggestions for improvement are encouraged.

Formal acquisition of digital competences through the study process

At the FGPA of the University of Maribor, the importance of introducing methods and technologies for digitalization and automation was already recognized in the 1990s, initially within the framework of the Chair of Construction Informatics. With the development of ICT methods and applications, the importance of their use expanded to other areas within the AEC. Significant benefits were recognised in construction management, which led to the integration of digitalization content into the courses offered by the Chair of Construction Management, Technology and Economics. These topics have been gradually introduced over the last 10 years and are taught by competent teachers who keep up to date with the latest trends and research findings. Digitalization is integrated in most professional subjects and in all elective subjects of the 3rd doctoral level.

Since the 2015/16 academic year, the FGPA UM has been offering a BIM (Building Information Modeling) subject at 2nd level. This subject introduces the general concept of BIM, its role and technologies. Specifically for the area of construction management, methods and tools of digitization are used as a basis for construction processes in further courses at the Chair of Construction Management, Technology and Economics e.g. Project management in construction, which is carried out in final year master students with a background in civil and industrial engineering. In addition to BIM-based content, topics relating to Industry 4.0 methods and technologies have increasingly been covered in recent years. Therefore, in the past two years, the chair offers electives such as Computer modeling of construction objects in the 1st level of study as well as BIM approach in operational construction in the 2nd level. In addition, most of the chair's courses cover topics related to digitization and automation, for example in Safety at construction work, Spatial arrangement and advance planning, Maintenance and rehabilitation of structures and Rehabilitation of civil engineering structures. Figure 1 shows the scheme of courses and degrees related to BIM and Industry 4.0 at FGPA UM. All courses, with the exception of the general BIM course, which is a stand-alone course, benefit from the approach of implementing BIM into existing courses (Ghanem, 2022) and include basic and advanced BIM applications. Electives are labelled (e) and courses in the module are labelled (m).

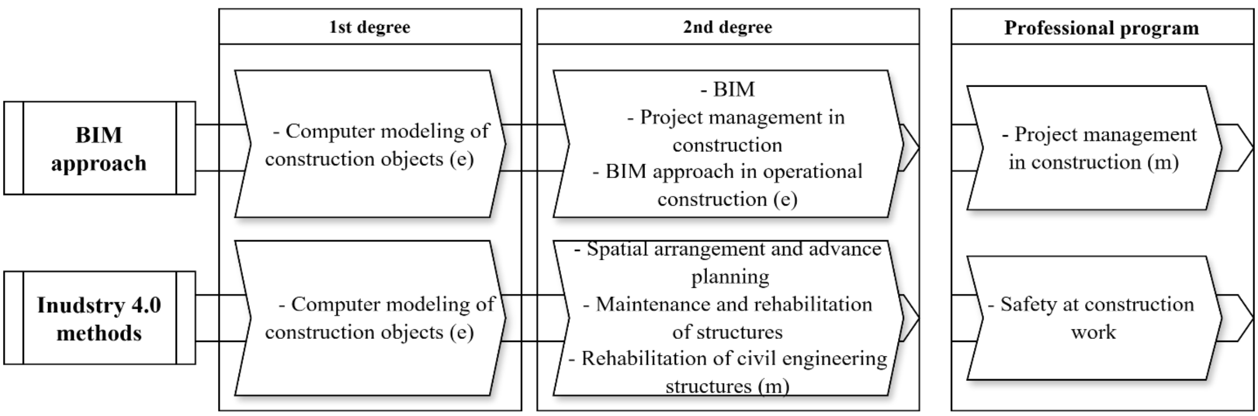

Figure 1: Scheme of courses and degrees with topics on BIM and Industry 4.0

Members of the chair also supervise student theses on digitalization topics. Through courses and theses, students acquire advanced digital skills, roughly divided into a) BIM-supported learning processes, b) learning processes with Industry 4.0 methods and technologies and c) theses on digitization in construction. The following sections present the FGPA's efforts to integrate BIM-based and Industry 4.0 topics into the curricula of the 1st and 2nd degree programs.

Integrating the BIM-based approach

The integration of the BIM-based approach into the study process has been underway at FGPA for many years. The first working example of BIM was introduced specifically for the management of construction projects in the 2015/16 academic year. These concepts were integrated into the subject Project management in construction in the 2nd degree program, which is offered jointly in two study programs: Civil Engineering and Industrial Engineering. This year, a 4D and 5D BIM model for a garage building in Skopje was created as a working example. In following years, the students expanded their knowledge by creating 4D and 5D BIM models for various building construction projects, including a school sports hall, a single-family house with associated infrastructure, a commercial office building, a two-family house, an apartment building, a single-family house with outdoor area and a high-bay warehouse. Since the 2019/20, this approach has also been used at the 1st degree professional study program Civil Engineering, subject of the Operational construction module.

Project work with students on the Project management in construction course follows a structured procedure: students first familiarize themselves with a basic 3D BIM model for a real object and learn about the importance of 3D model information and its application. They then extend the basic model to 4D (construction schedule) and 5D (construction costs) BIM models. Theoretical knowledge about higher BIM dimension levels, i.e. 4D, 5D and 6D BIM models, is taught in lectures. The project work itself is carried out through tutorials and computer-based tasks, with groups of up to three students working together. Selected software tools, including the modules of the Trimble Vico Office™ software (“Vico Office,” n.d.), the local tool 4BUILD for cost estimation and MS Project (“Project Management Software | Microsoft Project,” n.d.) for scheduling, are used to create 4D and 5D BIM models. A more detailed description and a diagram of the BIM creation process during the study at the FGPA of the University of Maribor can be found in the articles in (Pučko et al., 2019; Pučko and Šuman, 2024).

In the 2022/2023 academic year, the students created a highly detailed BIM model for a single-family house that encompasses both the 4D and 5D dimensions. The input data came from a conceptual design that was developed using Allplan BIM software. The original 3D BIM model was previously created and served as an input model for working with students. Figure 2 shows the 3D BIM model of the single-family house and illustrates the level of detail achieved in this comprehensive BIM model.

Figure 2: 3D BIM model of a single-family house

The Vico Office software was used to create the 4D and 5D BIM models, which does not allow direct import from the Allplan program. This led to particular challenges when using the basic 3D BIM model, which had to be converted via the IFC format. Despite these challenges, this was an additional learning opportunity for the students to effectively customize the 3D BIM model and familiarize themselves with the IFC format. For this reason, the subsequent detailed work focused exclusively on the basement of the building.

The creation of 4D and 5D BIM models was carried out in groups of two students each, so that a total of six groups were formed. Each group was assigned a specific set of building elements, which are listed in Table 1. First, the groups thoroughly analyzed the elements assigned to them, taking into account dimensions, material, technology, quantity, etc. They collected input data important for estimating unit costs and scheduling, including market prices for materials, equipment and machinery, as well as average wages and standards for labor.

A 5D BIM model was then created using the Cost Planner module. This software offers a significant advantage as it enables the direct and bidirectional linking of cost information with the 3D BIM model elements. This means that every change to the geometry of the 3D BIM model automatically updates the associated costs. The activities and their sequence were then defined as the basis for planning the construction work.

The software facilitates time analysis by creating a 4D BIM model in the Task Manager module. When analysing time, the elements of the 3D BIM model are directly linked to the activities in the schedule. This approach takes into account the links between the activities and the allocated resources and provides a comprehensive understanding of the time aspects of the project.

Table 1: Students group number, assigned project tasks and visualization of building elements

#	The topic of the project task	Visualization (set in Vico Office)

1	001 Reinforced concrete point foundations 010 Reinforced concrete stair foundation	2	007 Drywall walls 017 Plastering of reinforced concrete basement walls	3	008 Reinforced concrete basement walls	4	009 Reinforced concrete columns-ties 015 Facade	5	004 Reinforced concrete base plate	6	003 Gravel filling 005 Waterproofing 006 Thermal insulation XPS 016 Facade waterproofing	
In December 2023, a final presentation of the groups' project work took place at the faculty. Each group presented the 4D and 5D BIMs they had created (Figure 3). At the end, the overall result for the execution of the basement was also presented to the students as a comprehensive 3D, 4D and 5D BIM model (Figure 4). A simulation of the construction process was also created by the course teacher. This representation of common 4D and 5D BIM models gives students an insight into the overall cost estimate and schedule.

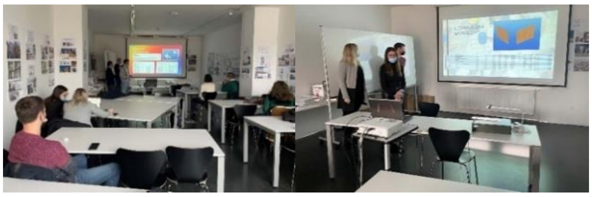

Figure 3: Final presentation of project work

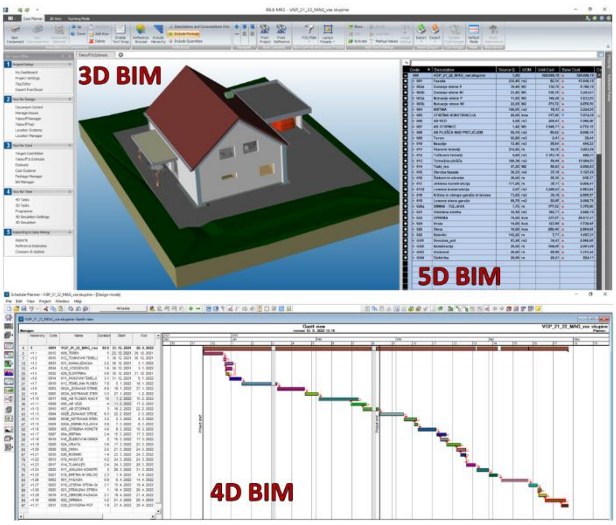

Figure 4: Comprehensive 3D, 4D and 5D BIM model

Integrating methods and technologies of Construction 4.0

Although there is no uniform definition for Construction 4.0, as can be seen from the literature review (Forcael et al., 2020; Jazzar et al., 2020; Perrier et al., 2020), it can be summarized that there is a consensus that the introduction of Construction 4.0 will not only change the construction process, but also the organizational and project structures, transforming the dispersed construction industry into an integrated industry. Individual disruptive technologies that are increasingly being used in the construction industry stand out. In recent years, students have become familiar with the theoretical starting points of Construction 4.0 and acquired individual knowledge and practical skills. For example, in numerous subjects, both in the 1st and 2nd levels of study, digital content is obtained using the technology of data acquisition of the environment using a 3D laser scanner. This technology is used in the following subjects Safety at construction work (1st degree), Spatial arrangement and advance planning (2nd degree), and Maintenance and rehabilitation of structures (2nd degree). The use of a 3D laser scanner is possible for a variety of purposes, such as capturing the as-built condition of the environment, ensuring site safety, determining work progress and creating a 4D as-built BIM model, etc. As part of the subjects listed, students are shown how to use a 3D laser scanner and the method of collecting point cloud data. Figure 5 shows the point cloud data acquired by the students for the selected site as part of the Spatial arrangement and advanced planning course on 2nd degree of study program Industrial Engineering.

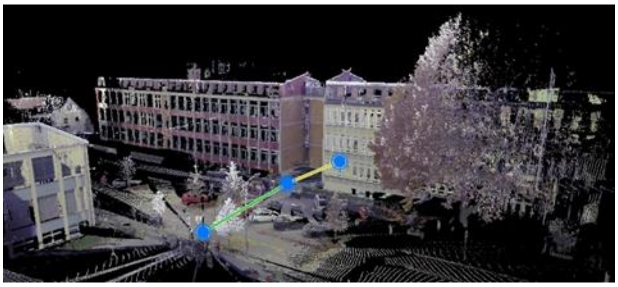

Figure 5: Acquired point cloud data by the students

Students also gain from the modern digital content of Industry 4.0 through advanced augmented reality technologies. With these methods, they acquire knowledge and skills to connect a real environment with digital elements that enable a 1:1 visualization of the built environment. This technology is still relatively new in the construction sector and therefore only a few applications can currently be demonstrated in practice. However, we believe that this technology has great potential and it is expected that further innovations will be developed in the coming years. Figure 6 shows an example of the use of advanced mixed reality in Spatial arrangement and advanced planning course on 2nd degree of study program Industrial Engineering in the 2022/23 academic year.

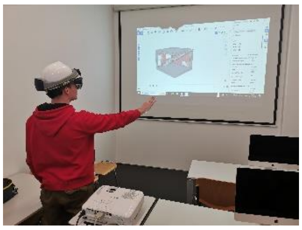

Figure 6: Use of advanced mixed reality during the study process

Nonformal acquisition of digital competences

Many other nonformal learning activities on the topic of digitalization and automation in the construction industry are also carried out at the FGPA. These activities include student participation in various professional events, conferences, trade fairs, excursions, and site visits.

In terms of student participation in various events such as conferences and trade fairs, we would like to highlight a 2-day professional excursion in 2018 with the participation of 50 students at the BIM WORLD Munich Congress (Figure 7-a) (Pučko et al., 2019). In 2023, a visit to the 33rd International Fair for Construction (MEGRA) in Slovenia was organized for students ("Megra 2023," n.d.), where the students took part in an event entitled An educational day in the Slovenian construction industry. Presentations of the latest digital technologies were held at the thematic lectures ("Chamber of Commerce and Industry of Slovenia," n.d.).

In addition, the students took part in an open day in May 2023 at the invitation of the Protim Ržišnik Perc design office. They were introduced to the latest software for working in the BIM environment, as used in the office's design practice (Figure 7-b) ("UM FGPA-b. 2023.," n.d.).

In 2023, various excursions were organised for students with visits to construction sites where the BIM approach was used for detailed design and during construction. We visited the following construction sites with the students, among others Second track Divača-Koper railway line (Figure 7-c) ("UM FGPA-c. 2023.," n.d.) and short visits to construction site Center Rotovž in Maribor (Figure 7-d) ("UM FGPA-d. 2023.," n.d.).

(a)

(b)

(c)

(d)

Figure 7: a) BIM WORLD Munich Congress, b) open day of the project bureau Protim, c) Construction site Second track Divača-Koper railway and d) Construction site Center Rotovž Maribor

All these activities help students to broaden their horizons and gain a closer insight into how modern techniques and methods are applied in the construction process.

Activities of lifelong learning at FGPA

Lifelong learning for working graduates on the topic of acquiring digital competences has been implemented at the FGPA since 2022. This involves running the Fundamentals of BIM course, which is offered under the auspices of the bSI Professional Certification Program ("buildingSMART Professional Certification," n.d.). After completing the course, participants can take an exam to obtain a certificate for basic BIM knowledge, the so-called buildingSMART Professional Certificate, which internationally certifies that professionals are highly qualified and recognisably trained in digital working methods. FGPA is designated as the official training center for the implementation of this program. Civil engineers, architects, electrical engineers and some students (civil engineering and architecture) have successfully completed the course so far.

From July 2022, a pilot project introducing advances digital technologies is also being implemented at the FGPA. The project is being implemented as part of the Recovery and Resilience Plan (RRP) ("University of Maribor, Pilotni projekti NOO - UM.si," n.d.). The University of Maribor is carrying out a total of 23 such pilot projects, which are intended to enable a green and resilient transition to Society 5.0. At the FGPA, the project is called Platforma 5.0 FGPA. The aim of the platform is to identify the knowledge and skills required to promote sustainable development and digitization in study programs over a period of three years. One of the aims of the project is also to create modules for lifelong learning for professionals who will acquire micro-certificates after completing the courses. At the same time, digital technologies for informatization of education will be recognized and implemented, including BIM-based and Industry 4.0 content. Upon completion of the project, the study programs will be aligned with the needs of the economy and society, and students will acquire digital skills and competencies for the green transition and digitization in addition to the competencies dictated by the labor market.

Lessons learned

Each academic year, FGPA UM conducts a course evaluation survey to evaluate the teacher's grade point average and student workload. In the 2022/23 academic year, teachers grades for courses with a BIM approach and Industry 4.0 content were above average at 1.66 (grade range from -2.00 to +2.00). In general, no 1-year or 2-year deviations were identified in terms of student workload. The deviation was only found in the subject Computer modeling of construction objects (+-20%), where students felt that there were too many lectures and tutorials, but students had more independent work. The course was run for the first time this academic year and the results of the survey provide a good basis for the direction of the work in the future.

During several years of running courses on the integration of BIM and two years of implementing Industry 4.0 methods in existing courses, we have come to the following conclusions:

- Working with the BIM approach enables students to better understand the entire construction process, in particular the specific integration and upgrade of 4D BIM (time planning techniques) and 5D BIM (cost estimation approaches)
- The use of interdisciplinary teamwork helps students to develop their collaboration and problem-solving skills and increase student engagement to achieve better results.
- Teachers who actively implement project- and team-based learning together with their students generally ensure a higher quality of teaching.

Based on the knowledge gained, organizational and structural changes are planned:

- A new computer classroom should be set up for practical exercises, equipped with high-quality computers (for conducting BIM courses, modeling and simulation) and the necessary equipment for 3D printing, VR/AR/MR equipment and robots in the construction industry (Industry 4.0).
- As part of the renovation of study programs at the 1st level, a stand-alone BIM course should be introduced to teach the BIM concept and specific modeling skills. The course could replace the current CAD course or be offered as an elective.
- BIM software training should be offered to students and teachers, preferably in collaboration with local industry, to give students hands-on experience.
- Collaboration between teachers on BIM and Industry 4.0 courses should be encouraged and their education made possible.

Conclusions

Despite the rapid development of Industry 4.0 methods, the construction industry is lagging far behind other sectors in terms of digitalization and automation. Project management in the construction industry has changed significantly with the introduction of modern tools, which requires rapid adaptation of learning processes and the integration of BIM and Industry 4.0 into university curricula. This paper outlines the approach taken at the FGPA of the University of Maribor to teach formal and acquiring nonformal digital competences, with a focus on BIM and advanced technologies of Construction 4.0. The emphasis is on providing a comprehensive understanding of BIM principles, mastery of the software and practical application through project work. Nonformal learning, including conferences, trades, and site visits, plays a crucial role in students' education, especially in the context of the accelerating global digital transformation. The implementation of lifelong learning at FGPA through courses such as Fundamentals of BIM and the FGPA Platform 5.0 project ensures continuous education and professional buildingSMART certification for students and professionals alike.

Acknowledgments

The project is co-financed by the Republic of Slovenia, Ministry of Higher Education, Science and Innovation, and the European Union – NextGenerationEU. The project is implemented in accordance with the Smart, Sustainable and Inclusive Growth development area, Strengthening of Competencies component, especially digital competencies and those required by new professions and the green transition (C3 K5), for the investment measure Investment F. Implementation of pilot projects, the results of which will serve as a basis for the preparation of grounds for the reform of higher education for a green and resilient transition to Society 5.0: the project Pilot projects for the Reform of Higher Education for a Green and Resilient Transition.

ELECTRONIC PERFORMANCE MONITORING AT THE WORKPLACE: A SURVEY TO DIAGNOSE ENGINEER'S AWARENESS

Diego Calvetti[1], Miguel Chichorro Gonçalves[1], Pedro Mêda[1], and Hipólito de Sousa[1]
[1]CONSTRUCT/Gequaltec, University of Porto, Porto, Portugal

Abstract

The electronic performance monitoring (EPM) of human resources using new technologies increases current control methods while introducing ethics and moral concerns. In chasing EPM deployments, a survey was conducted to diagnose the perception of workers and students. The engineers were elected as core participants in EPM due to their knowledge of both the technology and the field of application. Surprisingly, 69% of the 261 respondents were unaware of the topic. Results indicate a 56% acceptance level (95% confidence level and 6.3% error). The research points out the most accepted and rejected aspects of EPM, illustrating scenarios and alternatives for implementation.

Introduction

The industry has been applying numerous innovations in electronic devices and wearables to monitor workers' performance. Institutions seek to use electronic monitoring of human resources to increase their financial results (Alder, 2001). Electronic Performance Monitoring is about the use of hardware, software, and techniques to access and evaluate human resources job performance (Alder & Tompkins, 1997; Lund, 1992; Oz et al., 1999; Panina & Aiello, 2005). The great challenge to electronic monitoring is related to trust and security in sharing data between workers and employers (Calvetti et al., 2020; Calvetti, Mêda, et al., 2021; European Commission. Directorate General for Research and Innovation., 2021; Kelly, 2018; *Use of Wearables in the Workplace Is Halted by Lack of Trust – PwC Research - Press Room*, n.d.). Perceiving the people's reaction to monitoring is a fundamental part of achieving success in implementing technological innovation projects (Bhave, 2013; Holland et al., 2015; Panina & Aiello, 2005; Stanton & Julian, 2002). Industrial sectors, such as construction, whose financial result is strongly linked to the physical performance of human resources, seek to improve their control tools in safety, health, productivity and quality of services (Calvetti et al., 2022; Calvetti, Goncalves, et al., 2021). A worker away from work due to accidents or work-related illnesses has a negative impact on the performance of companies. Work activities with a great need for human physical effort and little repeatability have significant variability in productivity rates and demand numerous processes to control the quality of services.

In addition to current control methods such as using computers (email, internet, etc.), access control by badges, and monitoring the use of equipment and machines. Electronic monitoring advances in analysing location, movements, gestures, and the physiological state of workers. Tracking the location of each worker in near real-time provides, in addition to the analysis of their productive occupation, the diagnosis of permanence in areas with safety hazards and routes with the risk of being run over by machinery and equipment (Bangaru, Wang, & Aghazadeh, 2020; Duan et al., 2022; Igwe et al., 2022; Jung & Chi, 2020; Ryu et al., 2020). The detailed assessment of workers' movements and gestures allows for a precise ergonometric analysis, which helps analyse occupational health, safety and productivity (Bangaru, Wang, Zhou, et al., 2020; Yang et al., 2019; Zhang et al., 2019). Collecting data regarding the workers' physical state (cerebral electrical activity, temperature, pressure, heart rate, etc.) makes it possible to assess the physiological state (tiredness, fatigue, stress, tension, etc.), which also allows for the assessment of performance in health, safety and productivity (Ahn et al., 2019; Choi et al., 2019; Costa et al., 2019; Jebelli et al., 2018; Wang et al., 2019).

However, current technological advances allow for a new and vast field of investigation regarding human resources performance. Nevertheless, legal paradigms and restrictions regarding electronic monitoring must be confronted. Realising workers' reactions to electronic monitoring is a crucial element in achieving successful technological innovations in the workplace (Ahn et al., 2019; Maurice et al., 2019; Ryu et al., 2019; Yan et al., 2018). Because of that, a survey was conducted to understand better peoples' reactions to electronic monitoring at work.

Survey sample

A total of 8914 people received the questionnaire, which 8478 - Students of the Faculty of Engineering of the University of Porto (FEUP), 16 – Professors of FEUP, and 420 - People from the authors' network (mainly from LinkedIn social network). A total of 261 people answered the questionnaire, which determined a response rate of 2.93%. Based on the population (8478) and sample (261), within a confidence level of

95% (P = 0.5), the accuracy of the responses reached an index of ± 6.3% (Dupont et al., 2017).
The collected data were tabulated in MS Excel for analysis and graphical development. Furthermore, the IBM SPSS system was used for the univariate and multivariate statistical analysis. Finally, the results were discussed by comparing similar research conducted by the insurance company AIG (American International Group, Inc.) in nine countries with 400 employees and 250 entrepreneurs in the year 2016 (Mike Abbott, 2017).

Young Portuguese students gave the most significant number of answers from Engineering in Information Technology and Computers, Civil Engineering, Mechanics, Metallurgy and Materials Engineering. Concerning the education level, 67% of respondents are students, and 13% study and work; in effect, 80% of the sample is currently a student. It is worth noting that the vast majority of these, 58%, attend the integrated master's degree, followed by 16% to develop degrees, 15% for doctorates and 10% for master's degrees.

Regarding the field of activity (academic/professional), it was identified that most of the respondents are from technology and computing fields, with 43%, followed by 24% of civil engineering, mechanics, metallurgical, and materials.

As for gender, there was 64% of males, 35% of females, and 1% of respondents chose not to be identified by a specific gender. Moreover, as seen previously, the more representative public sampled are students who are predominantly young, with 34% between 16 and 21 years old and 33% between 22 and 25 years old. However, the sample represents the perception of future engineers who are going to enter the labour market in the coming years. Finally, 87% of the respondents live in Portugal, and 10% are Brazilian residents, among other countries with 3%.

Results and discussions

In order to conduct the respondents for real situations about the application of electronic performance monitoring at work, fourteen situational questions were applied. Moreover, two questions sat the respondents in the position of the employer and twelve as workers. Besides, interviewees' personal view-positioning was observed in two questions about believing that monitoring their own work is essential to improve performance and if the government should regulate EPM. Finally, to identify whether the respondents already had any knowledge about the EPM subject, one question was asked. The results of these seventeen questions are presented and discussed in the exact order developed in the survey.
Questions 1 and 3-8 were the types of yes/no answers with room for alternative/free opinions. Question 2 presents different options to agree/disagree as well as with room to write a distinguished option.

Question 1: Do you believe that monitoring the progress of activities developed during the workday is important for improving your performance?
Result: Yes 209 (80%), No 52 (20%). It is noticed that the great majority understand that monitoring is a relevant tool for the improvement of their own performance.
Question 2: By placing yourself in the position of EMPLOYER, you would want to use technological innovations to monitor. Alternatives: The safety of workers; The health of workers; The productivity of workers; The quality of services performed by workers; Other (field for text insertion).
Results: As shown in Figure 1, it is perceived that respondents would be more interested in monitoring order: Safety of workers 200 (77%); The productivity of workers 185 (71%); The quality of services performed by employees 182 (70%); Workers' health 155 (59%); Do not monitor 5 (2%). The values in safety, productivity, and quality are close, and health monitoring is significantly below, with still fewer responses contrary to any form of monitoring. Compared to the survey carried out by AIG (Mike Abbott, 2017), it is observed that the population responding has higher interest levels, as for security (77%) compared to (59% AIG), productivity (71%) versus (55% AIG), and health (59%) versus (55% AIG).

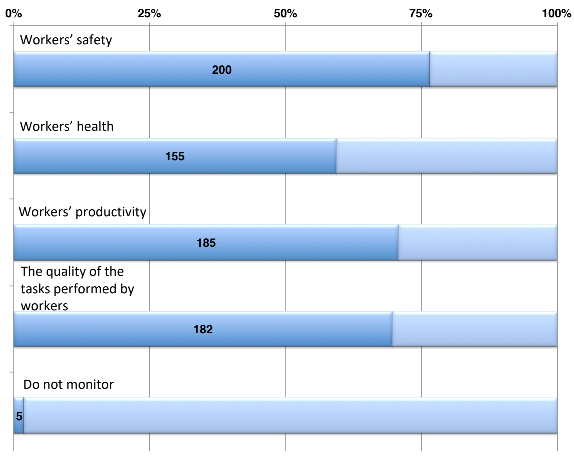

Figure 1: Subjects of interest to be monitored

Question 3: By placing yourself in the position of EMPLOYER, do you believe that in the case of applying the monitoring, you should share this data collected with the employees?
Result: No (this information must be exclusive to the company) 47 (18%), Yes (I must allow workers access to information) 214 (82%). It is noticed that in the vast majority, people understand it necessary to share the data collected with the workers. The study conducted by AIG (Mike Abbott, 2017), evaluated the intention to share data of employees and employers, where per country:

- Japan - employees (80%), employers (65%)

- United States of America - employees (75%), employers (65%)
- Australia - employees (74%), employers (65%)
- Singapore - employees (76%), employers (69%)
- United Kingdom - employees (74%), employers (68%)
- Italy - employees (87%), employers (85%)
- Germany - employees (70%), employers (70%)
- China - employees (93%), employers (97%)
- France - employees (66%), employers (76%)

There is an alignment of the sample surveyed regarding the sharing of data, mainly countries with higher indexes of intention to share, such as Japan and Italy.

Question 4: Do you believe that the GOVERNMENT should regulate electronic monitoring at work?

Result: Yes, 141 (54%), No 107 (41%), Depends on the level of monitoring 4 (2%), I have no opinion 4 (2%), Other responses 5 (2%). Compared with the results of AIG's survey (Mike Abbott, 2017), which indicated that 89% of employers and 87% of employees understand that there should be legal regulation of monitoring (Mike Abbott, 2017), the rate of only 54% seems low. Because the survey sample is predominantly of young students (still out of the job market), two hypotheses can be assumed for such a low value. Firstly, students still do not know/fear the possible persuasive use of EPM. Secondly, young people accept electronic monitoring more naturally than older generations (employees and employers).

Question 5: By placing yourself in the position of EMPLOYEE, would you allow the mapping of your location in real-time by the employer?

Result: Yes, 111 (43%), No 150 (57%). At this point in the survey, respondents are confronted with more frontal questions about electronic monitoring methods at work. Of effect, it can perceive some greater reactivity from the respondents regarding EPM, in this specific case of allowing the mapping location in real-time.

Question 6: By placing yourself in the position of EMPLOYEE, would you allow the mapping of your movements/motions (trunk, legs, arms, and hands) by the employer?

Result: Yes, 86 (33%), No 175 (67%). Within the same analysis performed previously, and specifically regarding the monitoring of the movements and gestures, the respondents' significant reactivity was identified. This sentiment is aligned, for example, with the journalistic material published on CNN Tech, regarding the controversial patent application by the Amazon company with the intention of monitoring the workers' arms motions (Kelly, 2018).

Question 7: By placing yourself in the position of EMPLOYEE, would you allow the mapping of your physical conditions (electrical activity of the brain, temperature, pressure, heart rate, etc.) by the employer?

Result: Yes, 138 (53%), No 123 (47%). Given the two previous answers, the monitoring of physical conditions reached a higher rate of acceptance. One possible hypothesis is that the respondents connect the monitoring of physical conditions to health issues, and in the opposite, the two before productivity issues. However, it should be noted that monitoring these physiological aspects could undoubtedly be used to assess productivity.

Question 8: By placing yourself in the position of EMPLOYEE, would you feel safe sharing the data collected by wearable electronic devices with the employer?

Result: Yes, 143 (55%), No 118 (45%). It is identified that more than half of the respondents would trust their data to the employer. However, the survey carried out by AIG regarding the employees' intention to share the data indicates higher indexes of the order of 66% to 93% (Mike Abbott, 2017).

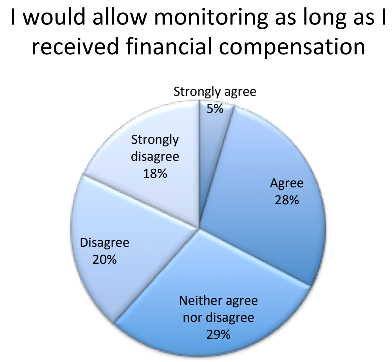
Questions 9, 10, and 11 requested a situational opinion, as employees, if they were prone to allow the monitoring to receive some rewards. Meanwhile, questions 12 and 13 try to perceive awareness about safety and health in the workplace. Smartphone data collection/analysis is a current issue. Questions 14 and 15 asked if they would share data from their own device and in case of that device was from the company. Question 16 puts respondents against the wall, asking if their job depends on the acceptance of EPM if they would allow it. Finally, in the last question, 17 asked if they knew, before that survey, about those EPM methods at the workplace.

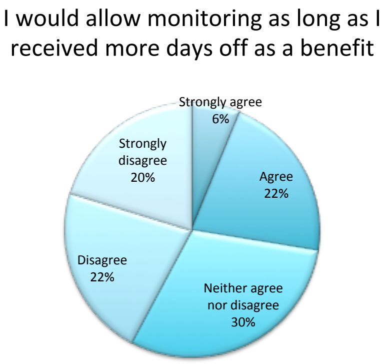
Question 9: Regarding the monitoring by means of electronic devices and wearables, by placing yourself in the position of EMPLOYEE in these situations: "I would allow monitoring as long as I received financial compensation.".

Question 10: Regarding the monitoring by means of electronic devices and wearables, by placing yourself in the position of EMPLOYEE in these situations: "I would allow monitoring as long as I received more days off as a benefit.".

Question 11: Regarding the monitoring by means of electronic devices and wearables, by placing yourself in the position of EMPLOYEE in these situations: "I would allow monitoring as long as this would help my hierarchical progression in the company.".

It is noticed that the respondents value more the professional career concerning other rewards such as financial benefits and days off. The hypothesis that can be inferred is that the young public of the sample aims to enter the job market and to have professional success, not yet realise the relevance of the financial benefits and times of rest; see Figure 2, where it is highlighted: 33% agree, or strongly agree to allow monitoring through financial compensation; 28% agree, or strongly agree to allow monitoring by receiving more days off; 44% agree, or strongly agree to allow monitoring through a hierarchical progression in the company.





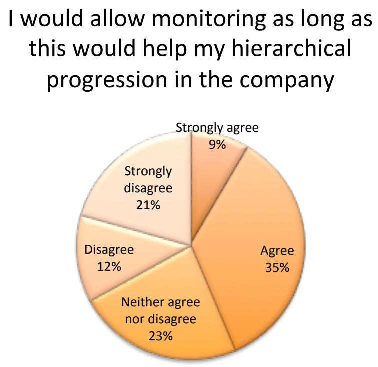


Figure 2: Situation of enabling monitoring in exchange for benefits

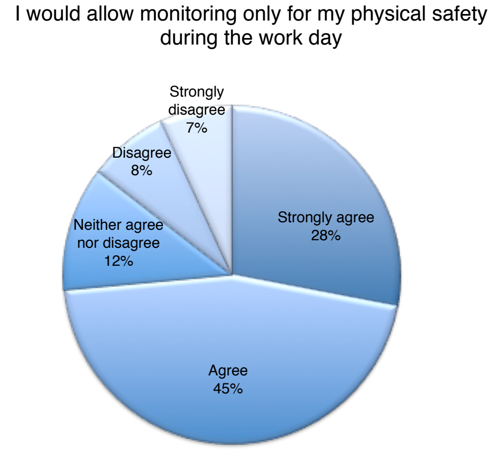
Question 12: Regarding the monitoring by means of electronic devices and wearables, by placing yourself in the position of EMPLOYEE in these situations: "I would allow monitoring only for my physical safety during the workday.”.

Question 13: Regarding the monitoring by means of electronic devices and wearables, by placing yourself in the position of EMPLOYEE in these situations: "I would allow monitoring only in the concern to improve my physical health during the workday.".

Figure 3 presents the results. It can be identified that the respondents have great motivation to accept monitoring for their own safety and health, where 74% agree or strongly agree to allow monitoring in the pursuit of improving physical safety during the workday; 68% agree or strongly agree to allow monitoring in the quest to improve physical health during the workday.



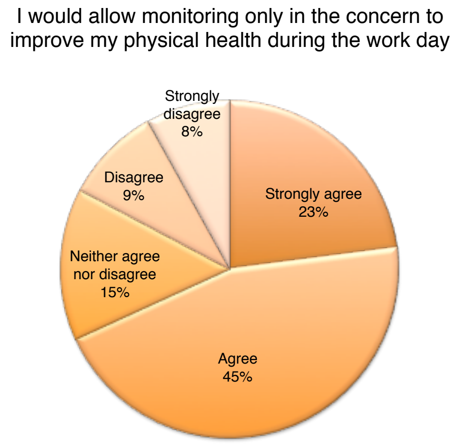


Figure 3: Situation of allowing monitoring for greater safety and health during the workday

Question 14: Regarding the monitoring by means of electronic devices and wearables, by placing yourself in the position of EMPLOYEE in these situations: "I would allow monitoring of data from my own smartphone.".

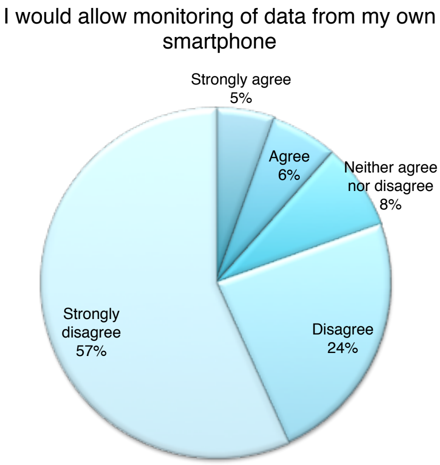
Question 15: Regarding the monitoring by means of electronic devices and wearables, by placing yourself in the position of EMPLOYEE in these situations: "I would only allow monitoring data from a smartphone provided by the company.".

Figure 4 presents the results. It is noticed that the respondents strongly reject the idea of allowing the availability of data on their own smartphones. However, when the hypothesis of the smartphone was provided by the employer, there was a significant tendency of acceptance to share data, where it is highlighted that 11% agree or strongly agree to allow monitoring of data from the smartphone itself; 50% agree, or strongly agree to allow the monitoring of smartphone data provided by the company.

The study carried out by AIG (Mike Abbott, 2017) highlights the favourable position of employees in using a device provided by the employer, by country as forward presented:

- Germany (29%)
- Japan (36%)
- United States of America and Australia (38%)
- United Kingdom and France (40%)
- Italy, Singapore and China (56%)

The indices identified in this survey of 50% are above the position of several countries, being close to Italy, Singapore, and China (56%), countries with more favourable indexes.



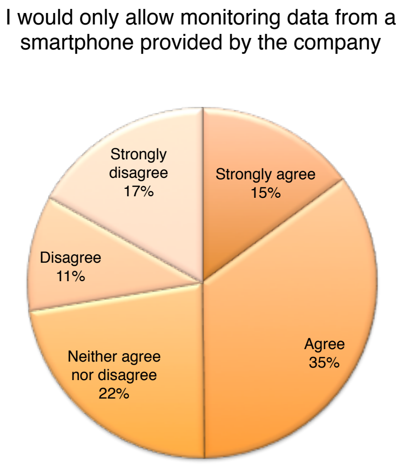


Figure 4: Situation of allowing monitoring for greater safety and health during the workday

Question 16: Regarding the monitoring by means of electronic devices and wearables, by placing yourself in the position of EMPLOYEE in these situations: "I would never allow monitoring, even if that would be a prerogative to get the job.".

It should be noted that 55% disagree or strongly disagree with the proposed statement, which indicates that these respondents in the postulated case would accept the monitoring to access/guarantee a job vacancy. Only 14% responded by indicating that they would withdraw from the job if there were the prerogative of monitoring, where the result points out that: Strongly agree (7%); Agree (7%); Neither agree nor disagree (31%); Disagree (28%); Strongly disagree (26%).

Question 17: Have you had contact or knowledge of the use of electronic monitoring systems in the workplace?

Surprisingly, a large part of the respondents (69%) only has known about the subject of electronic monitoring at work through this survey. In practice, only 7% had real-life experience with EPM, and 24% knew some piece of information from some news. Where the options presented were: No. “I did not know the matter.” 180 (69%); Yes. “I've followed or participated in projects of this type.” 19 (7%); Yes. “I had already obtained information on the subject (internet, videos, lectures, etc.).” 62 (24%)

An EPM level of acceptance is possible by quantifying the answers. The questions with answers of type "yes" or "no" were quantified on a binary scale, been by unfavourable added zero (0), and most favourable to the monitoring one (1), where: Question: 1; Yes (1), No (0); Question 3; No (1), Yes (0); Question 4; Yes (0), No (1), Depends on the level of monitoring (0), I have no opinion (0), Other answers (0); Questions 5-8; Yes (1), No (0).

As a criterion for the question of multiple choices (question 2), one value (1) was established for each selected item. Given a value of zero (0) to the indications of not monitoring. In this question, the values have variables from zero (not monitor) to four (selection of all items), where the safety of workers (1), Workers' health (1), The productivity of workers (1), The quality of services performed by workers (1); Do not monitor (0).

For situational questions with five alternatives (questions 9-15), according to the favourable or unfavourable sense of monitoring, the following values were assigned: Strongly agree (1); Agree (0,5); Neither agree nor disagree (0); Disagree (-0.5); Strongly disagree (-1).

Specifically for question 16, which has an otherwise sense of agreement, the values were: Strongly agree (-1); Agree (-0,5); Neither agree nor disagree (0); Disagree (0.5); Strongly disagree (1).

With this, based on the above-detailed quantification, the maximum attainable value (all favourable responses) is “19 values”; in counterpoint, the lowest possible value (all unfavourable responses) is “-8 values”. Based on the responses and values, a value level was determined for each respondent, see Figure 5.

Proportionally, the total spectrum was divided into four quartiles. The first is with an index between 0-25% (Q0), the second between 25-50% (Q25), the third between 50-75% (Q50), and finally, the fourth quartile between 75-100% (Q75).

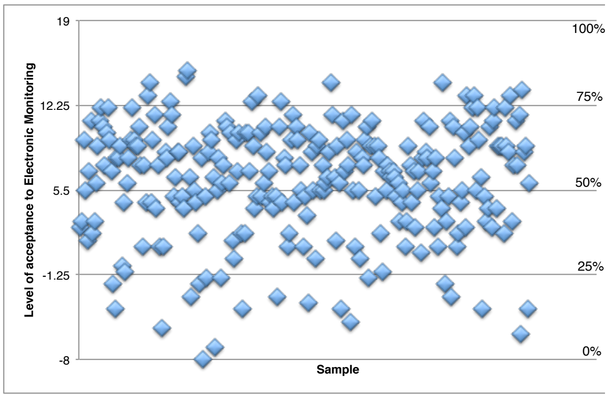

Figure 5: Acceptance level for electronic sample monitoring

It is observed that 60% of the sample (156 respondents) is in the Q50 (between 50-75%) of acceptance to the EPM. In the top quadrant, Q75, with an acceptable level greater than 75%, there are 14 respondents (5%). In this sense, it is highlighted a trend of sixty-five per cent favourable to EPM by these populations under analysis. Within Q25 (25-50%), there are 71 respondents (27%). Furthermore, at the lower end, positions totally contrary to EPM, only 20 respondents (8%) were found.

Employing the SPSS software, the values and histogram graph, see Figure 6, of the total sample were determined statistically. It is observed that the average (6.3180) and the median (7.0000) have approximate values. The kurtosis value (0.3630) is below 0.5, indicating the normality of the distribution. However, the marked asymmetry (-0.7500) and the mode value (9.0000) accept the values' distribution as expected. The value that most represents the population under analysis is the median (7.0000). Other values are Standard deviation (4.4411), Variance (19.7230), Minimum (-8,0000), and Maximum (15,0000).

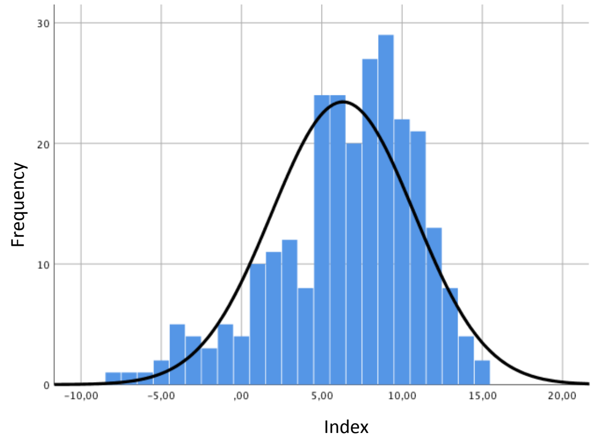

Figure 6: Samples' histogram distribution of the statistical analysis

With this, a level of 56% acceptance is determined for the electronic monitoring of the population under analysis. Within a 95% confidence level (P = 0.5), the accuracy of the responses reached an index of ± 6.3% (Dupont et al., 2017).

Accounting for the quartiles (Q0 - Q25 - Q50 - Q75) and the proportion of their population, Table 1, which indicates a higher or lower level of acceptance to EPM, it is possible to identify whether parameters for the sample characteristics (e.g., age, gender, etc.) can guide clusters of individuals. In this sense, multivariate statistical analysis was performed through SPSS-IBM to cluster the individuals. However, no characteristic of the sample was identified that was guiding the formation of groups of individuals, "more or less" favourable to the monitoring. The results and cross-analysis of sample characteristics and responses within the four quartiles (Q0 - Q25 - Q50 - Q75) are presented below. It should be noted that all values were determined to vary according to the statistical error of ± 6.3%; see exemplification in Table 1.

Table 1: Acceptance levels for electronic performance monitoring

Quartile	Total	%	Lower limit	Upper limit
Q0	20	8%	1%	14%
Q25	71	27%	21%	34%
Q50	156	60%	53%	66%
Q75	14	5%	-1%	12%
Total	261			

Conclusions

The applied survey allowed a very detailed view of a population predominantly of engineers (students and workers) regarding EPM at work. Surprisingly 69% of the respondents first knew about EPM through the survey. The population under analysis is more predisposed to accept monitoring to increase safety and evaluate health. Also, reward systems (financial, days off, and hierarchical advancement) are detected as factors that may facilitate acceptance of EPM. Raising people's awareness that monitoring makes it possible to improve performance can be a facilitating method for implementing EPM at work. However, the EPM projects' success needs to guarantee data sharing security and provide devices for the workers.

An expressive level of 56% EPM acceptance was determined. Within a 95% confidence level (P=0.5), the accuracy of the responses reached an index of ±6.3%, thus delimiting the determined level in the range of 49.7% to 62.3%. It is observed that 60% of the sample (156 respondents) is in Q50 (between 50% and 75%) from reception to monitoring. And that still is in the maximum quadrant, Q75, with an acceptance level greater than 75%, 14 respondents (5%). In this sense, there is a tendency (65%) in favour of electronic monitoring by the population under analysis. By how much, at lower levels, within Q25 (25% to 50%), there are 71 respondents (27%). And, with a completely opposite position (a level below 25%) to electronic monitoring, only 20 respondents (8%) were monitored.

Most respondents, 180 (69%), had, for the first time, knowledge about electronic monitoring at work through the survey in question. The population under analysis is more predisposed to accept monitoring when it aims to increase safety and assess health. Also, benefit systems (financial and days off) and opportunities for hierarchical advancement in companies are factors that facilitate the monitoring of electronic monitoring.

Raising people's awareness that monitoring enables performance improvement can be a facilitating method for including electronic monitoring at work. However, it is accompanied by the success of implementing transparent information monitoring and investment in processes that transmit security to workers regarding data sharing.

Abstract

This paper explores how the Trivarsity initiative addresses misalignment between AEC education and industry needs and its tangible results in showing the benefits and advantages for both staff and students of incorporating an interdisciplinary, multi-varsity curricular development into their European AEC programmes. Running annually since 2014, the collaborative BIM project has been an action research vehicle for an inter-varsity, interdisciplinary, collaborative design workshop, applying current and nascent digital tools and technologies. The constant re-alignment of AEC sector education to new, effective ways of working may ensure future proofing of educational provision.

Introduction

Background

This paper explores the benefits and advantages for both staff and students of incorporating an interdisciplinary multi-varsity curricular into their European AEC programmes. Effective and conclusive research generally provides evidence of what the curriculum in Higher Education Institutions (HEIs) should be (Emmitt, 2006). Through active participation in the research process, professional educators and students become clearer of the kinds of competence and attitudes which are critical for current and future effective professional performance (Schein, 1972). Businesses require graduates who not only have the skills to do the job, but who can aid the organisation to evolve in the face of continuous and rapid economic and technological change (CBI, 2012; Government of Ireland, 2019). Construction 2025 (Department for Innovation and Skills, 2013) reports on the future aspirations of the Architecture, Engineering, Construction and Owner/operations (AEC) sector, to include it being a world-leader in research and innovation which embraces Information Communication Technologies (ICTs) and smart construction. The NBS BIM report surveys the international adoption of digital tools and technologies (NBS, 2013; NBS, 2023), providing evidence of AEC sector practice now moving from the digital to the machine age. In digital construction, information is required at the level of data across the whole project eco-system. The radical change to the AEC sector disciplinary educational model, is in the application of the basal skills in practice of implementing digital tools, machine learning, and AI, necessitating the ability to design, manipulate and modify the (software) programming of architectural processes (Scheer, 2014, p.124): education needs to explore these innovative and disruptive developments in practice (nascent and emerging fields) to remain future-proof.

Methodological Approach

Research that aims to make projections about the future requires a *prospective* methodological approach (as per Ratcliffe, 2008). Through on-going, collaborative research between academia, industry and the professions, the future (r)evolutionary application of ICTs to professional practice across the disciplines in the AEC sector may be determined (as per *Industry 4.0* (Deloitte 2020)). Technical knowledge and skill are not enough in practice, the participants in a building project must have the necessary social skills to work together effectively and efficiently (Emmitt, 2010). The implementation of an emergent general plan for the integration of Building Information Modelling/Management (BIM/M) authoring tools and workflow methodologies, and soft skills into the curriculum of AEC sector education is challenging - it requires a methodological approach to systematically review forces for, and barriers to, effective change in terms of potential points of entry or intervention into the present educational system (Schein, 1972, p.90).

Action research: the active and interested participation by the researchers in the issue and processes being investigated so that they can identify, appraise and conjecture potential solutions is proposed. The intention of action research is to effect a change: knowledge gained through reflection on action is used to instigate ongoing evolutionary change, and to create knowledge about the process of change, the consequences of this change, and about the nature of the change itself (Fellows and Liu, 2008). Action research is complex and is appropriate for the study of future collaborative practice to inform education.

In the digital age, AEC sector educational evolution may mimic effective development in the I.T. industry, i.e., a *Dev Ops* cycle which is more like a figure of eight 'cycle', with continuous improvement of the product through feedback, reflection, adjustment, and concomitant improvement through the process itself (Kim et al, 2016; Kim, Behr and Spafford, 2018). At any point in time the product is deliverable but in a constant state of flux in terms of the understanding of its development. This is predicated on an approach to learning like 'transformative reflection' (Biggs and Tang, 2011 p.46) which is a multi-stage collaborative process of: reflect-plan-apply-evaluate which is then fed back into the iterative evolutionary development process. In vocational education, a renewed focus on the HEI developer ('Dev') co-creating course devisal/delivery and effective learning mechanisms collaboratively *with* industry operators ('Ops'), presents a symbiotic learning opportunity (see Figure 1 (Robertson, 2022)). All contributors, practitioners, educators, learners, and industry innovators may collectively test out the possible answers to the real world-relevant problems, and interdependently propose solutions, ensuring the alignment and interconnectedness of 'Dev' and 'Ops'. This adventurous type of learning better incubates and develops in students the skills they will need to apply professionally, involving activities with an element of professional, social, and emotional risk. Feedback from activities allow error to be used constructively (Biggs and Tang, 2011 p.65) following Emmitt and Ruikar's (2013) recommendation for through-project and post-project reflection and learning, thus, creating an academic community of reflective practitioners (Schön, 1983) and agile and socio-emotionally intelligent graduates.

HEI's current curricular development is often predicated on a protracted feedback loop. However, AEC sector in-house R&D is 'live' action research - an iterative feedback loop over a continuous two-yearly cycle but with opportunities for shorter term change implementation. Research-informed change in HEIs is challenged by bureaucratic structures and processes, and the reluctance to embrace change. A re-framing of change management in HEIs to the Dev Ops approach successfully adopted by innovatory practices, instigates a revolutionary change in professional education enabling it to remain relevant and travel in alignment with best practice.

The researchers demonstrate an analogous DevOps approach in the re-framing of the quality assurance (QA) mechanisms in their HEIs: the current emphasis on declarative (subject-specific) knowledge and threshold standards is shifted to include achieving 'threshold concepts', i.e., functioning (procedural) knowledge which informs appropriate action by the learner as 'performances of understanding' (Biggs and Tang, 2011, p.81), in order to propose 'satisficing' solutions (Simon, 1996) to industry-relevant problems. Practice problems often involve disciplinary professionals functioning in a 'silo' of specialisation, the research collective aim to bring conflicting 'silos' together to develop collaboratively a solution to the complex problems presented.

This DevOps approach is how that change may be most effectively accomplished in professional AEC sector education: as a partnership between active-research-informed practitioners and up skilled educators. To verify and validate HEI provision the learning mechanisms incorporate how people work, practice in action, patterns in practice, effective methods of action, interpersonal/ inter-professional relationships, and societal influences/events (like Covid-19) as per Seymour and Rooke (1995); Seymour et al (1997).

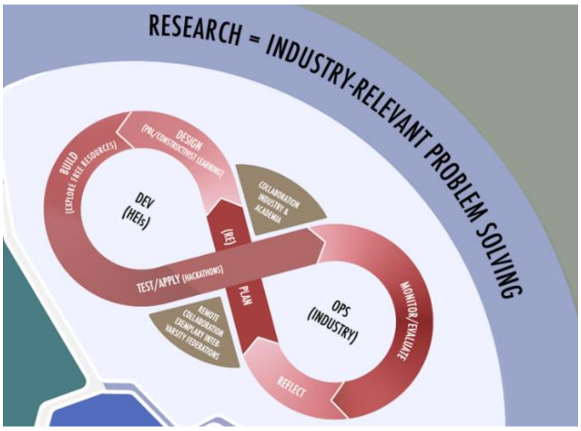

Figure 1: (Produced by Irina Vasiliu) DevOps Approach to Course Development: An on-going, cyclical process of collaborative research and development of the implementation of ICTs between HEIs and the industry (Robertson, 2022).

Reflection on the Cyclical Development of the Workshops (2014-2023)

The workshops started as a vehicle for staff and students to learn about building information modelling that was being mandated in UK, Ireland and Denmark. As educators in AEC, it needed to be addressed, because the curriculum was lagging and falling behind governmental policy. The collaboration outlined below started in 2014 with like-minded *'change agents'* (Schein, p.72, 1972) from academia identifying a *'specific change target'*; a collaborative BIM design project. They then instigated a change process to simulate 21st century, interdisciplinary, professional practice within academia. An inter-varsity, interdisciplinary, collaborative design exercise using industry-standard BIM/M software has evolved within a community of academic experts and practitioners in international HEIs.

In managing this evolutionary change process, the ultimate goals are continuously re-examined: it is a dynamic and cyclical process reinforced by the change agents finding a *'change role model'* (Schein, p.78, 1972). Autodesk, as thought leaders in the evolution of digital technologies in the AEC sector, are an apt change role model. This is a symbiotic relationship between academia and software developers involved in planned change, and the learners are a crucial group in the change-agent collective: their feedback is pivotal to the success of the cyclical development process.

The workshop collaborators from industry/practice (architectural, structural, environmental and MEP), professional education (multi-disciplinary academics and students) and software design and development (Autodesk) collectively review each workshop to identify driving and restraining forces and key barriers to its successful adoption into the existing educational system.

Trivarsity Workshop Development

The genesis for the workshop came through networking during the International Congress on Architectural Technology (ICAT) 2013, hosted at Sheffield Hallam University (SHU). Educators from SHU, England, VIA University, Denmark and Waterford Institute of Technology, Ireland (WIT now SETU Est. 2022). A common goal, with the onset of BIM mandates/legislation across the EU was to collaborate and mimic industry best practice utilising BIM methods and methodologies, upskilling staff and students in understanding and implementation of BIM tools across disciplines. Academia-Industry Partnerships (Thomas, 2013) have been fostered throughout each workshop with guidance, presentations and sponsorship. The first five workshops involved the original three institutes with a mixture of project types, selected to learn software and processes. As the workshop progressed student numbers grew as did the disciplines.

2015 SHU workshop explored authoring the 3D model to ease the downstream pricing/scheduling. The student groups involved Architectural Technology SHU, Derby and Huddersfield and Architectural & BIM Technology WIT.

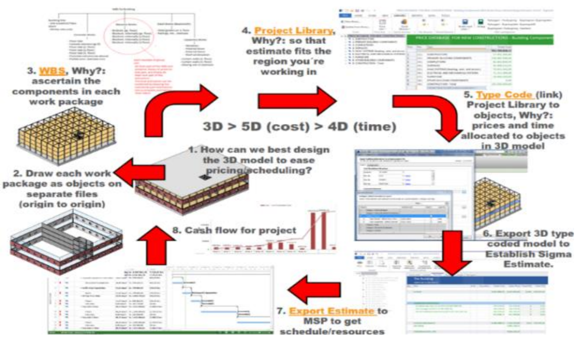

Figure 2: Infographic of Workshop workflow (Muller, 2014)

2015 VIA Horsens workshop introduced the discipline of "Architectural Technology and Construction Management" through the VIA students. This workshop used the same base models as the first workshop and introduced some remodelling aspects to optimise the daylight to the building. Students explored costing, external envelope design and daylight analysis.

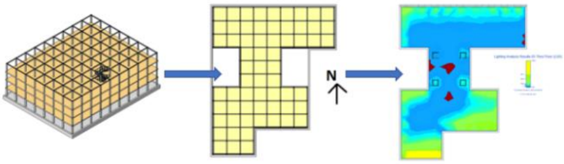

Figure 3: Group 6: Design Development and Analysis (Chisholm, 2024)

2016 WIT workshop introduced two new student disciplines from WIT; Sustainable Energy Engineering who return in 2023 and Quantity Surveying who rejoined in 2019 and have continued to be involved with Trivarsity. A key aspect of the workshops was introduced at this point. "The Prelude" is a period of 2-3 weeks prior to the physical workshop where the project and group members are introduced. The groups set up the CDE, BEP, MIDP, file naming conventions, project programming & roles; communicating through collaborative platforms; at this point it was BIM 360 and later workshops MS Teams. This has since developed to include shared online classes run simultaneously across all participating institutes. The workshop looked at the design of eight mixed use tall buildings to create a new district on Waterford Quay focusing on cost, programming, wind & daylight analysis, structure, architecture and MEP models. Each group had one representative who formed a master planning group to coordinate all groups. Figure 4 below shows them in discussion and the decisions made on the whiteboard.

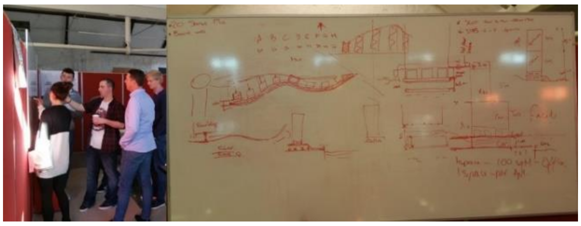

Figure 4: Master Planning Group (Chisholm, 2016)

2017 SHU workshop integrated industry practitioners as a group into the workshop. The principle objective was to explore, gain experience of and optimise the co-ordination of information between the disciplines on a simulated interdisciplinary refurbishment project utilising BIM360 and Autodesk Glue. Preparation work was undertaken during the Prelude. This workshop introduced clash detection and resolution to the students.

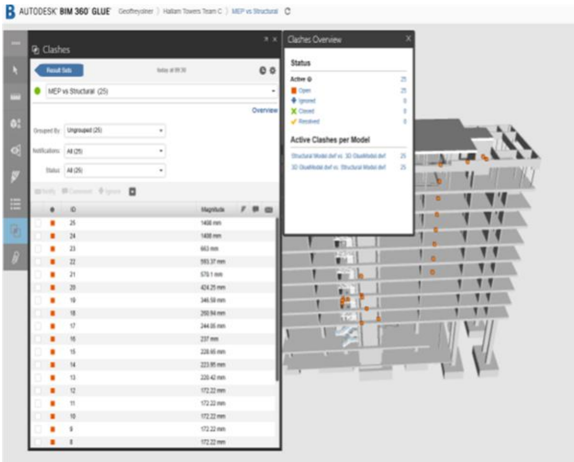

Figure 5: Team C: BIM360 clash analysis (Chisholm, 2024))

2018 VIA Aarhus workshop asked the groups to act as the design team associated with a design & build contractor in a bidding competition against the other teams for the design of a new student union building on the campus. A brief was set for the client requirements, a project programme was to be delivered along with costing packages and overall cost. The assessment of the workshop shifted from formal presentations to an exhibition style which saw each team produce an audio-visual presentation and two A1 posters, displayed in a common area. Refreshments were provided and each student and staff member then marked the projects based on the Most Economically Advantageous Tender criterion set out in the brief. This process has proven to be very successful and has carried on throughout all subsequent workshops. The benefits are seen in the students discussing and reviewing each others work within a social environment at the end of the workshop.

Figure 6: Exhibition & Marking, VIA Aarhus (Chisholm, 2017)

2019 WIT workshop saw VIA exit and Copenhagen School of Design and Technology (KEA) join Trivarsity with their Architectural Technology and Construction Management students. The WIT quantity surveying students took part again. The workshop built upon previous experiences with a design project based on the design and build tender for a tall gateway tower for Waterford Quay. Key aspects of the Trivarsity workshops were now in place: the prelude, multi-disciplinary (to a point) teams, working in the cloud to BIM standards, industry experts presenting, student social event with exhibition and marking to cap the workshop. The collaboration software had matured and the academic staff and students' knowledge had reached a point where the early day set up issues were eradicated.

Throughout all the workshops students could work remotely. This facilitated those who could not travel and added a vital aspect of the cloud collaboration experience.

Figure 7: Group Web call at WIT (Chisholm, 2019)

2020 SHU, the Covid workshop. With the collective experience gained through six Trivarsity workshops in cloud-based collaboration running a workshop during national lockdowns was not an issue. Tools such as Microsoft Teams and Autodesk BIM360 were now integrated into the workshops and our individual programme teaching. The entire genesis of Trivarsity workshops to work to industry best practice was tested with great success. The project dealt with a real SHU campus project, the proposed "Skills Factory". For the first time shared classes ran during the prelude and the workshop. New topics were MEP authoring and integrating Dynamo to size ducts. Both SHU & WIT were in lockdown, KEA were able to attend the classroom which resulted in some interesting dynamics with KEA students working in the one space and connected to the wider student/staff body via MS Teams.

Figure 8: KEA workshop and on the main screen Trivarsity Staff and group members reviewing project work (Sá, 2020)

2021 KEA. Structural engineering staff and students from Instituto Superior de Engenharia do Porto (ISEP) joined the workshop. This made a significant impact on the structural designs and the use of Autodesk Robot within collaboration process. The project was for the design of a new mixed-use district at Refshaleoen and to include building integrated renewables. SHU attended the workshop remotely due to travel restrictions. This was the largest Trivarsity to date with 16 No. groups comprising of 166 students taking part. This was the first Trivarsity workshop to be funded via the Erasmus+ Blended Intensive Programme (BIP). The BIP requirements matched the existing structure of the workshop with a mix of online classes and physical workshop. The length of the workshop increased from three to five days to include cultural aspects such as a river cruise and site visit.

Figure 9: Group 04, poster presentation (Chisholm, 2024)

2022 ISEP, BIP funded. Structural engineering staff and students joined Trivarsity from WUST, bringing more balance to the student disciplines. A comprehensive mix of cultural and workshop events were organised across the five days. The project was the development of a new urban area on the banks of the Douro River. Deliverables were consistent with recent workshops with highlights being the organised cultural events such as the river tour and bridge climb.

Figure 10: Arrábida Bridge arch climb (Chisholm, 2022)

2023 SETU, BIP funded. A return to Waterford and of SETU sustainable energy engineering staff & students, the introduction of Frederick University (FU) architecture & engineering students, and staff from ISCTE School of Technology and Architecture University Institute of Lisbon observing the workshop with a view to joining for the next iteration. The workshop consisted of seven institutes covering eight programmes/disciplines. The project was a revisit to the 2016 project with additional requirements to investigate cross laminated and glulam structure, environmental and embodied carbon analysis with Autodesk Forma and Insight tools. Again, a comprehensive mix of cultural and workshop events were organised.

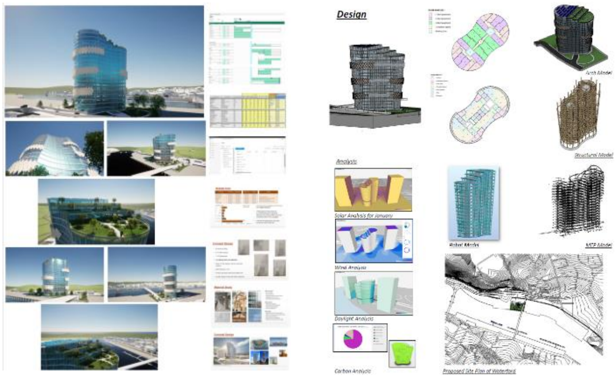

Figure 11: Group 03, poster presentation (Chisholm, 2024)

Trivarsity Impact on Programmes

Across all participating institutions the Trivarsity Workshops have had a positive effect on curriculum and teaching methods. Taking the three longest running members KEA, SHU & SETU, the impact can be seen in:

- the early adoption of BIM authoring tools, management and clash detection tools and the integration of these across years and programmes.
- support by software developers & vendors
- applied knowledge of international standards embedded into curriculum and programmes

- development of multi-disciplinary modules, workshops with their own institutes and locally.
- Senior years mentoring during workshops
- Development of BIM/Digital Construction focused modules building on the knowledge gained through Trivarsity

The impact of participation in Trivarsity for ISEP & WUST institutes who joined later, is similar but enhanced as they have benefitted from the preceding years development and body knowledge gained. Key effects are:

- Rapid amendments to curriculum across bachelor and master's programmes in areas such as, digital modelling & technologies, BIM fundamentals, management, standards & policies, digital surveying, AR/VR, digital twins
- Modifications to course delivery to include collaborative aspects improving teamwork and leadership skills and an uplift in the quality of student work.

Examples of didactical effects achieved in 2023 are presented in Figure 12 from WUST, utilising the software and methodologies from Trivarsity in their Bridge Engineering programme.

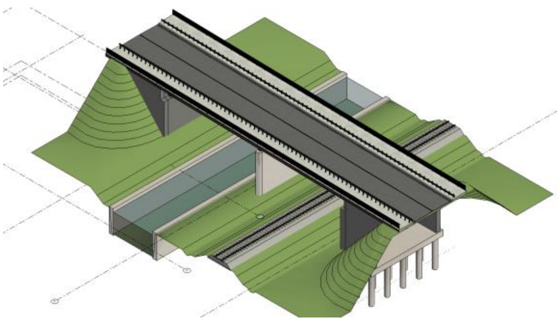

Figure 12: BIM model of a 2-span composite bridge (Hawryszków and Janicki, 2023)

Conclusions and Future Development

The ongoing success of the Trivarsity Workshops demonstrates the importance of interdisciplinary collaborative role-based teaching to allow students practice their discipline specific skillsets whilst gaining soft skills in teamwork and collaboration. Throughout the workshops skills are transferred between students across institutions and disciplines.

Trivarsity students are succeeding through engagement with WorldSkills International Digital Construction competitions, with SHU and SETU students winning medals at both national and international levels.

Staff are collaborating on research projects, studying PhDs at partner universities and the group have been asked to join the recently formed "I Build Sustainable and Smart" group. A European wide collective of educators with aims to broaden collaboration between institutes. One of the aims within the group is to disseminate the findings and knowledge gained through the Trivarsity Workshops to assist others to collaborate in a similar way.

Acknowledgments

The authors would like to Acknowledge the contribution of Academic staff involved with each Trivarsity Workshop.

DIGITAL PRODUCT PASSPORTS IN CONSTRUCTION – BARRIERS AND OPPORTUNITIES AT PEOPLE, PROCESS AND TECHNOLOGY DIMENSIONS

Pedro Mêda[1], Eilif Hjelseth[2], Diego Calvetti[1], Hipólito Sousa[1]
[1] CONSTRUCT – Gequaltec, Porto University Faculty of Engineering, Porto, Portugal
[2] Department of Civil and Environmental Engineering, NTNU - Norwegian University of Science and Technology Trondheim, Norway

Abstract

Digital Product Passports (DPP) will be inevitable as they pursue objectives aligned with the Sustainable Development Goals (SDGs). DPP is grounded in digital data, enabling integration and traceability throughout life cycles and value chains. DPP can play a central role in accomplishing twin transitions in construction. A People, Process and Technology (PPT) dimensions study aimed to fill the knowledge gap between strategies and sector visions—the mixed methods integrated approach collected data focusing on barriers and opportunities at each dimension. Focus groups analysed and clustered the results. Despite relevant barriers, construction stakeholders see opportunities and recognise the need, demonstrating eagerness towards adoption.

Introduction

Digital Product Passport (DPP) means a set of data specific to a product that includes, at minimum, relevant information for performance, environment and waste dimensions and is accessible via electronic means through a data carrier defined under the EU Ecodesign Regulation (European Parliament and European Union Council, 2022). EU legislation on the Green Deal and Data Act will make DPP a reality for different areas of activity in Europe and worldwide (Commission, 2022).

The construction sector is often labelled as highly resistant to change (Lines *et al.*, 2015). However, when awareness and a concerted change effort are made, the sector can behave and perform as one of the best. Stakeholders' realisation and perception of barriers and opportunities are crucial to anticipate implementation problems, better tune the support actions, and provide valuable and aligned contributions, fostering smooth transitions. This work stems from these assumptions, collecting impressions to forecast and support streamlined DPP implementation in the construction sector.

Despite some uncertainties on how the passports will be mandated, the objectives they aim to achieve are known, especially those concerning environmental targets and Sustainable Development Goals (SDGs) (United Nations, no date). According to (Munaro and Tavares, 2021), product passports are generally seen as a mechanism to influence consumer behaviour concerning sustainable purchasing and responsible product ownership. However, to accomplish this objective, many other aspects must be handled, enabling a broad range of services, businesses and possibilities and establishing a relevant ecosystem that should be anticipated (King, *et al.*, 2023).

Although recent, the DPP results from continuous work that has been ongoing for decades. The stakeholders' capacity for new requirements, more digital methods, and abilities related to products have been tested with EU-scale developments in areas such as energy efficiency and chemicals. However, there is the intuition that product passports might raise some fear across sectors due to the introduction of significant changes in how trade is processed and how product information is managed among all involved in the different value chains.

Several researchers have devoted their efforts to detailing and anticipating implementation challenges surrounding DPPs or associated concepts (Byers and De Wolf, 2023; Ducuing and Reich, 2023; King, *et al.*, 2023; van Capelleveen *et al.*, 2023). However, none have approached the topic from a People, Processes and Technology (PPT) dimension and grounded in visions from industry stakeholders. The motivation for this work is based on previous studies where the same research design was used to generate an improved understanding of the positioning of specific stakeholders regarding the use of construction technologies.

The research topic is the DPP for Construction Products. A survey is used as the ground for a mixed methods approach collecting quantitative and qualitative data from respondents in PPT dimensions. As part of the qualitative approach, specific questions for each dimension focus on identifying barriers and opportunities. A focus group involving the authors and experts analysed and clustered the answers and thoughts shared via open questions. The results aim to answer the following Research Questions:

- From the different PPT dimensions, how mature is the construction sector for DPPs?
- What ideas do stakeholders have regarding the opportunities and barriers raised by DPPs, considering the same dimensions?

This research comprises this Introduction followed by the research design and methods presentation. A brief overview is drawn on the origin and motivations for product passports, ranging from several sector perspectives to the specific features of the subject under investigation: Construction DPP. The survey structure and an overview of the quantitative data are presented. To end, the analysis of the qualitative results and overall discussion point to the conclusions section, where answers to the research questions are provided and summarised, endorsing the contributions, limitations, and paths for future works.

Research Design and Methods

The design for this research is inspired by previous studies (Mêda *et al.*, 2020). The reason for using PPT dimensions is associated with the imperatives for Integrated Design and Delivery Solutions (IDDS), where the use of collaborative work processes and enhanced skills, with integrated data, information, and knowledge management, aim to minimise structural and process inefficiencies and to enhance the value delivered during design, build, and operation, and across projects (Owen, 2013). As it will be detailed, this definition aligns with what Digital Product Passports aim to achieve. Complementary to this is the intuition that DPPs' accomplishment contributes to IDDS goals.

The integrated-use approach for mixed methods, according to (Cresswell and Poth, 2018), was chosen to perform simultaneously the qualitative and quantitative data collection using a survey.

After receiving the answers (the sample), the authors gathered a focus group formed by the authors and four experts to discuss the results, assess maturities, and analyse the most relevant barriers and opportunities identified from the PPT dimensions. Figure 1 illustrates the research design detailed above.

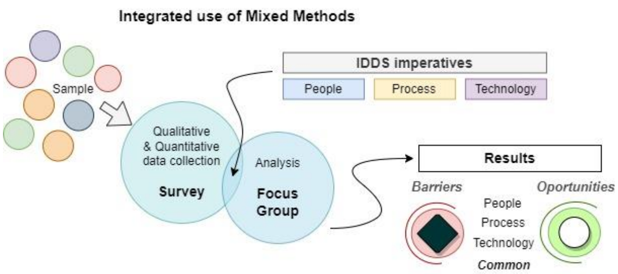

Figure 1: Research Design and method adopted in the study

Why Passport for Products?

When addressing a passport, most people understand it as a travel document issued by a determined country containing relevant information about the person who owns it. That information is secured and curated through time by authorities and individuals. This experience is based on a global standard that facilitates the understanding of passport information by all countries (Torpey, 2018).

Free trade and a single market of products and services constitute the EU's foundational principles. Over the last decades, rules and standards were developed to break down barriers to open trade across member states. Focusing on the free trade of goods, one of the key elements was the definition of a common framework of principles and procedures for marketing products (Official Journal of the European Communities, 2008). This set of rules was summarised on the CE conformity marking or "CE mark", indicating that a product meets the applicable requirements and has undergone the relevant conformity assessment procedures. This label has been working as a sort of passport "facilitating the understanding" between manufacturers, distributors, importers, and other relevant stakeholders across the EU and worldwide.

Performance characteristics were prioritised above all others. This was essential for confidence across markets and not to overcomplicate, ensuring feasibility and widespread implementation. Despite some shortcomings, in the construction sector, the process can be recognised as a successful (Ecorys, 2018), creating the needed background and opening paths to new interests and requirements.

Sustainability and environmental concerns command most 21st-century agendas (United Nations, no date). The product's characterisation imperatives regarding chemicals and energy consumption led the EU to increase the requirements and develop tools to disclose energy efficiency labels and track and disclose chemicals and substances of high concern (Agency, no date; Energy, no date). In this respect, and to improve the legal framework, the EU proposed a new Ecodesign regulation (European Parliament and European Union Council, 2022). The objective is to repeal rules currently in force, mainly concentrated on energy-related products, broadening the scope to a broader variety of products and making them more durable, reusable, reparable, upgradable, recyclable and less harmful to the environment (European Parliament and European Union Council, 2022). The proposal establishes performance and information requirements, supported by a digital instrument to streamline and facilitate data access, management, exchange, and traceability throughout the product lifecycle: the DPP. The proposal sets the link to specific product delegate acts to determine which information should be included and the accessibility rules to different stakeholders (European Parliament and European Union Council, 2022). For the case of most products used in construction, the Delegate Act will be the new version of the Construction Products Regulation (CPR) (Commission, 2022).

One of the most challenging aspects of this process is balancing the requirements with a successful and widespread implementation. In this respect and following the work developed by (King, *et al.*, 2023), it becomes clear for the European Commission that DPP objectives must be made more explicit, the administration costs for businesses must be anticipated, supported or limited, and requirements must be generated on a product-by-product basis, being determined in the construction products case, by harmonised standards.

DPPs must be perceived as an industry symbiosis enabler, given the amount of data that can be collected and managed and the viewpoints and stakeholders that can engage. (King, *et al.*, 2023) envisages an ecosystem for DPPs detailing the abovementioned aspects without focusing on a specific sector or delegated act. Among the many challenges identified is the awareness that such an ecosystem will operate within constraints (such as commercial interests, data quality and data ownership, a variety of sustainability metrics, privacy concerns, legacy systems, cost, skills, and current capacity) to achieve the sustainability values and goals of societal stakeholders (King, *et al.*, 2023).

In what respects the construction sector, DPPs should be additionally envisaged as Digital Twin (DTw) enablers at building scale (Mêda *et al.*, 2021), being a relevant part of the information structures being prepared to characterise built entities (Mêda *et al.*, 2022). Other initiatives originating from data-driven and waste perspectives, such as data templates, ISO standards, and material Passport initiatives, increase the complexity of this already delicate ecosystem (Honic, *et al.*, 2024). Formalising the discerning concept of passports is crucial, supporting decision makers' understanding and stakeholders' awareness of the full potential and realising the benefits together with the surrounding challenges (van Capelleveen *et al.*, 2023).

The first passport was designed to introduce changes in people's identification for the purpose of travelling across borders. By doing that, many services and business opportunities opened, most of which were not realised initially. DPPs are envisaged to pursue similar intentions and, most importantly, to enable a transformation in the product value chain supported by digital tools. The challenges for this endeavour in the construction industry are as broad as the opportunities, therefore justifying a multidimensional approach such as PPT (Derenzi *et al.*, 2009).

Development

Structuring the Survey

The survey was structured to suit a wide range of respondents. The initial objective was to share it via LinkedIn social media. Due to the number of lectures given to postgraduate students in different universities on DPPs' origin, main characteristics, and objectives according to the regulations, it was included as part of the teaching material. Google Forms was used as the support tool. An account subscribed to by the University of Porto was used to fulfil data protection requirements. Fifteen answers were obtained from the lectures that engaged a universe of sixty professionals. In this respect, respondents represent several areas of the construction value chain, from the primary sector (raw materials) to real estate and facility management, including architecture and engineering practice, manufacturing, wholesale, and owners. The answers range from six different European countries, and, in terms of professional practices, one-third has between 5 and 10 years, 26,7 and 20% has between 10 and 15, and 15 and 20 years, respectively. Lastly, 13,3% answered more than 20 years of practice. The survey is organised into five sections, promoting a brief explanation and capturing different types of respondents regarding DPP knowledge.

The Introduction and the Data management, positioned at the beginning and end, frame the study objectives, and collect relevant information regarding the respondents' professional experience, background, and geographic location. The three middle sections focus, as previously framed, on the PPT dimensions, setting a series of open questions with short answers and multiple-choice questions, where personal evaluations are to be provided considering four maturity levels, "Emerging", "Basic", "Advanced" and "Expert", with variations on the definitions depending on the dimension being questioned.

Table 1 presents the Process dimension questions as an example, as the changes are minor for the People and Technology dimensions.

Table 1: "Process" dimension questions used in the survey and presented as example

Question	Type of answer
How do you envisage the PROCESSES involving DPPs? (provide an answer based on a meaningful example from your perspective: awareness on how DPPs are to be structured and how they should be used as data providers for different outcomes throughout the construction life cycle; providing U-value of products for energy performance certificate issuance, among others)	open question with short answer
Can you provide an example of a process or outcome/deliverable that could benefit from the data set in a DPP?	open question with short answer
In your opinion, what might be the biggest CHALLENGES/BARRIERS at the PROCESS level regarding the implementation of DPPs?	open question with short answer
What might be, in your opinion, the biggest OPPORTUNITIES at the PROCESS level regarding the implementation of DPPs?	open question with short answer
How do you assess the existing PROCESSES for STRUCTURING and DELIVERING DATA for DPPs.	multiple-choice
How do you assess the routines' maturity for the DPPs to STREAMLINE PROCESSES during the Design, Construction and Use phases?	multiple-choice
How do you assess the routines' maturity for the DPPs to support PROCESSES contributing to the SUSTAINABLE GOALS (LCA, Level(s), others)?	multiple-choice

Quantitative Results

Different multiple-choice questions were prepared for each dimension to understand better and assess the respondents' maturity and their perceptions of daily practices.

Starting with the People dimension, when asked about their impressions of the level of knowledge regarding DPP, 42,9% pointed it as "Emerging", 50% as "Basic", and 7,1% as "Advanced". The same results were achieved for the questions focusing on awareness of the changes in EU Regulations that will make DPPs mandatory and how different stakeholders realise DPPs' benefits for the value chain.

A different landscape of answers was obtained for the Process dimension. When asked to provide a personal assessment of the existing processes for structuring and delivering data into DPPs, 42,9% classified them as "Emerging", 35,7% as "Basic", and 21,4% as "Advanced". Regarding the maturity of the routines to streamline DPP processes during the Design, Construction and Use phases, 50% considered these as "Emerging", 28,6% as "Basic", and 21,4% as "Advanced". When the question focused on the routines' maturity to support sustainability assessments and goals, 35,7% considered them "Emerging". The same result was obtained for "Basic", and 28,6% classified it as "Advanced". These results demonstrate higher maturity at the Process level if the scope is sustainability-related deliverables.

Concerning the Technology dimension, and when asked to provide a maturity assessment for existing tools to support and deploy DPPs, 21,4% considered these as "Emerging", 35,7% as "Basic", and 42,9% as "Advanced". Regarding the existing technology frameworks enabling information exchange for DPPs, 35,7% considered them as "Emerging", 35,7% as "Basic", and 28,6% as "Advanced". The last question impacted the data ownership and security topic, namely assessing the extent to which these concerns are being anticipated. 42,9% of the respondents considered them "Emerging" and the same percentage as "Basic". 14,3% considered them to be "Advanced".

From the overall view of the results for different dimensions, it is possible to state that higher maturity was achieved for the questions under the Technology dimension. This is not surprising compared to previous PPT studies (Mêda *et al.*, 2020). It is relevant to stress that interesting maturity levels are observed for some questions under the Process dimension.

Analysis and Discussion

Quantitative Analysis

Focus group participants were involved in previous PPT studies, meaning there is a knowledgeable but eventually biased view of the results. Given the topic's novelty and, more importantly, the absence of final decisions on its framework and contents, it was already expected to have low or 0% answers in all dimensions for the "Expert" maturity level.

It is worth noting that the lowest result obtained for "Advanced" in the Technology dimension is associated with data ownership and security, revealing stakeholders' concerns about how these issues are being safeguarded and explained. Still, in this dimension, it is interesting to observe the differences between the results of existing tools supporting and deploying DPPs and those enabling the exchange of DPP information. Respondents recognise that improvements must be made on the second.

From the dimension results, it is impossible to clearly state that Processes and People are falling far behind. When questioned on the routines' maturity to provide outcomes at the sustainability level, a relevant percentage of inputs was given for "Advanced". This situation may indicate that respondents recognise how the processes are aligned to provide these outcomes. In contrast, it might raise concerns about the inability to see how processes will handle others. Associated with these results might be the knowledge of systems and processes to deliver this type of outcome and how they need to be adjusted to accomplish the aimed integration. The people dimension lies behind all questions, namely if we look at the percentages obtained for the "Advanced" level. However, this confirms how awareness is needed. Complementing the legal picture of DPPs, such actions should focus on increasing the stakeholders' maturity where the lowest results were obtained.

Focus Group - Qualitative PPT Analysis

The first exercise consisted of grouping and clustering the answers for each dimension according to barriers and opportunities. At the Process and Technology levels, additional questions were made to improve how respondents see DPP implementation outcomes. These will be described as additional elements.

Starting with the People dimension, the lack of skills is identified as a constraint, confirming results from quantitative data collection. The absence of clear guidelines, reaction to change, the perception of the resources needed to systematise data, and concerns about data overflow can be highlighted as relevant bottlenecks. On the other hand, respondents clearly perceive how productivity can be raised with DPPs. As well as opportunities for business and innovation with a strong focus on sustainability. It is interesting to note that, from a professional perspective, DPP skills are envisaged as a relevant knowledge asset.

Looking at the Process dimension from the barrier's perspective, several concerns are raised regarding the cost of deploying and curating DPPs. Aside from the cost of technology (development/acquisition), respondents expressed concerns about the cost of changes at the process level and the human resources competencies needed. The requirements in terms of new processes, compliance with legacy systems and innovations and processes to ensure data quality and validity are also pointed out. On the opportunities side, the productivity gains, the timing for integrating processes, and the vision of how transactions and comparability can be streamlined are the topics respondents demonstrate higher confidence.

From the Technology dimension, the investment costs needed for new tools, the adaptation, when possible, of legacy systems and the management and update over time raise concerns. Interoperability, data security, and ownership are also aspects pinpointed as hurdles. From the opportunity's perspective, the data access, continuity, and the recognition of a data-driven approach as the background for digitalisation are the most recognised. Some respondents already forecast Artificial Intelligence (AI) developments to bring added value. In contrast, others strengthen how this can constitute an unparalleled opportunity to improve and widespread information management systems in construction.

These results prove that some barriers and opportunities range from more than one dimension; in some cases, they are common to the three. This vision steered the focus group discussions to produce the answers to the research questions.

Discussion on Barriers

Figure 2 clusters the main barriers framed within the dimensions and their overlap. From the core to the boundaries, the main concerns expressed by respondents, ranging from the PPT dimensions, are those associated with the costs, data collection and quality assurance. This aligns with some of the issues raised by EU entities regarding the final text for the regulations, where improvements are needed. However, their implementation should be feasible, scalable, and widespread at all levels. When looking at the overlap between People and Process, the perception of DPPs' value and the development of guidelines, standards, and supporting documentation are identified as the main barriers. In this respect, it is recognised that awareness actions and real use cases are needed as demonstrators and facilitators of the potential contributions of using DPPs. The idea is that these must, in the first moment, concentrate on the already identified goals, namely the ones associated with sustainability.

Notwithstanding, other topics should be presented, namely those that use the same data. This will provide an improved perception of the DPP value, not just for new requirements but also for the long existing ones, such as structural resistance or thermal behaviour. When looking at the identified potential constraints targeting the Process and Technology dimensions, the systems curation through time, hosting resources, update requirements, lifelong operation, and integration with legacy systems stand out. As all respondents have a professional practice, this result may derive from past experiences with systems replacement. This was pointed out in some answers. Establishing the framework and systems for DPPs must consider the objectives and all the relevant legacy tools and processes to accommodate the integration needs as best as possible. In addition, the framework should assume an incremental vision to accommodate more requirements and evolutions through time.

When looking at the aspects set in a single dimension and starting with Technology, interoperability, security, and ownership management constitute the main barriers. Respondents expressed the need to consider all the existing knowledge and systems architecture devoted to interoperability issues. When looking at DPPs from a multi-sector perspective, this aspect raises many concerns

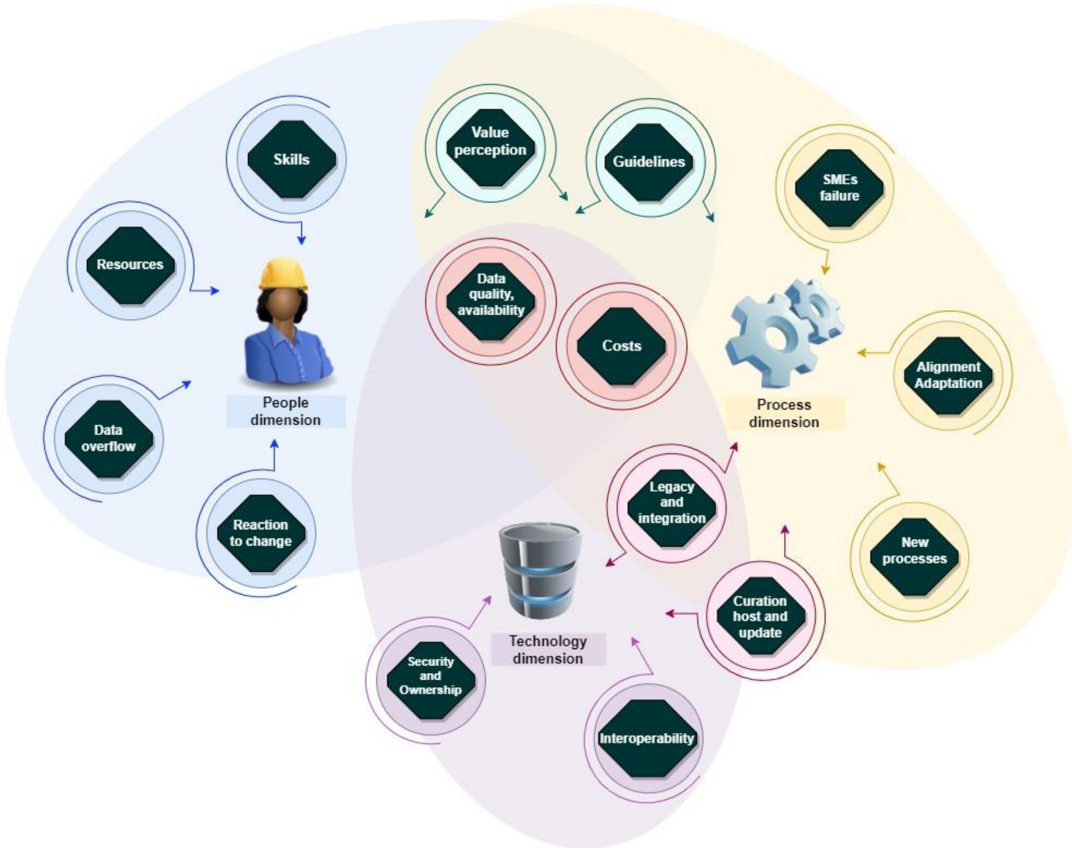

Figure 2: Main barriers clustered at People, Process and Technology dimensions

as several stakeholders are developing tools in silos. In construction, the topic is more safeguarded due to Building Information Modelling (BIM), meaning that developments can be built from the prescriptions set in BIM standards. This link and consensus favours overcoming the ownership and security of data issues. However, the DPP case will need new stakeholders, profiles, and restrictions. From a Process dimension, respondents pointed out three main barriers associated with the need to establish new processes or adapt existing ones, as well as the potential for failure from SMEs, given the dimension and demand underlying this transformation. The capacity to transform, keeping as much as possible or introducing effortless innovations, is a critical challenge common to most endeavours. In this case, and considering that most construction product manufacturers are SMEs, where some are very small, it is necessary to be aware of ways to support these structures to deliver successfully.

Finally, when looking at the People dimension, respondents identify some barriers when discussing innovation, namely reaction to change and lack of skills. The data overflow concern, the incapacity to collect and manage all properties for various products, is part of a data challenge that deserves in-depth research. This topic is associated with the lack of resources. In the present practice, many resources are wasted searching for data and keeping it in the head for some time to avoid getting lost during the processes. This somewhat "mental traceability" must be shifted by improving the ability to search faster and knowing where to access data or where it is stored in larger quantities. This is to say that, despite data overflow being a reality and an issue to prevent, misjudgements can, to some extent, blur this topic.

Discussion on Opportunities

Following the approach used for barriers, Figure 3 presents the landscape of DPP opportunities. Data integration, trust, and transparency stand out by ranging all dimensions under discussion. From the answers, it is observed that respondents understand relatively well the role of DPP and, more importantly, the transformations that it can bring to the construction sector if well implemented. Aligned with this are productivity gains and efficiency, also mentioned as joint opportunities. Only two aspects were identified as sharing two dimensions, one for People and Technology and the other for Technology and Process. Starting with the first case, an ample opportunity is imagined for the sector from data-driven developments, with many answers detailing the importance in having tools that manage and exchange data with a common understanding. Somewhat related is the

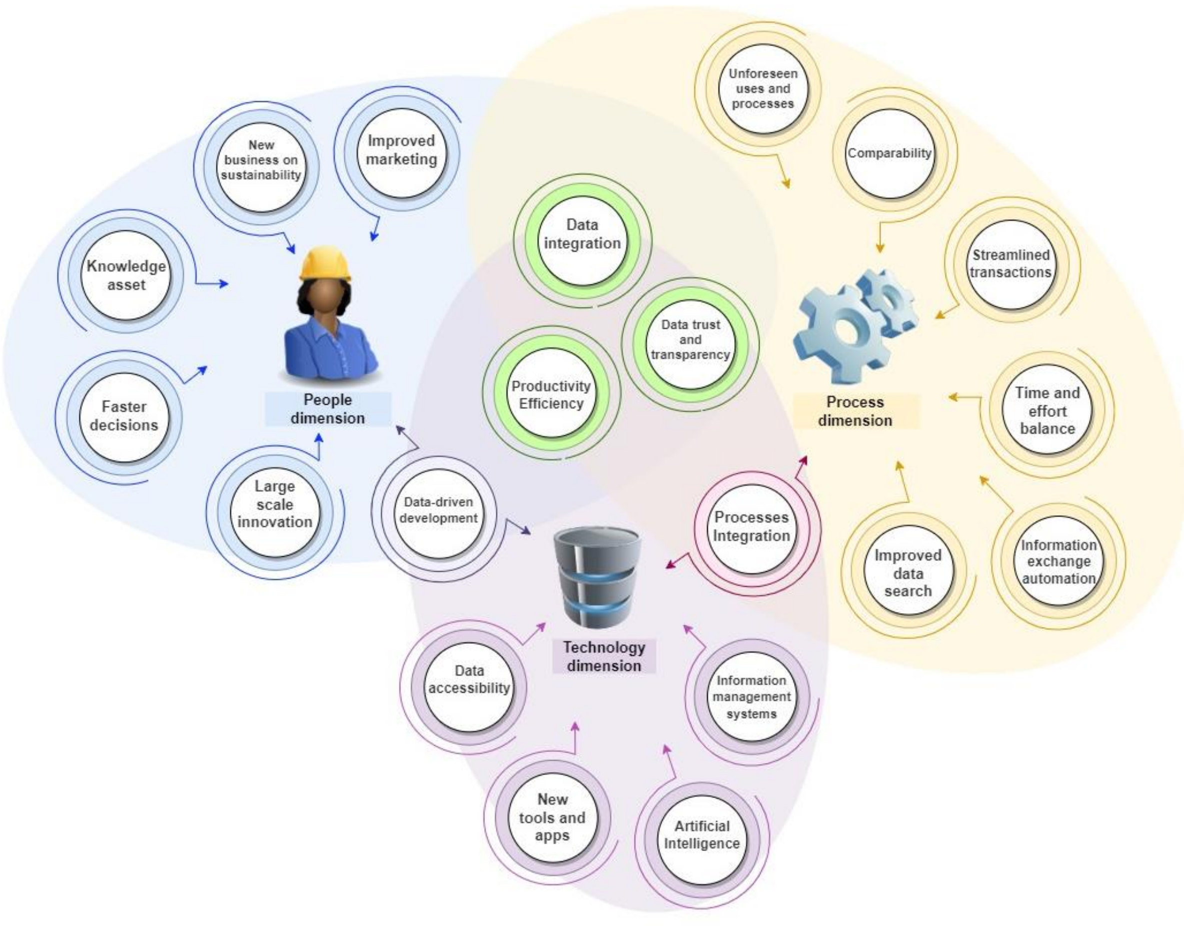

Figure 3: Main opportunities clustered at People, Process and Technology dimensions

other aspect, where respondents highlight the process integration as a game changer.

From a single-dimension vision, the identified opportunities are related to developing new tools and applications, namely information management systems that can support and efficiently administrate rich data environments. In this respect, many respondents pointed out the prospects in AI as essential to speed up and support data management. The last aspect mentioned by respondents reinforces the topic by highlighting the opportunities deriving from access to more organised and broader amounts of data. In the Process dimension, many answers focus on how the DPP-associated processes constitute an opportunity to find data better, increase comparability capacity, streamline transactions, and automate information exchanges. The results are very interesting because examples supporting these topics are provided, including all the construction process phases and the life cycle value chain. The expressed changes envisaged for the comparability opportunity from design to construction or during the bidding process were highlighted. The other topic mentioned is the unforeseen uses and processes. These answers reveal, to some extent, how the DPPs motivate and engage stakeholders. This enthusiasm must be used to tackle barriers previously addressed in the People dimension. Respondents state that improved marketing and faster decisions can occur in this respect. Some pointed out that new businesses can be built based on sustainability. Large-scale innovation is an opportunity deriving from the perception of how DPPs can work in terms of data integration. Finally, more than one respondent identified DPPs as a knowledge asset and an opportunity, supported by the idea that proficiency in this subject will become a competitive advantage in the short term, allowing more competitive professional possibilities.

Conclusions

From applying mixed methods and the People, Process, and Technology dimensions, it can be concluded that regarding Construction DPPs, the Technology dimension is more mature. It is also possible to note that a significant push should be made at the People dimension to provide awareness, guidelines, use cases and training to tackle erroneous value perceptions and reactions to change. DPPs are not a complete novelty. So, in the first moment, there should be a focus on what already exists and how DPPs can be built from it. Working on the outcomes deriving from the existing data is critical, making it part of DPP's information structure. The next step will be understanding the new requirements and the data needed for a comprehensive accomplishment. There are still unknown details on the passport framework and functionalities. The new regulations will bring about clarity. Despite the infancy of the concept and the absence of a full realisation, a solid background should be built using the known facts, fostering the conditions for a concerted change effort for the transformation to be consistent.

The research outcomes constitute relevant contributions, namely on how professionals engaged in the construction processes perceive DPPs and how their thoughts align with the strategies. When detailing the barriers, relevant bottlenecks were identified, targeting a single dimension from PPT, or ranging more than one, with cases comprising the three. The landscape of clustered barriers presents topics that are well-known and labelled as transversal to most innovation initiatives, whereas others can be recognised as specific from the DPP. As presented in Figure 2, the vision of the barriers can be paramount to tackle the main concerns in the short-medium time. Regarding the opportunities presented in Figure 3, it is relevant to stress that DPP seems to motivate stakeholders given the wide range of issues pinpointed and the associated comments. Relevant advantages can be taken from this enthusiasm, namely by establishing strategies to ensure a positive environment for the transition, engaging a high number of stakeholders and working on the most meaningful outcomes for each role. From this overview, it is relevant to highlight the similarity, in terms of pattern, achieved for the barriers and the opportunities.

The research is limited to the questions set in the survey and the sample, which can be classified as above average concerning DPP knowledge. The number of respondents could be more significant. However, it can be recognised that, due to the infancy of Construction DPP, few professionals can provide inputs such as the ones obtained. One of the objectives was to fill the gap in the existing studies by providing an overall perspective on the passport ecosystem for the construction sector when collecting insights from a multidimensional perspective. With the mentioned limitations, this was accomplished. Future research will focus on amplifying the sample and extending the number of questions and topics. A deep understanding of the motivations and reasons for the identified barriers and opportunities is also part of future actions. From the DPP perspective, future research will incorporate new elements as they become public, namely, the EU Regulations, when published, and discussions on the roles and implementation of Construction DPPs.

Digital Product Passports are inevitable in the EU as they are the cornerstone instrument of the digital and green transitions supporting industrial and carbon-neutral strategies. Despite the novelty, stakeholders identify the benefits and opportunities, expressing positive impressions towards a widespread implementation. Many answers state that what DPPs aim to accomplish was long expected, given the inefficiencies derived from manual work that is still mostly needed when using digital tools. This means the novelty is more on the concept than the features and enablers. However, given the push from the sustainability side, concerns are raised regarding the data overflow and the data priorities for the aimed goals. The situation is particularly relevant to SMEs as more support may be required to keep pace. To conclude, the impressions point to an easy understanding of the DPP and to a positive environment for its adoption in the construction industry.

The Construction DPP seems well-positioned to create a concerted change effort across the industry. Therefore, the capacity to set clear guidelines for this to occur is critical.

GAMIFICATION OF SAFETY TRAINING IN CONSTRUCTION: A UK PROFESSIONAL PERSPECTIVE

Charbel Ajaka[1], SeyedReza RazaviAlavi[1], Amit Kant Kaushik[1], Pablo Martinez[1]
[1]Northumbria University, Newcastle upon Tyne, United Kingdom

ABSTRACT

Most practitioners consider safety training in construction as a must-have but tedious and repetitive task. Novel technologies and learning approaches, such as gamification, have the potential to increase worker engagement and motivation towards safety training. This paper reports on the development of a game for safety training in construction and the game evaluation by a group of construction professionals. The study aims to evaluate the capacity of gamification to impact safety training. Based on the results, changing current practice to a more gamified approach to safety training and learning has a significant positive impact on safety awareness.

INTRODUCTION

The use of information and communication technologies (ICTs) have increased exponentially in the past decades, and educational institutions and their classrooms are no different. ICTs have been slowly but uninterruptedly introduced in the classroom to facilitate learning and acquiring knowledge, skills, and positive values. With the recent pandemic, it has become a fundamental pillar in improving students' attitudes towards learning (Lazar and Panisoara 2018; McGovern et al. 2020). Among ICTs, digital virtual platforms are revolutionizing educational experiences by providing simulated environments in which users can interact with the environment in an apparent real-time manner. These virtual environments can recreate classrooms, ensure safe experimentation of otherwise risky learning experiences, and often, a more viable and inclusive solution to overcome logistical and organizational challenges and expose learners to certain professional scenarios (Tzanavari and Tsapatsoulis 2010).

For construction education, for example, it facilitates bringing numerous students to a construction site at once, transforming the logistics and safety problems related to having students in a hazardous environment into a technological problem. From a technical aspect, virtual platforms are usually created to be accessed through various means. Hardware selection (e.g., flat screens vs. virtual reality) and the delivery method integrated into the software greatly impact the learning experience and outcomes. On that last part, an interesting approach that has been gaining popularity in the past years is serious gaming. This concept refers to a mix of gamification with an additional educational value that pushes the learner to use game mechanics in non-gaming contexts. It promotes learning, challenging performance, engagement, and personal initiative (Caponetto et al., 2014).

The rationale behind the gamification of training is, at its core, the need to change something within the learning process that is not working properly or adapt it to newer generation trainees. While health and safety in construction is a heavily regulated practice, with specific regulations at national and international levels, construction operations remain hazardous and high-risk workplaces. Gamification can be an approach to provide information at individualized levels (for operators, supervisors, technicians, etc.) an accurate and contextualized learning experiences (Benito Rodriguez et al., 2021). However, users' perspective on such games has not been recorded in literature, specifically from active professionals. This paper presents the evaluation of a safety training game by UK construction professionals, aiming to understand the benefits and drawbacks of gamified learning experiences.

LITERATURE REVIEW

Several studies have reported the success of gaming approaches for learning and skill development (Gee, 2006; Cavalcanti et al., 2021). A game environment presents an immersive environment full of stimuli that makes for an excellent sandbox to improve learning processes. Games are flexible in content and goals and can be used in a wide range of locations and engagement. This is especially important for flexible learning approaches in cases of worker availability disruptions, as occurred with the recent COVID-19 pandemic.

In a previous study, a framework for the development of games for construction activities was proposed (Le et al., 2015). Three modules are required for any game: a knowledge dissemination phase, a knowledge reflection phase, and a knowledge assessment phase. This approach has been used in the literature, and the results showed improvements in hazard identification (Bernardes et al., 2015). It also has proven applications in risk management to help learn activity interpretation and cause-consequence analysis through simulated scenarios (Barot et al., 2013).

Also, current literature highlights the dynamic presentation capabilities of gamified learning processes for safety training as a key element that supports higher immersion and learning outcomes. This is in line with learning theory regarding attention and visual cues. In fact, when delivered using virtual reality methods, games provide an additional level of dynamism and an improved learning experience (Harichandran et al., 2021). In this line, a large number of studies have been done over several learning training processes to address construction education. For instance, Kazar et al. (2021) developed a serious game for safety training and assessed its effectiveness with senior civil engineering students. Their results showed that the serious game is an effective training approach, and its effectiveness is not influenced by the game experience of the learners. In another study, Gallerati et al. (2017) assessed students' learning retention and the cost associated with training activities through serious gaming and VR. In their experiment, students used a simulated immersive VR that emulated a drilling land rig, the results showed improvement in learning retention and a reduction in safety risks and training costs. For flood safety training in the urban built environment, D'Amico et al. (2023) developed a non-immersive VR game, which could make a significant improvement in the self-efficacy and safety knowledge of the learners. The use of digital twin, which can dynamically update the digital models with real-time data, was studied by Harichandran et al. (2021) for developing dynamic VR games. They developed a framework for creating safety training scenarios from the project intent information, project status knowledge, safety regulations, and historical knowledge provided by the digital twin. Despite the novelty of the proposed approach, manual creation of the scenarios is reported as its drawback to be addressed in future.

This literature review has highlighted that the current implementation of serious gaming in AEC education has a lot of potential for education and training. Safety training has been identified as a key area for gamification. However, most of the existing studies focused on experiential learning for students, disregarding professionals who may have a more pragmatic approach to learning approaches (Abotaleb et al., 2023).

This paper explores how industry professionals perceive the introduction of serious gaming for safety training and how it compares to their current approaches. The population is a sample of AEC professionals who are actively involved in the construction industry, not necessarily around safety. Based on this, the following research questions are proposed:

1. What is the opinion of industry professionals regarding the gamification of safety training?
2. How does gamification compare to current approaches for safety training?

METHODOLOGY & GAME DESCRIPTION

The research is based on a quasi-experiment due to the lack of randomization in the testing group. The professionals involved in this experiment were selected based on experience and availability. A total of 28 professionals participated in the experiment in four different sessions due to space and availability constraints. However, a single group is created to check and evaluate the methods and learning outcomes presented through the experiment (see Figure 1). The learning activity is designed to introduce the population to two different concepts: site traffic safety from a trucker perspective, and crane safety from the crane operator and ground safety personnel. The first activity uses serious gaming to present different hazard profiles and safety procedures of driving across a congested and operational construction site while driving a loaded truck. Similarly, the second activity focuses on crane operations from two points of view, one while performing a module lifting operation from the cabin and the other one while doing a routine ground inspection around the crane lifting area. After the experiment, lasting around 40-45 minutes, a post-assessment point is given to allow the population to provide feedback and assess their learning experience.

Figure 1. Serious gaming for safety training activity.

To kickstart the learning activity, the participants are given a small tutorial prior to immersion in the game. The tutorial lasts about 20 minutes and covers the basics of the game experience regarding controls, main menu, and game structure and goals. This phase is meant to facilitate navigation within the game to all participants. Any participants who had difficulty with navigation or any game-related issue were provided with support and additional training.

After that, the participants start the game. They are thrown in first person on a construction site environment where they can interact with the main menu of the game (see Figure 2). This menu allows players to select the different levels available in the game. Each training topic/theme is structured as a set of levels, starting with a tutorial phase where participants are taught using visual cues and written statements regarding safety rules on specific scenarios that the participants walk into.

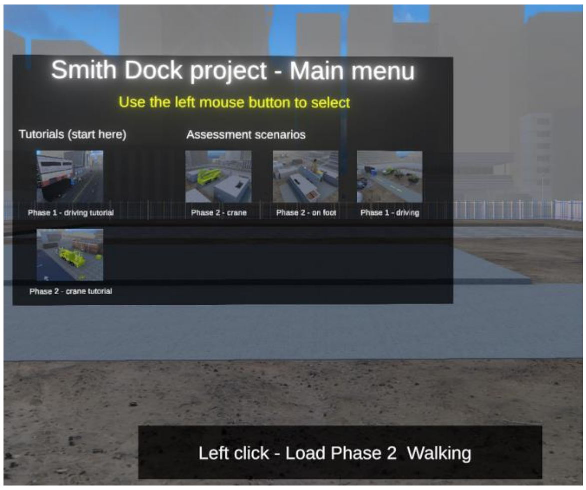

Figure 2. Screenshot of the main menu of the serious game.

Upon completion of the tutorial, an assessment level on the theme just covered is unlocked. This assessment level is similar to the tutorial level in terms of tasks and environment; however, no cues or support is given. A scoring system is introduced to automatically assess the results of the participant over their behavior and motion across the level. Participants receive their scores and feedback on how to improve the sections in which they lose points. The level structure is illustrated in Figure 3. Participants are free to navigate through the different tutorial levels at any given time, as there is no order to those levels.

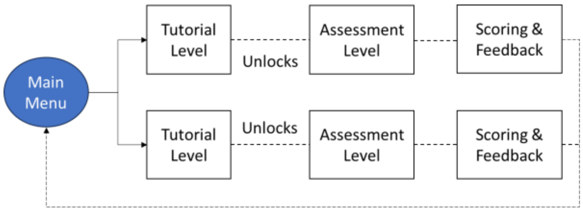

Figure 3. Game flow and level structure used.

The game brings the participants across different situations where safety training can be taught and tested. Within the same construction environment, that can be exported directly from BIM for additional user immersion, a large variety of scenarios can be proposed to imitate even the less plausible hazard profiles. While the safety training focused on traffic and crane operations, additional safety training elements of more generic nature can be added. For example, as shown in Figure 4, signage awareness or construction debris removal can be incorporated.

After the completion of an assessment phase, the participants are scored based on their performance, behavior, and interactions with the built environment. Performance is scored based on timing, behavior is scored around whether a set of safety tasks are done or not, and the interactions with the built environment are built as penalties (i.e., ignoring signage results in a loss of points). A final score is provided to the participant, with some feedback regarding potential improvement or where the participant was penalized. Then, the score is uploaded onto the leaderboard.

Once the participants are done playing with the game, about 40 to 45 minutes, a post-test questionnaire is given to each participant to fill. This questionnaire focuses not just on the learning experience, the game development, or the effectiveness and drawbacks of using serious gaming for safety training but also on prior engagement with safety training methods and current practice.

Figure 5. Signage included in the construction scenario for safety training.

RESULTS

This study and its protocol have received full ethical approval from the Northumbria University ethics online system (project ID: 5567). All participants gave permission to use the collected data. Initially, a personal assessment of the participants' professional experience and prior experience with safety training is provided. It allows us to showcase a better understanding of the participants and potential biases introduced by the population subconsciously. Figure 5 illustrates those results (left to right) for work experience, participant professional active field or background, and their prior experience with video games and safety training methods respectively. Note that the population is slightly biased towards early career professionals, with a current role in architecture or engineering. This will be addressed in

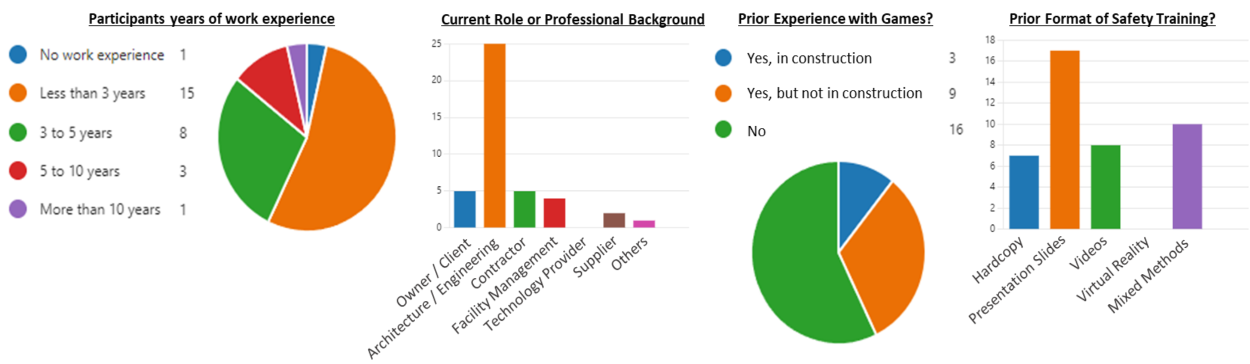

Figure 4. Experiment population data.

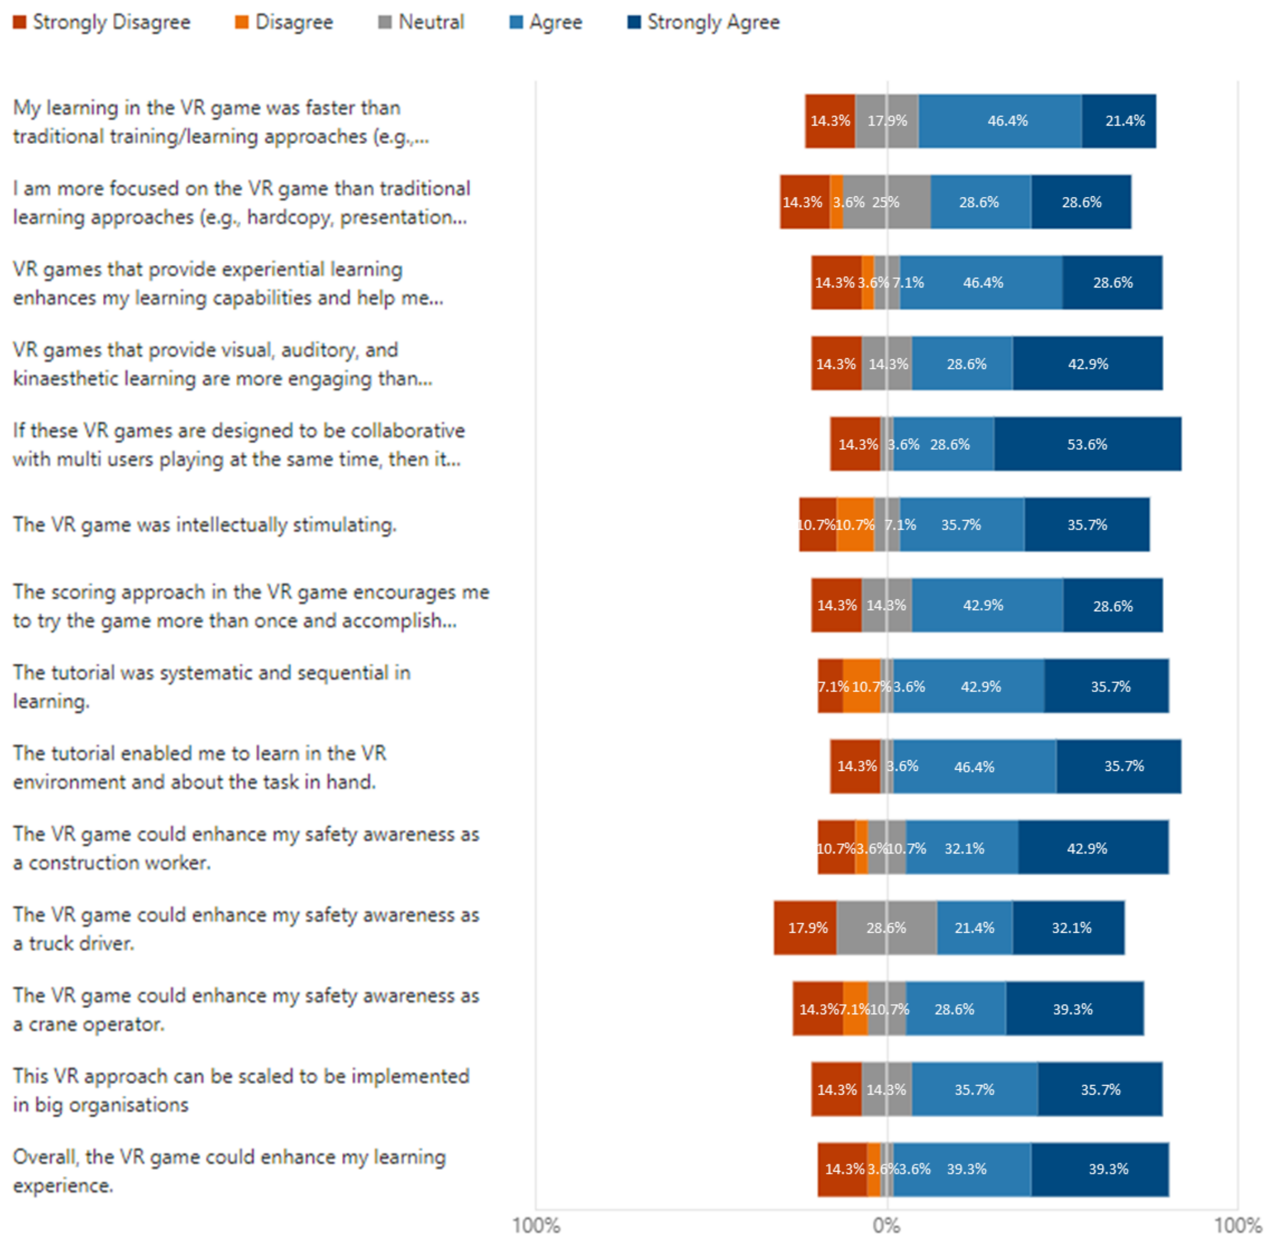

Figure 6. Participants' answers to the final questionnaire.

further experimental testing to provide a more homogenous population.

The results from the quasi-experiment can be found in Figure 6. Participants answered a series of questions using a 5-step Likert scale (1 – Strongly Disagree; 2 – Disagree; 3 – Neutral; 4 – Agree; 5 – Strongly Agree). Overall, the participants reacted positively to safety training through gaming instead of more traditional learning methods. Table 1 showcases the statistical analysis of the results obtained per question, in the order shown in Figure 6.

Table 1. Statistics of the questionnaire results.

	Questionnaire Results	
	Median	**Std. Deviation**
Question 1	4	1.235
Question 2	4	1.322
Question 3	4	1.305
Question 4	4	1.355
Question 5	5	1.361
Question 6	4	1.326
Question 7	4	1.278
Question 8	4	1.205
Question 9	4	1.291
Question 10	4	1.280
Question 11	4	1.402
Question 12	4	1.411
Question 13	4	1.319
Question 14	4	1.82

Based on the results obtained, on average, the learning experience of the professionals questioned is positive. The gamification approach is seen as an improvement of current approaches and can potentially increase safety awareness and training capabilities for operators/workers. The questionnaire results highlight the value given by the users of the collaborative aspect of the game (question 5), the immersion (question 4), and the increase in safety awareness when compared to traditional training delivery (question 10). Note that most professionals agree that the technology is scalable to an organization level.

However, more divisive results are obtained for certain questions: a more average neutral stance is given towards the efficacy of engagement and focus during the training of the game users compared to current approaches and the overall view of the game from a learning perspective is relatively neutral. Regarding those points, the participants could further elaborate on. Their feedback on possible improvements is listed below:

- Considering adding a story mode that simulates certification.
- Incorporating multiplayer.
- Improved tutorials for a broader range of users (especially non-gamers).
- Clearer instructions and transparency on the scoring system.
- Providing different camera angles instead of only first-person point of view.
- Better details and graphics for additional immersion, especially sound.

Separating the comments on improved technical performance, some of the desired improvements are of a complex nature. Developing certifications or learning assessments in a multiplayer environment would be an interesting challenge. While it challenges the idea of individual knowledge testing, it would probably be a more realistic representation of safety considerations and efforts on construction sites. As safety on sites is not an individual responsibility, could training be more effective in collaborative environments? Further research to explore feedback provided and perform more extensive evaluations on the potential of gamification will be pursued.

STUDY LIMITATIONS

The showcased study is a preliminary work to understand the impact of serious gaming on safety perceptions and training around hazards on construction sites, however the results obtained have to taken with the consideration of certain limitations in the scope and untested biases that can be accounted for.

For example, how the novelty of the serious gaming experience is affecting the perception of the usefulness of the approach by the users is uncertain. Or how the safety perception given by the gaming experience is translate onto the physical world. In the end, even the gaming optics of the criteria used to develop the training scenarios or even the scenarios themselves may had an impact on the experience outcomes that is uncertain.

Overall, multiple variables that would need to be accounted for are not considered in this study and should definitely be included in the experiment planning and posterior analysis to come up to more decisive conclusions.

CONCLUSIONS

The study's investigation into the use of serious gaming for construction safety training presents innovative findings. It demonstrates that gamification significantly enhances professionals' engagement, motivation, and safety awareness, offering a novel approach to addressing the complexities and hazards inherent in construction environments. The positive reception of the game's immersive and interactive features encourages a pivotal shift towards more dynamic training methodologies. This research enriches the academic discourse on educational technology by applying gamification within a novel context. It also provides evidence of its potential to revolutionize traditional safety training practices in construction. It underscores the efficacy of serious gaming in improving learning outcomes, thereby advocating for its integration into standard training protocols to better meet the evolving demands of the construction industry. The study outlines several pathways for future research, including enhancing game functionalities, exploring gamification's long-term impact on safety practices, and its scalability and cost-effectiveness. These potential avenues demonstrate further the role of serious gaming in professional education and its potential to transform safety training in construction and other sectors.

PRELIMINARY EXPERIMENTS WITH A HANDS-ON INTRODUCTION TO GENERATIVE DESIGN TECHNIQUES USING TANGIBLE OBJECTS

Divyanshu Bajpai[1], Vishal Singh[1], and Aradhya Singh[1]
[1]Department of Design and Manufacturing, Indian Institute of Science, Bengaluru, India.

Abstract

Generative Design (GD) is typically introduced to students through computer-aided design (CAD) courses. Diverging from this approach, this research uses hands-on experiments to introduce GD concepts to students. Shape Grammar (SG) and Cellular Automata (CA) techniques are explored using a tangible toolkit, distinct from CAD sessions. In an experimental setup, students use SG and CA techniques in separate sessions, following a think-aloud protocol. Data is captured using video recording. The study aims to uncover patterns in students' thought processes and assess if tangible exercises can instil confidence and interest in GD. The paper outlines the experimental setup, presents preliminary results, and discusses implications for teaching and GD tool development.

Introduction

Generative design (GD) is an iterative design process widely used in architecture to support human designers and help in design exploration. Various generative design techniques, including cellular automata (CA) (Herr & Ford, 2016; Von Neumann, J., 2017) shape grammar (SG) (Stiny, 1980), L-system (LS) (Lindenmayer, 1968), genetic algorithm (GA) (Jo & Gero, 1998) and swarm intelligence (SI) (Bonabeau et al., 1999) are reviewed based on preliminary literature review (Singh & Gu, 2012). In this paper, CA and SG have been introduced through tangible hands-on exercises.

Cellular automata (CA) is a collection of cells arranged in a grid of specified shape, and each cell changes state as a discrete time step, according to a set of rules depending on the state of neighbouring cells (Zaitsev, 2017). The essential components of CA are Cell, Cell States, and Neighborhood. Two kinds of cell neighbourhoods are usually considered in a 2D cellular automata theory. They are Von Neumann and Moore. Von Neumann's neighbourhood is considered in this work.

Fig. 1: Classical neighborhood in 2D CA a) von Neumann's neighborhood b) Moore's neighborhood (Zaitsev, 2017)

CA systems are widely considered in architectural design for their spatial abilities and form generation (Herr & Kvan, 2007; Krawczyk, 2002). CA produces unpredictable results after every iteration, which helps designers push their capabilities of creativity and imagination (Wolfram & Gad-el-Hak, 2003).

Shape grammar (SG) is a set of shape rules that can be applied to generate a set or language of design (Knight, 1999). According to Stiny (1980), the essential components of SG are a finite set of shapes, a finite set of rules, a finite set of symbols, and an initial shape. SGs are widely used to recreate architectural and design styles (Stiny & Mitchell, 1980; Poon & Maher, 1997; Stiny & Mitchell, 1998). The speciality of SG is to generate several design solutions using a finite number of shapes and rules. SG is widely used for design exploration and visual compositions (Tapia, 1999). The distinct feature of SGs is that they can be used as an analysis and synthesis tool to decompose complex shapes and generate complicated forms starting from a simple initial shape, respectively (Fasoulaki, 2008).

In this article, design experiments are performed with the help of a tangible kit relevant to solving the given problems using GD techniques. The design experiments assist in assessing and developing knowledge about the subjects' learning process and may provide a medium to support subjects' learning (Cobb et al., 2003).

Initially, the GD (CA & SG) technique is briefly discussed, followed by a background on related work. Then, the methodology is detailed, covering experiment design, subjects, data collection, and students' thought processes. Next, the experiment framework is outlined, including the problem description, constraints, rules, and setup details. Finally, results and discussions are presented, along with future work directions.

Related Work

Several studies have shown that incorporating GD techniques into design education can enhance the students' ability to explore design possibilities and improve their problem-solving skills (Fischer & Herr, 2001). These authors argue that design teaching should include more focus on techniques and skills in GD, especially in the initial stages of learning. Eris (2003) highlights the cognitive paradigm associated with the type of questions designers ask during the design process, which represents a convergent-thinking distinction. These studies also highlight the importance of hands-on experience in the learning process (Cassim, 2013). They present the findings from a case study of design students' reflections on their project experience. The reflections highlight the importance of hands-on experience with real-world problems in advancing a student's design knowledge and skills. Pusca et al. (2017) use case studies to show that hands-on activities can enhance students' knowledge and skills in design, creativity, communication, and modelling. They stress the importance of not only hands-on experiences but also minds-on to promote deeper thinking and understanding.

Junginger (2007) introduces the concept of "heart, hand and mind" as essential tools for design inquiry. However, most of these studies have focused on introducing GD through CAD systems (Krish, 2011 proposed a CAD-based design exploration method**;** Khan et al., 2019; Khan & Awan, 2018). CAD-based GD may not be accessible or appealing to all students initially because they need to learn to use the CAD tools and, perhaps, have adequate confidence in programming or coding scripts.

Hence, this research explores the effectiveness of incorporating hands-on exercises in teaching GD techniques, specifically using CA and SG. The goal is to determine if these tangible exercises can foster student interest and confidence in GD while improving their problem-solving and design exploration skills. The study also aims to analyse the students' thought processes during the exercises.

Numerous studies have explored the use of tangible tools for teaching computational and design thinking (Want et al., 2014; Lin et al., 2020; Matthee & Turpin, 2019). These studies highlight the benefits of using tangible tools in enhancing students' understanding of computational concepts and promoting hands-on learning. Soleimani et al. (2016) present a hands-on activity for the Computer Organization course in Computer Science using low-cost single-board computers. The results show that 90% of the students prefer hands-on activities to improve their learning and understanding of computational concepts. However, these studies have mostly focused on teaching programming concepts, not specifically GD. Marshall (2007) presents T-Maze, a tangible programming tool for children aged 5–9 to build computer programs in maze games by placing wooden blocks. Therefore, the current study aims to fill this gap by exploring the use of tangible exercises to teach GD techniques.

Research Methodology -

Experiment Design

The research on GD systems is often focused on reduced time and cost to achieve design alternatives, optimization, accuracy, consistency, and so on. Problem formulation and choice of the GD technique and representation play an equally important role, even if areas like optimisation steal the limelight. In this context, the experiment was designed to examine whether the tangible kit (discussed in a later section) can help students analyze the patterns in their thought processes while applying a GD technique to solve a given problem.

The experiments include three sub-experiments. Separate tangible kits are designed for each sub-experiment, as explained later in the framework section.

Subjects

The subjects for this experiment are postgraduate students in product design or undergraduates in architecture. Six subjects were selected, four from design and two from architecture. Although all the subjects have a background in design and architecture, they had yet to gain any knowledge of GD before this activity.

Experiment modules

The experiment sessions are divided into three modules. Each module has a demonstration video and reference manual explaining how to perform the activities. A moderator is still available during the experiment to clarify doubts (Toyong et al., 2020) and to ensure that the quality of recordings and data capture is acceptable. For reference, a demonstration video of rules and instructions is displayed on the screen throughout the activities.

Data Collection

Think-aloud protocol (Fonteyn et al., 1993) is used in the design sessions of approx. two hours, with approximately 10 minutes of break in between. The data is video recorded on tape, capturing both the verbal data and the evolution of the design through a camera directed towards the worktable with the tangible kit (Goldschmidt, 1994). A 10-minute post-session semi-structured interview was conducted with each subject, followed by open-ended feedback from the subjects about the whole experience. The interview (Patton, 1990) questions are outlined below -

Interview Questionnaire (Semi-Structured)

- *Which technique did you find easier to perform? Why?*
- *Any tangible thing or object you felt was missing from the experiment apparatus that'd have helped you during the experiment? Any suggestions?*
- *Which technique granted you more freedom while designing? Rank all three techniques.*
- *Did any part of the material or the experiment make you want to learn more about it?*
- *What part of the experiment did you find the easiest/clearest? What parts were unclear/more difficult?*

Feedback Questionnaire

- *What did you like about the experiment and its modules? What did you not like?*
- *How can we improve the delivery of content for better and easier understanding?*
- *Which content delivery method (manuals, videos, etc.) was most useful?*
- *Was there any ambiguity in any part of the experiment that halted your progress?*
- *Was the time allocated for reading manuals, watching videos and performing the experiment enough?*
- *Did you like the hands-on approach to learning Generative Design?*

A five-point Likert scale, a standard measurement method in educational research (Boone & Boone, 2012), is used. A specific questionnaire for each activity is developed. Data is collected from the subjects at the end of the activity. Each question has a declarative statement that measures one trait, such as measuring the challenges associated with a specific technique. Numerically, the scale is assumed to vary from -2 to 2.

- *The experiment has certainly helped me learn the Cellular Automata technique.* ***(SA | A | NAND | D | SD)***
- *The experiment has certainly helped me learn the Shape Grammar technique.* ***(SA | A | NAND | D | SD)***

- *The experiments conducted today:*
  Helped me learn more | Made no difference to how I learn | Were detrimental to my learning process
- *The Cellular Automata module of the experiment is challenging.* ***(SA | A | NAND | D | SD)***
- *I am comfortable with the activities performed in the Cellular Automata module.* ***(SA | A | NAND | D | SD)***
- *The Shape Grammar module of the experiment is challenging.* ***(SA | A | NAND | D | SD)***
- *I am comfortable with the activities performed in the Shape Grammar module.* ***(SA | A | NAND | D | SD)***
- *The Tangible Free Design module of the experiment is challenging.* ***(SA | A | NAND | D | SD)***
- *I am comfortable with the activities performed in the Tangible Free Design module.* ***(SA | A | NAND | D | SD)***
- *I'd like to have such interactive exercises in my courses.(* ***SA | A | NAND | D | SD)***

SA= *Strongly Agree |* **A**= *Agree |* **NAND**= *Neither Agree Nor Disagree |* **D**=*Disagree |* **SD**=*Strongly Disagree*

Data Analysis

The recorded data was transcribed (Tilley & Powick, 2002) and cleaned by an experienced transcriber. The transcribed data was subjected to thematic analysis (Maguire & Delahunt, 2017; Braun et al., 2016). Thematic analysis is an effective tool for identifying, analysing, and reporting patterns or themes within the data (Braun & Clarke, 2006). Two researchers independently conducted the thematic analysis for the whole transcript. The identified themes were reviewed again, and cross-checking against the transcription was done together. The questionnaire-survey results are analysed using descriptive statistics.

Experiment Framework

An exhibition layout problem was given for all three sub-experiments. The description of the problem is as follows.

"To design an exhibition space layout to display paintings such that there are four partitions/zones with similar spatial capacity. The paintings are displayed on stands such that there are an adequate number of surfaces to show the paintings. Adequate space must be provided inside the zones for visitors to walk and view the paintings. A 2D layout is expected (top view)".

Requirements and constraints on the display stand:

A display stand combines flat panels as surfaces for hanging the paintings. A panel is represented by a tangible object (matchstick), and a display stand is essentially a set of multiple connected matchsticks. The viewing angle should be between 90 and 180 degrees. These panels are to be placed so that the two sides of the panel – front and back – are easily visible to the viewers.

Experiment type and description

This work involves three sub-experiments with respective kits. The details of each experiment are as follows:

Sub-experiment A: Free tangible (FT) without rules

There are no predefined rules and constraints. A free, unconstrained space made of cardboard is provided. Tangible objects, including matchsticks, clay, thread, and clips, are provided. There is no explicit connection or reference to GD for this part of the experiment. The free-form thinking of the students is captured. Figure 2 shows an example of the layout created by one of the subjects. -

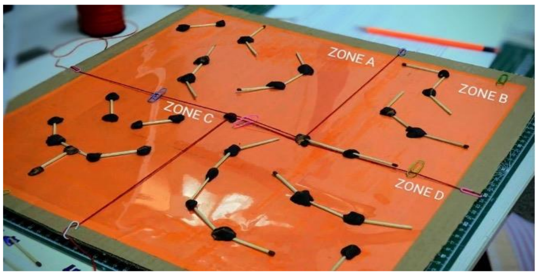

Fig. 2: Display structure layouts designed by a subject for an exhibition hall with four zones.

Sub-experiment B: Cellular automata tangible (CAT)

This activity addresses the challenge of designing the display structures using a cellular automaton (CA) kit while considering structural rigidity constraints. The subjects are constrained to use no more than five panels to ensure stability, and a closed-loop structure is excluded due to ensure dual-sided visibility. A grid outline serves as the canvas for CA operations. The tangible kit employs matchsticks for creating display stands distributed in a 2*2 grid. Subjects engage in two sub-activities, focusing on display structure and layout planning. The goal is to assess the tangible kit's effectiveness in instilling fundamental computational thinking for GD while fostering confidence and interest. Decision-making is pivotal as subjects adhere to predefined rules, with their choices and justifications contributing to the learning outcomes.

CA rule formation and application –

CA usually uses a grid, and state changes are made according to the neighbourhood conditions driven by rules. The rule formation is discussed below:

Two cell states are considered for this activity, named A and B (Fig. 3). The state of the cells in the next iteration is governed by the state of the neighbouring cells in the previous iteration. Von Neumann's neighbourhood is considered for this activity.

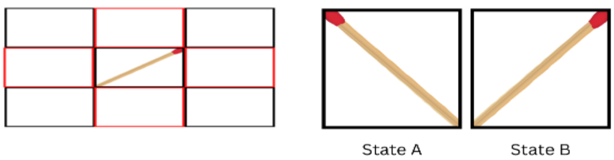

Fig. 3: Cell Von Neumann neighborhood

The following rules govern the cell state in the "New" iteration:

Rule #1: Assign cell state B if it has more neighbouring cells with state A; otherwise, assign cell state A if it has fewer neighbouring cells with state B.
Rule #2: If the number of neighbouring cells with state A is equal to the number of neighbouring cells with state B for some arbitrary cell position, then the cell state (in the "New" iteration) for that specific position is declared as:

Rule #2.1: State B (if the cell number of that arbitrary cell position is odd)

Rule #2.2: State A (if the cell number of that arbitrary cell position is even).

The three specified rules guide manual CA iterations. After three iterations, the subject evaluates the resulting display structures. Selection is based on logical assessment, requiring structures to maintain a continuous connection of panels (or matchsticks) without breaks for consideration. Figure 4 shows examples of some of the display structures generated by the subjects –

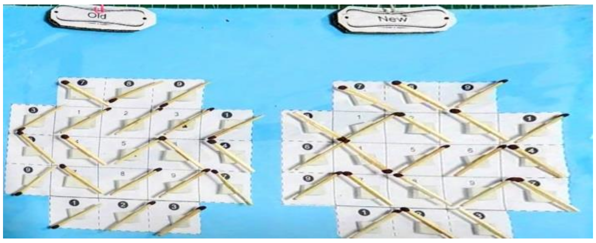

Fig. 4: Display structures obtained by a subject after performing an iteration of CA rules.

Once a display structure is selected, it is ready for arrangement in the four zones, marking the completion of the first part. Subsequently, three rules govern layout planning iterations, outlined below.

Arrangement of Tokens in the 4 Zones:

The chosen structures form four tokens through altered orientation and connection to a token's corner. Subjects can freely connect joints, ensuring the structure fits the grid. Design decisions and orientations must be explained, fostering robust decision-making. Figure 5 shows examples of tokens created by the subjects.

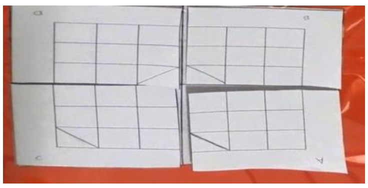

Fig. 5: Four tokens created by a subject.

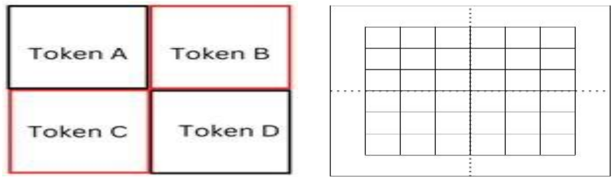
Following token creation, these states represent CA, contingent on the subjects' creativity. A 2x2 grid, forming four exhibition zones, is generated for placing tokens A, B, C, and D. The grid has a computationally generated initial configuration, and tokens follow a 3x3 structure with walking space around the periphery, exemplified for exhibition formation. Figure 6 shows an example of a token configuration to form an exhibition-



(a) **(b)**

*Fig. 6 (a) 2*2 grid for placing tokens (b) Tokens arranged to form an exhibition.*

The newly created 2x2 matrix is used as the basis for the next set of 3 iterations in adherence to the set of grid rules given below:
Rule A: If token D neighbours either token C or B (or both) in the "Old" iteration, the token in the "New" iteration at that position will be token A.
Rule B: If token B neighbours either token A or D (or both) in the "Old" iteration, the token in the "New" iteration at that position will be token C.
Rule C: If token A neighbours either token C or token D (or both) in the "Old" iteration, the token in the "New" iteration at that position will be token B.
Rule D: If token C, with an odd cell label number, neighbours either token A or token B (or both) in the "Old" iteration, the token in the "New" iteration at that position will be token D.
Rule E: If token C, with an even cell label number, neighbours either token A or token B (or both) in the "Old" iteration, the token in the "New" iteration at that position will remain token C.

Default Rule: If none of the above rules are applicable, copy the "Old" state into the "New" state without any changes.

After performing three iterations, subjects have three different layouts and can use their decision-making skills and the requirement to select or reject a layout. Figure 7 shows an example of one complete layout made by one of the subjects.

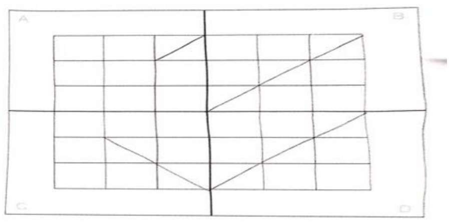


Fig. 7: A token layout obtained by a subject after performing the 3rd iteration on the 2x2 grid.

Sub-experiment C: Shape grammar tangible (SGT) –

SG has predefined shape rules, starting from the initial shape. This activity aims to analyze the subject's thinking pattern while applying this technique to solve a problem and whether the tangible SG kit can help subjects recognise the fundamental computational thinking approaches required in GD.

Two sets of rules are formed to perform this activity: the traditional SG rule to make geometric entities and the extension of SG called parametric SG (Angelo et al.,

2013) to make or play with the layout. Below are the rules for performing the SG activity –

Rule to Make Display Structure:

× - **Marker**

This rule is used to make display structures with the help of clay and matchsticks. There are two constraints that the designer should keep in mind when designing display structures:

- The angle between any two panels should be between 90 and 180 degrees.
- The number of panels should be less than or equal to five to handle structural rigidity.

Based on these constraints, a designer can make any number of display structures and name them entity 1, entity 2, entity 3 and so on. These entities will further help in parametric design rules. Figure 8 shows a few display structures made by subjects according to the above rule –

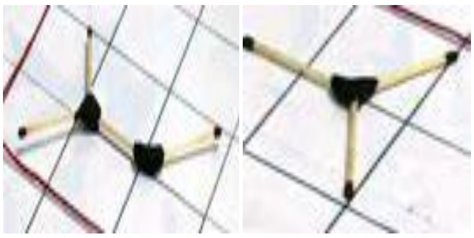

Fig 8. Display structures made by the subject

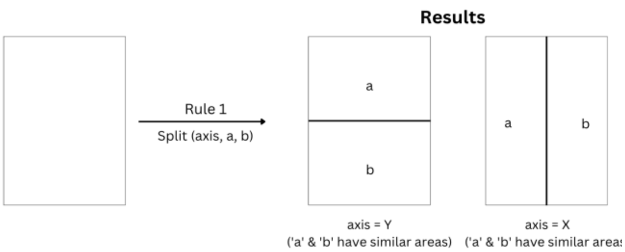
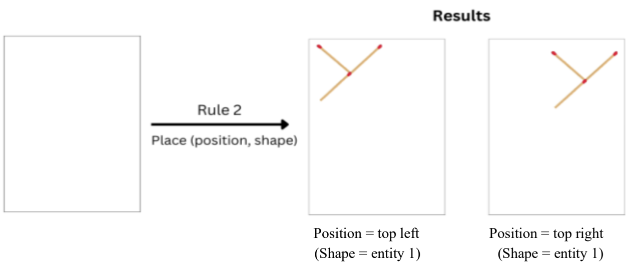
Rule to Design Exhibition Layout

A 10x10 grid with proper scaling and thread will be provided to the designer. The two parametric rules which will be used for the layout design are mentioned below-

Rule 1 –





- Entity1

Figure 9 shows an example of the layout created by the subjects with the help of the given rule and objects-

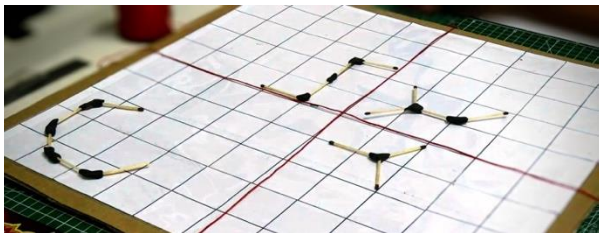


Fig. 9: Complete layout obtained using the SG rules

Table 1. summarizes the experimental setup.

S. No.	**Experiment (E) / Activities (A)**	**Timeline (minutes)**		
		Sub experiment A- FTD	**Sub experiment B – CAT**	**Sub experiment B – SGT**
A)	Exp Handout	COMMON (5 MIN)		
B)	Video Briefing	✓ 2MIN	✓ 15MIN	✓ 5 MIN
C)	Doubt Session	✓ 5 MIN	✓ 5 MIN	✓ 5 MIN
D)	Ref Manual	×	✓ 5 MIN	✓ 5 MIN
E)	Exp Activity	✓ 20 MIN	✓ 20 MIN	✓ 20 MIN
F)	Feedback	COMMON (10 MIN)		
G)	Questionnaires	COMMON (5 MIN)		

Result and Discussion

Four major themes emerged through thematic analysis of the transcribed data (Table 2). A detailed discussion of the themes is presented below –

User/Visitor Experience

This theme represents the importance of user flow in exhibition space layout. User flow is an essential aspect of spatial layout problems. Four out of six subjects spoke about the walking space arrangement of the panel, the field of view and the angle between panels (matchsticks), etc., to improve the visitor experience. For example, the experience of one subject is –

"*Even if it is rigid 90 degrees, the corner space will not be well utilized. Here it provides a larger space for the people to have a standard view, and even the angle of view will be better. So, this will be straightforward, and there will be the utilization of space. If it is rigid 90 degrees, the corner will not be very convenient for the flow.*"

– (Subject 4)

Here, the subject is describing the user flow along with the angle between panels when placing the display structure (entities in the case of SG) on free space.

Subjects' Perception of the Problems

Although each activity involved enough supporting media and small doubt clarification sessions, each subject perceived the situation differently. The response of one subject is –

“Just want to clarify? So we may have to make four zones, right? Similarly spatial capacity!. So what do you mean by similar like? Is it like the number of displays should be the same for this one?”

– (Subject 1)

Response to GD Techniques

This theme includes and represents the intuitiveness while performing the GD technique. Almost all subjects spoke about the ease of applying CA and SG, the ease/difficulty of following the rules, constraints, and the freedom while designing the layout. How the computational thinking approach is recognised while applying the GD technique is also a part of this theme. Below is an example of the interview session –

“Interviewer - which technique did you find easier to perform and why?

Subject 2 - If we talk in terms of performing, the last exercise was much easier because we have more options to do, I mean more things to do and with fewer complications, so we can just very freely work.”

This extract talked about intuitiveness in performing the GD technique. The subject found SG (the last exercise) easy to perform due to the freedom of design.

How the Kit Relates to Real-Life Problems

The tangible object and chosen problem statement make the whole experience like a real-life problem. Every subject visualized and tried to make the experience like designing an exhibition layout based on their understanding. Here is the experience of visualization of one subject while creating the layout plan –

“So this one is for having different and hear another theme. And similarly, this one like combines kind of these two, so one inclusive space kind and then have different themes on the outside”

– (Subject3)

Using codes for thematic analysis can help ensure consistency and rigour in the analysis process. By establishing a clear set of codes that define the themes of interest, the analysis can be more objective and less prone to bias. Combining codes to create broader themes can help synthesize the data and provide a more holistic understanding of the subject's thought processes.

A qualitative survey was collected from each subject based on the Likert scale to understand the subjects’ experience and whether such a simple tangible exercise can generate confidence and interest in subjects’ toward GD. The result of the study is presented in a graph (fig.10) below. The question is divided into three categories: FT design, CA, and SG. The responses of all six subjects based on the Likert scale (-2 to 2) are collected in three categories.

Table 2. Major Themes, along with a few associated Codes

Theme 1– User/Visitor Experience	**Theme 2–** Subjects Perception of the Problems.	**Theme 3-** Response to GD Techniques	**Theme 4-** How the Kit relates to Real Life Problem
Codes	**Codes**	**Codes**	**Codes**
Space for walking	Exploration of design space	Understanding of CA and SG rules	Geometry specific knowledge
Panel arrangement	Reinforcing problem objectives	Intuitiveness to perform	The relative size of the panel
Gallery theme experience	Doubt clarification	Design Freedom within and between techniques	Available zone space
Field of view	Constraint understanding	Computational thinking	Spatial Capacity
Angle arrangement between panels			

The incorporation of tangible kits into GD education has demonstrated positive outcomes in enhancing learning and comprehension. Subjects responded favourably to the tangible kit's effectiveness in teaching GD techniques, leading to improved understanding and comfort in applying each method. The kit facilitated the application of structured thinking, enabling subjects to explore a broader solution space—an essential aspect of GD. This hands-on approach allowed subjects to grasp computational thinking, offering insights not as apparent through traditional teaching methods.

However, challenges surfaced when subjects engaged in free-thinking activities, where the absence of constraints and ambiguity in design tasks led to negative responses. This suggests that open-ended design tasks requiring high levels of creativity and dealing with ambiguity can pose difficulties for some subjects. Despite these challenges, subjects did not express negativity regarding the comfort of performing each technique, highlighting the engaging and user-friendly nature of the designed experiment kit.

The study's findings emphasize subjects' positive responses to the tangible kit and its associated activities, particularly for understanding and comprehension. The contrast between activities with well-defined rules and constraints and the free-thinking task indicates subjects' potential struggles in open-ended design scenarios, suggesting the need for additional support to develop problem-solving skills in such contexts.

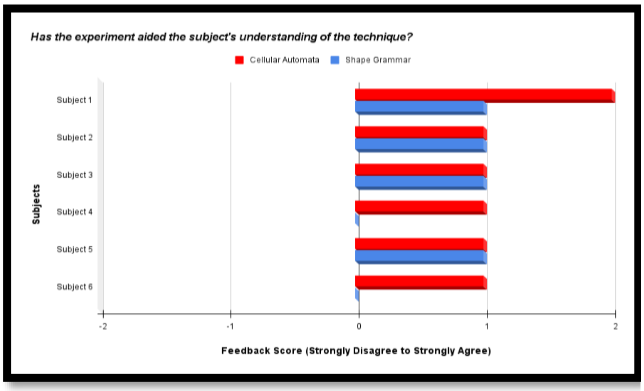
Subjects exhibited positive responses towards all the techniques in the kit, indicating their overall engagement and ease of use. This suggests that tangible exercises can be effective in teaching GD techniques and enhancing student engagement. Thematic analysis and code combinations were employed to delve deeper into subjects' thought processes, providing valuable insights for future design education practices.

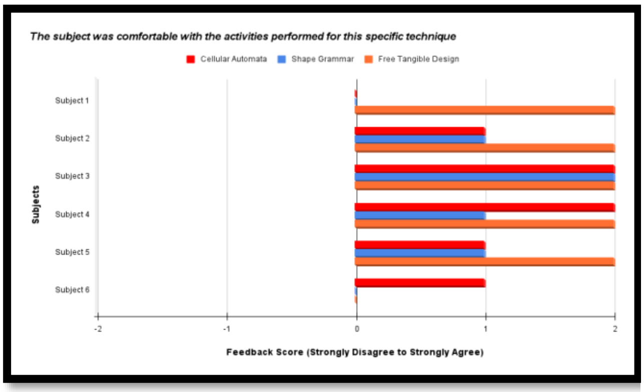
The study's methodology, including subject selection and activity time allocation, was carefully considered based on a pilot study. The pilot aimed to refine tangible exercises, ensuring feasibility and effectiveness, addressing potential issues, and guiding adjustments to the experiment procedures. While the sample size may be perceived as small, it aligns with the study's focus on exploring tangible exercise effectiveness. The comprehensive exploration offered valuable insights for educators and designers considering hands-on learning in generative design teaching.

The inclusion of diverse subjects with varying design education levels and backgrounds enriched the study's perspective. The multi-session approach contributed to an in-depth understanding of subjects' experiences, enhancing the study's qualitative analysis.

This research's significance lies in its potential to elevate GD education. The study offers insights into improved student engagement with complex design concepts by assessing the effectiveness of tangible exercises in teaching CA and SG. Addressing a literature gap, it specifically focuses on tangible exercises for teaching GD, potentially influencing GD education and tools development.

In conclusion, this research advances GD practices and underscores the transformative impact of hands-on learning in design education.





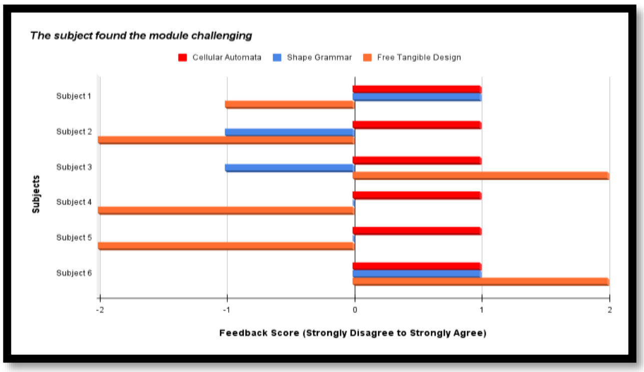


Fig.10 Results of subjects' responses based on the Likert data

Conclusion and future work –

Generative Design (GD) systems in architecture often employ various techniques, with two notable ones being Cellular Automata (CA) and Shape Grammar (SG). This study introduces tangible experiments using kits to enhance students' understanding of computational thinking in GD. The experiment aims to reveal cognitive processes and patterns in students' problem-solving approaches. Thematic analysis unveils insights into domain-specific knowledge and its role in design exploration. The findings underscore the importance of tangible exercises in fostering confidence and interest in GD, particularly in developing divergent thinking skills. The study acknowledges limitations, such as challenges in the free-thinking category, prompting the need for refined teaching methods balancing freedom and structure and the need for further experiments with more subjects having diverse backgrounds, which cover more diversity of student experiences and learning outcomes. Valuable insights into the effectiveness of tangible exercises using CA and SG emerge, suggesting potential extensions with additional GD techniques like L-system and Genetic Algorithm. Future work may include quantitative assessments of the experimental kit's efficacy and more detailed transcription analyses to identify computational thinking support. The future work could involve developing a taxonomy of knowledge based on the understanding of designers' and students' thought processes, identifying fundamental knowledge crucial in the generative design process. This research contributes significantly to design education, paving the way for future developments and exploration in the field.

AN APPROACH TO THE ESTIMATION OF DIGITAL TWINS TECHNOLOGICAL COMPONENTS

Giovanni Bortolin[1], Nicola Moretti[2], Karim Farghaly[2], and Weiwei Chen[2]
[1]Savile Brown Associates, London, United Kingdom
[2]Bartlett School of Sustainable Construction, University College London, London, UK

Abstract

The Digital Twin (DT) concept in the Architecture Engineering Construction and Operation (AECO) sector is gaining momentum. Various studies and case examples highlight its benefits. However, for broader implementation within the sector, there is a need for a standardised method for estimating the cost of DTs. This paper proposes an extension of the UK New Rules of Measurement 2 (NRM2) for estimating the technological components of DT systems based on the desired capabilities. The DT capabilities are identified through the analysis of the theoretical framework, which, combined with the analysis of current industry standards, enables the development of the NRM2 extension. The need for this extension has also been validated through a set of semi-structured interviews with industry experts in the UK. This research contributes to reducing ambiguity in the identification and estimation of technological components of DTs in buildings.

Introduction and background

The benefits of the digitalisation of the construction sector (still poorly digitised) are many and include addressing major challenges such as carbon reduction, resources and energy efficiency, labour shortage and competitiveness (European construction sector observatory, 2021). The digitalisation trend has been accelerated in recent years by the introduction of the DT concept, which can be broadly defined as "*A digital twin is a virtual model of an object, a system, or a process. It is connected to its real-world counterpart by a 2-way flow of right-time data, meaning it mimics it in all aspects. This helps us test decisions before we make them and understand how different actions might affect the real world.*" (UK Department for Business & Trade, n.d.). Though it is known that the DT concept has been investigated in several other sectors as aerospace and manufacturing (Grieves, 2016), there is no agreement on the components that should be included in a DT implementation (Shahzad *et al.*, 2022), thus it is hard to drive the digital transformation in the construction industry, with nothing more than a concept and a number of few custom applications.

In fact, the digital transformation in Architecture, Construction, Engineering and Operations (AECO) is not confined to the economic cost for the deployment of a new set of technologies. In the case of DTs, these costs can include for examples the change management activities required at the ecosystem level, training and workforce upskill, security, together with the hardware and software costs.

In the construction industry, innovation dynamics and therefore also the digital innovation, are often realised through projects (Xue *et al.*, 2014) and is well known that the success of a project is related to the careful estimation of the time, cost and quality of the desired outcomes (Association for Project Management, 2019). Within this context and with a focus on the economic dimension of projects, a careful cost estimation is key to understand in depth the required efforts to deliver the desired outputs and realise the client requirements and objectives. This is crucial, especially in the pre-construction phase in order to avoid cost overruns which could deviate completely the project scope.

The Bill of Quantities (BoQ) techniques are fundamental tools in the construction sector, used to control the project costs. To develop the BoQ it is essential to involve methods of estimations which respects standards in the way that different stakeholders will be able to understand it. One of the widely acknowledged standards is the NRM2 from the Royal Institution of Chartered Surveyors (RICS, 2021), which is used for detailed measurements of building works.

This paper proposes a method to estimate the technological components of DTs, required to deliver a finite set of general capabilities, identified from existing DT implementations. The method of estimation of DT in this paper is considered as a case of digital innovation in AECO which has not been completely explored and therefore requires further investigation. The paper also proposes a research roadmap on the study of the cost associated with the digital transformation in AECO.

The rest of this paper is organised as follows: the method section identifies the research methodology and tools used, the analysis of the theoretical framework analyse and identifies capabilities and technologies for DT systems, the NRM2 extension section showcases the developed standard for estimation and the preliminary validation through expert interviews, the discussion and conclusion refine what has been done against the identified research gap, and inform on the research limitations and gives direction on future steps.

Method and tools

The methodology used for the study is related to the design science research methodology (Peffers *et al.*, 2007), which is used for information systems as this allows the design of a method for the estimation for DT systems. The research methodology consists of six activities which are developed in sequence, the first activity, entails the identification of the problem statement, the second activity relates to the definition of the objective for a solution, the third consists in the design and development, the fourth is the demonstration, the fifth is for the evaluation, and the sixth consists in the communication.

Of the above-mentioned activities, the research focuses on the first three activities with the latter three and an outline of the next steps being discussed in the discussion and conclusion section.

The first activity is presented in the analysis of the theoretical framework, and results with the need for the development of a method of estimation for DT systems, which is needed for solving the identified research gap.

The second activity is identified through an understanding of existing standards of estimation and the relative implementation of estimation of DT systems, as currently, the research did not identify standards of estimation, this would accomplish a better identification of the DT systems in the phase of design and their related capabilities, and better define the DT requirements needed in the project.

The third activity includes the design and development stage, which is centred towards a developed method of estimation for DT systems for buildings, this is developed in the analysis chapter through the design of a method of estimation with the identified DT technologies capabilities.

Furthermore, a validation of the proposed method of estimation was undertaken through structured interviews in order to understand the experiences of the various construction experts involved in digital construction and in specific DTs.

NRM 2 to estimate DT systems

There are different guidance and standards used for estimation, and one of those standards, which is accepted internationally, is the New Rules of Measurement (NRM) collection, formed by NRM1, NRM2 and NRM3 and utilised as a guidance for estimating the building works throughout the lifecycle.

Furthermore, NRM can be taken into account in legal proceedings (RICS, 2021) and can be used to produce BoQs which follow the standard methods of estimation and can be attached as a contractual document in standard form of contracts.

The NRM1 is used for initial cost planning, the NRM3 is used for the estimation of building maintenance works, and the NRM2 is a standard for the estimation of building works during the pre-phase of construction and can also be used as a contract document which allows to obtain a total price for completing building works. This allows to evaluate the project variations and to support the management of the cash flow, implementing value engineering tasks. The NRM2 can be used as a tool to extend methods of estimation of DT, since it contains a method of measurement for quantifying the related systems and for the exclusion of the components already quantified using other parts of the standard (RICS 2021). Therefore, the proposed NRM2 extension aims at linking the DT capabilities with the technological implementation of both the hardware and software parts of DTs in buildings.

Analysis of the theoretical framework

To define the current costs associated with DT systems and their related technological components, in this section, we identify the current approaches that deliver the capabilities of systems, as described in the ISO 23247 series (ISO, 2021a). This standard provides a guidance for the development of a DT reference architecture and its correlation to the functional entities. Likewise, the DT application in building systems, assets and whole infrastructure involves the use of different capabilities that are summarised in Table 1. It has to be noted that the application level does not cover the use of DT systems for the benefit of the construction site.

The data acquisition capability (ISO, 2021b) is the functional entity for data acquisition and might also contain an Internet of Things (IoT) network, which links sensors, actuators and the collected data, supporting automation. Furthermore, data can be retrieved from historical building systems, as for example the Building Automation Systems (BAS) and Building Management Systems (BMS) (Lu et al., 2020).

The data modelling reflects the need to create a digital representation of the building and its features. It includes different data formats and their requirements (ISO, 2021c), which can enable data, process and system interoperability. For example, in Xu *et al.* (2023), the Industry Foundation Classes (IFC) standard and the semantic information in JSON file format are combined and converted into the 3D tiles standard for its interoperability.

The data analytics capability allows to gain insight or prediction from the data provided in the digital representation, as for example, in the case of Hosamo *et al.*, (2022), who describe the use of "the algorithms Artificial Neural Network (ANN), support vector machine (SVM), and decision trees to predict severe Air Handling Units (AHU) faults".

The actuation capability allows the use of the outcomes of the data analytics to automate processes and plan maintenance. This capability can be enabled through advanced functionalities of the IoT network which can enhance applications, as for instance the control of the Heating Ventilation and Air Conditioning (HVAC) system based on room occupancy as outlined in García-Monge *et al.* (2023). The curation of the DT system involves the maintenance of the whole system, this is done through the creation of appropriate data storage and its maintenance.

Table 1: Case studies and related capabilities

Application level	Purpose	Data Acquisition	Data modelling	Data Analytics	Actuation	Curation	Author
Asset	Human robot collaboration in Facility Management	Robot sensing data, asset data capture.	RDF and entity relationship diagram	Control flow for anomaly detection	Physical actuators and robot motion	Cloud based server, DB, web platform and BIM for visualisation	(Lu *et al.*, 2023)
Asset, system, building	Real-time monitoring of the hospital facility	Data on facility users, data on facility and processes	Web service, JSON Schema, Connection adapters, MOM	OLAP,HDFS, OLTP	Process control, defect detection, alarm rate of monitored points	BIM for visualisation, WebGL and JSON DB	(Han *et al.*, 2023)
System	Predictive Maintenance AHU	IoT sensor network, environmental sensing, and system monitoring	Brick ontology based on COBie data and IFC	ML, ANN, SVM and decision trees	Planning of maintenance	Sensor data DB and BIM for visualisation	(Hosamo *et al.*, 2022)
System	Anomaly detection of centrifugal pumps	Tags, environmental sensing, system monitoring, historic building data	Multi-source data through IFC and COBie	CUSUM and BOCPD	Anomaly detection and reduction of false alarms	BIM of the building and web based DT platform	(Lu *et al.*, 2020)
System	Fault detection and diagnosis of HVAC	Environmental sensing, and system monitoring	JSON file brick model with fault tags to form a hierarchical structure	Goodness-of-Fit test with Kullback–Leibler divergence	Unsupervised and supervised fault detection	Adaptive City Platform digital twin platform, which integrate brick schema	(Xie *et al.*, 2023)
System	Fan coils units fault detection for HVAC	Environmental sensing, system monitoring, IoT sensor network	Integrated data using BIM platform and NPM modules	Integrated anomaly detection flow chart	Fault detection	BIM and web based program	(Villa *et al.*, 2021)
Systems, spaces	Energy optimisation of HVAC	Environmental sensing, system monitoring, tags, data on facility users, IoT network	Integration of data through proprietary developed application	Quantitative data analysis	Decision through data analysis to improve efficiency	Web user interface	(García-Monge *et al.*, 2023)
Spaces	Monitoring of room occupancy	Image recognition and historical data	SQL database coupled with BIM model	Defined thresholds	Decision-making through a cost model	SQL Cloud server and BIM for visualisation	(Mannino *et al.*, 2019)
Building	Structural Health monitoring of building	Structural sensing, environmental sensing, computer vision	BIM with IFC and JSON for data exchange and 3D tile standard	Dynamic and static mechanical analysis	Building Structural health monitoring	SQL server to store data and 3D engine for visualisation	(Xu *et al.*, 2023)
Building, system, spaces	Indoor environmental quality, energy consumption, estimation of unobservable elements	Environmental sensing, systems monitoring, structural sensing	MATLAB backend software for data exchange between local software and the simulated building	CFD and ODEs for building zone dynamics	Detection of air contamination and test of fault diagnosis to improve protocols	Desktop application, cloud platform for remote access and as is BIM model	(Hadjidemetriou *et al.*, 2023)

This also involves the use of security systems for the collected and stored data, for example in a SQL database and a Building Information Modelling (BIM) model as showcased in Mannino *et al.* (2019).

Table 1 summarises not only the applications of the DT concept to several assets levels (i.e., assets, systems, spaces, and buildings), but also allows to identify the technologies implemented for each individual capability in the analysed DT case studies. This forms the knowledge basis used for the development of the NRM2 extension. The identified technologies are in fact generalised and indicated as possible cost which must be considered in the design phase, for the estimation of built asset DTs.

The NRM2 extension

The developed method of estimation is outlined in Figure 1 which showcases the different types of components needed for estimation and avails of the current format of the NRM2 estimation standard which also includes a section including items already incorporated in the NRM2. The estimation method designed includes sections for components which are identified through Table 1. The multiple technologies needed for each capability are differentiated between hardware components and software components. The costs related to the hardware technological components is estimated as their prime costs as the supply rate for goods (RICS, 2021). On the other hand, for software technological components, the cost is related to time-related variables.

Data acquisition

The data acquisition includes within sub-component 1.1 the cost of installation of the data acquisition source and its associated prime costs, these data acquisition sources can be and are not limited to sensors of different kinds and QR Codes tags. These sensing technologies should be considered in addition to the BMS/BAS parts and are typical of DT implementations (e.g., occupancy monitoring sensors, air quality, indoor comfort etc.)

As this requires the installation of a physical element the quantities will be enumerated (nr) and for systems which could include multiple data acquisition sources, the quantities might be itemised (item). These data acquisition technologies have all different costs associated with their installation and require separate analysis.

A time related charge is allowed for the process related to its installation and the duration that the data acquisition source will have to stay in position during the construction phase which could include the protection to other type of works undertaken on site.

Furthermore, by following the process of installation of the data acquisition technologies, there is the need for installation and temporary maintenance of communication technologies. Thus, the sub-component 1.2 in the data acquisition section could require batteries or cabling - such as an ethernet cable as seen in the ISO 23247-:2021(ISO, 2021c) - directly to the data acquisition source, hence quantities might be itemised for systems or numbered for single priced components with a fixed charge or time-related charge. Furthermore, the NRM2 extension allows the possibility of integration of historical building data (sub-component 1.3), as outlined previously. For example, through BMS/BAS data, quantification can be itemised and have a fixed charge which would describe the type of data and the related cost for provision.

Data engineering

The data engineering includes the capabilities identified in the data modelling and the curation detected in the analysis of theoretical framework. The sub-component 2.1 includes the preparation of a digital model for the target assets processes and their interrelations. For this purpose, the BIM approaches can be used as well as other Modelling and Simulation (M&S) methods which should be identified and quantified as items. BIM, in fact, is an information management technique that follows the project life cycle. For this reason, a complete data management platform needs to be developed and costed, in support of the DT functionalities which need to be curated along the DT lifecycle. The included sub-component 2.2 includes the data storage and its related maintenance. Sub-component 2.3 regards the implementation of security systems and their quantification is itemised. Sub-component 2.4 regards the data access and interoperability which reflects the need for producing and using structured information in DTs. This allows systems, processes, and data interoperability. Since multiple methods could be used, quantities need to be itemised with each system separately, to identify the associated costs and pricing method (e.g., fixed charge or a time-related charge).

Data analytics

As there are multiple approaches for data analytics which could be developed, with different systems and which needs distinct correlated works, each individual data analytics techniques might identified (as outlined in Table 1). The data analytics method should be stated, and the quantities separately itemised and quantified to identify the associated costs and pricing method (e.g., fixed charge or a time-related charge).

Actuation

The actuation includes the sub-component 4.1: the installation of actuators of the building systems which facilitate the building control and automation of the spaces and equipment. These components should be considered in addition to the BMS/BAS. Furthermore, the included sub-component 4.2 will have to include the installation and temporary maintenance of communication technologies, which could require installations with batteries or cabling such as ethernet cables as in examples outlined in the ISO23247:2021(ISO, 2021c).

Digital Twin System

Component	Included (Sub-Component)	Unit	Pricing method	Excluded
1 Data acquisition.	The type of data collection source to be provided should be stated, with each type separately quantified: **1.1** Installation charge of data collection source.	item/nr	**1** Fixed charge **2** Time-related charge	**1** Operation and maintenance manuals (included in B.12 Contractor's cost items: completion and post-completion requirements). **2** Preparation of handover plans (included in B.13 Contractor's cost items: completion and post-completion requirements). **3** Inspection (included in B.13 Contractor's cost items: completion and post-completion requirements). **4** Training of building user's staff in the operation and maintenance of the building engineering services systems (included in B.13 Contractor's cost items: completion and post-completion requirements). **5** Information model and information management for BIM (included in A.9 Employer's requirements: building information modelling (BIM)). **6** Mechanical services system (included in Work section 38: Mechanical services). **7** Electrical services system (included in Work section 39: Electrical services).
	1.2 Installation and temporary maintenance of communication technologies.			
	1.3 Provision of historical building data.			
2 Data engineering.	The type of digital representation should be stated and if the representation avails of a BIM model: **2.1** Preparation of digital asset/process representation.	item	**1** Fixed charge **2** Time-related charge	
	2.2 Data storage and maintenance.			
	2.3 Implementation of data security system.			
	The method used should be stated with each method separately quantified: **2.4** Data access and interoperability.			
3 Data analytics.	The method used should be stated with each method separately quantified: **3.1** Work related to data analytics with supplied data and prediction algorithms.		**1** Fixed charge **2** Time-related charge	
4 Actuation.	The type of actuator to be provided should be stated, with each type separately quantified: **4.1** Installation charge of actuators.	item/nr	**1** Fixed charge **2** Time-related charge	
	4.2 Installation and temporary maintenance of communication technologies.			

Figure 1: Proposed method of estimation for DT systems based on the NRM2 structure.

Excluded components

Other tables and existing components already included in the NRM2, which may overlap, are excluded for clarity purposes. These are the operation and maintenance manuals (included in B.12 contractor's cost items: completion and post-completion requirements), the preparation of handover plans (included in B.13 contractor's cost items: completion and post-completion requirements), the inspection (included in B.13 contractor's cost items: completion and post-completion requirements) and the training of building user's staff in the operation and maintenance of the building engineering services systems (included in B.13 contractor's cost items: completion and post-completion requirements), the information model and information management for BIM (included in A.9 employer's requirements: building information modelling - BIM), the mechanical services system (included in Work section 38: Mechanical services), the electrical services system (included in Work section 39: Electrical services).

Validation of DT Systems designed method of estimation

The next stage of the research concerns the validation of the proposed NRM2 extension. For achieving this, a series of interviews with four experts was carried out. The participants were high-profile professionals in the fields of digital construction and have been selected based on their standing in the UK industry.

A total of eight open questions were asked in semi-structured interviews and are summarised in Table 2.

Table 2: Interview questions.

Question	
1	What is your current profession and your expertise in the AEC industry?
2	How would you define your experience in DTs generally? Also, do you have any experience in estimation for building works?
3	Do you think that DTs are beneficial?
4	What is your current opinion about DTs system for operation and maintenance?
5	Do you think the current proposed section can be used in your profession and why?
6	Can you suggest any improvements to the proposed new section of the NRM2?
7	Would you adopt this section for future implementations of DTs?
8	Do you think the current section could help other professionals in future implementation of the DT systems in the built environment?

The experts' profiles are summarised in Table 3.

Table 3: Summary of interviewed experts

Expert	Profession and expertise
P1	Planning and project management
P2	Works with a built environment professional body withing the standards team
P3	Chartered quantity surveyor working in academia
P4	Specialised in DTs and strategies

The analysis of the interviews is presented in the following section and focuses on the validation of the NRM2 extension while identifying possible further developments of the proposed work.

Validation and benefit of the NRM2 extension for DT systems

The experts P1, P2, P3 expressed the possibility of using the proposed NRM2 extension in their work. There are several reasons for that. For example, the interviewee P1 confirms that using a standard such as the proposed designed NRM2 extended method of estimation for DT systems allows a better understanding and breakdown of possible costs and this would increase the transparency of the DT design and development process.

P3 explains that the proposed approach gives the professionals involved in the cost process the possibility to better understand and quantify what should be covered in DT implementation. Furthermore, P2 explains that implementing standards for estimation for DT systems would be beneficial, and professionals should make sure that this is on their agenda when people are looking at creating new assets, so the DT components would be inserted in the programme and subsequentially costed from day one.

Possible Improvements of the NRM2 extension for DT systems

The experts expressed different suggestions for improving the NRM2 extension too. For example, one participant suggests to expand each sub-component, since there are many things needed to define certain aspects of the DTs. However, for effective pricing of these components it is understandable to have a broader description.

Other participants explains that the proposed extension has covered few or most grounds of the DT concept and this work should not be the end of the elaboration of the designed method and the proposed extension should be taken further and take into consideration DT systems generally and identify the parameters that can be measured. Also, the methods to effectively measure them should be studied.

Additionally, the NRM2 extension interlaps with methods of estimation already existing on BMS systems. However, since a DT system main value is to track data that is currently not tracked, the proposed extension should focus on the data interoperability aspect, the information and where this information needs to be stored as an essential part of the DT system. Finally, understanding the system architecture that needs to be implemented and how to link all the data from different sources should be taken into account, as well as focusing on the two essential aspects of DTs: fidelity and frequency.

Discussion and conclusions

The key objective of this research is to develop a method of estimation for DT for aiding the digital transformation process, and this sheds light on how digital technologies which fit within the DT concept can be effectively costed. In fact, the DT implementations play nowadays a central role in the construction industry digitalisation and, given the wide breadth of applications, represent a significant case of digitalisation in the construction industry.

To address the research gap, we looked into current standards and approaches utilised for DT systems implementation and through the analysis of the theoretical framework we identify some key capabilities: data acquisition, data modelling, data analysis, actuation and curation. These capabilities are analysed from the technological point of view and the enabling items to be estimated are identified. For this purpose, the NRM2 is used, and this aids the development of a method of estimation for the DT system during the phase of design which can be used for tendering. This research has been developed using a mixed evidence-based method and a literature analysis approach.

One of the main benefits is that the proposed method of estimation contributes to creating a standard for the estimation of the DT technological components, which streamlines the budgeting activities and improves the design and value engineering of the system.

Further studies should explore in more depth the DT capabilities and identify the detailed costs of DT systems proposed in the research within the NRM2 extension which includes the unit of measure and the applied pricing method. For example, the cost functions for each of the DT components have not been defined, as well as the total cost function. This would form part of the future development of this research.

Moreover, the last three steps of the design research method should be addressed, these include demonstration, evaluation and communication. Accordingly, the NRM2 extension should be implemented in a pilot design process, so that the results would be evaluated on a real testbed. The validation phase (an additional one to the preliminary validation carried out through interviews with the industry experts) can be carried out using a comparative evidence-based approach, assessing the effectiveness of the proposed method as opposed to the traditional estimation methodologies and through an additional round of interviews.

Also, further studies should explore the possibilities of life cycle costing for the implementation of the system and its financial/economic benefits throughout the life cycle of the building. This would contribute to a better understanding of the costs related to digital transformation.

Energy Modelling and Monitoring

ANALYZING THE ENVIROMENTAL SUSTAINABILITY OF SMART BUILDINGS

Sara Aouichaoui[1], Farina Koller[1] and Niels Bartels[1]
[1]University of Applied Sciences, Cologne, Germany

Abstract

Smart buildings are becoming increasingly important for the construction industry. They are associated with optimization potential for efficiency and therefore ecological sustainability. However, there are currently no studies that can scientifically prove this thesis. Through a comprehensive methodology involving literature reviews, analysis of smart buildings, and expert interviews, the study explores the complexities of achieving environmental sustainability in smart buildings. Emphasizing the importance of standardized definitions, data availability, and collaboration among stakeholders, the paper presents use cases and highlights their impact on the sustainability of a smart building. Furthermore, information for evaluating the environmental sustainability of smart buildings is defined.

Introduction

According to the European Copernicus Climate Change Service 2023 will be the hottest year in the last 125.000 years. Oktober 2023 even sets a record as the warmest month ever recorded, with a global average temperature 1.7 degrees above pre-industrial levels (Schmid, 2023). This underscores the urgency of adhering to the goals of the Paris Climate Agreement, not only in limiting global temperature rise but also in reducing emissions and adapting to climate change (Europäische Union, 2016), (Bundesministerium für wirtschaftliche Zusammenarbeit und Entwicklung, 2023). The building sector, responsible for 40 % of final energy consumption in Europe (United Nations Environment Programme, 2022), plays a crucial role. In Germany, 35 % of total energy consumption goes to buildings, contributing to 30 % of annual CO_2 emissions, with 75 % of a building's carbon emissions occurring during operation (SmartScore, 2021).

To address this, there is a need to reduce energy consumption in existing buildings and enhance the sustainability of new ones. Innovative construction methods and materials, such as 3D printing, wood, clay, and CO_2-reduced concrete, are being explored (Bäuerle & Lohmann, 2021), (Neef, et al., 2020), (Haist, et al., 2023). Simultaneously, the adoption of technological solutions, especially smart building applications, is increasing (Mordor Intelligence, 2023).

Despite the growing interest, there is a lack of comprehensive scientific studies on the ecological sustainability of smart buildings, particularly in terms of user and facility management practices. This paper aims to fill this gap by scientifically analyzing the environmental sustainability of smart buildings.

- Which applications and associated data are necessary for evaluating the ecological sustainability of a smart building?
- What data is available for use in a smart building that goes beyond a classic building atomization and what additional data is required?

This case study was carried out exclusively in the Smart office area, because smart homes have too individual a design, as well as other data protection difficulties. Furthermore, the smartness of other types of buildings has not yet been sufficiently further developed. It will assess optimization potential, consider stakeholders (project developers, owners, manufacturers, and facility managers), and scrutinize data flow within smart buildings, identifying potential interface problems and data losses. The paper concludes with recommendations on calculating the environmental sustainability of smart buildings based on practical experiences and expert insights.

Literature Review and related work

Definition of a smart building

A clear distinction between buildings with classic building automation and smart buildings was drawn up with the help of a literature review. The literature and practical applications lack a uniform definition of a smart building, attributed partly to differing perspectives among project participants throughout a building's life cycle (SmartScore, 2021), (Monterioa Froufe, et al., 2020). As outlined in literature developers emphasize user experience for increased property value, while facility management (FM) focuses on safety and energy savings (Qolomany, et al., 2019), (Li, et al., 2020), (Pašek & Sojková, 2018). To sustain a smart building efficiently and ecologically, there is a need to network stakeholders and establish a unified definition.

Current consensus, based on literature and project analysis, describes a smart building as one equipped with diverse technologies (actuators, sensors, microchips) for data collection, storage, and analysis (Bosch & Deckert, 2023), (Plageras, et al., 2018). According to the (Fraunhofer-Allianz Bau, 2022), smart buildings use automation to enhance physical properties through holistic control concepts and suitable technologies. They integrate existing building automation systems or use autonomous sensor technology installed solely for smart building solutions (Graveto, et al., 2022).

There exist different perspectives on smart building applications. (Bosch & Deckert, 2023) focus on automated, energy-efficient, and sustainable building networking that positively impacts user experience, climate protection, and environmental conservation. (Moretti, et al., 2020) emphasizes optimizing maintenance services in smart buildings.

A comprehensive definition emerges from these perspectives that is shown in Figure 1: A smart building is a digitally connected building with diverse technologies and systems. It aims to enhance user experience and positively impact the three pillars of sustainability. Smart buildings continuously collect real-time data through sensors of the facilities, systems and users. This data is transparently stored, processed, and evaluated, ideally in a cloud and made available to a building management platform. Considering data over the building's life cycle supports optimization, acting as a foundation for new building planning.

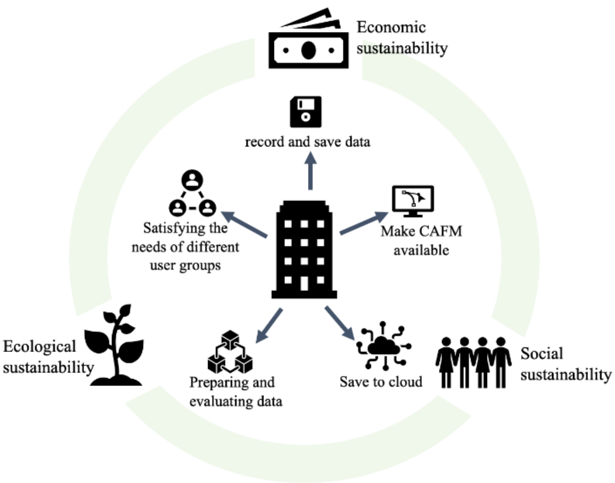

Figure 1: Definition of a smart building

Influence of smart buildings on environmental sustainability

Research in the field of smart building is becoming increasingly important, especially in relation to environmental sustainability. Figure 2 shows the number of scientific publications on the keywords "smart building" and "sustainability" and a continuous increase on Scopus and google scholar between 2018-2023.

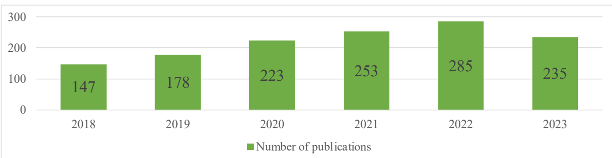

Figure 2: Publication in the area of smart buildings and environmental sustainability published in the years 2018-2023

With the Smart Readiness Indicator (SRI), the European Union provides a basis for assessing the readiness to implement smart components in buildings. However, this does not provide a basis for assessing the sustainability of the building (The European Commission, 2020). Rising energy costs and the need to meet the Paris climate targets (Koch, 2023) mean that companies want to reduce their consumption in office space through energy monitoring (Nulsch, 2023). ISO 52120-1:2021 deals with the influence of building automation and management on energy efficiency (DIN e.V., 2019). This shows a correspondence with the analyzed use cases of a smart building. The standard uses a factor-based method to estimate the influence of energy consumption based on the degree of automation of various functions. Improving the energy efficiency standard according to the standard can lead to significant savings, although previous standards have listed similar factors. In literature it is stated, that smart buildings could save 10 % - 25 % in energy (Fraunhofer-Allianz Bau, 2022), (Fraunhofer-Allianz Bau, 2023), (Jacob & Kukovec, 2022). Annex 81 addresses the fact that the potential of digitalization for the energy efficiency of buildings has not yet been fully exploited. among other things, the project aims to develop software applications with the help of available cost-efficient data in buildings. Semantic standards are defined and an open data platform is required (International Energy Agency, 2023).

Manufacturers promote smart buildings as a driver for environmental sustainability in the building sector, focusing on reduced energy consumption, cost reduction and increased comfort through intelligent optimization systems that adapt energy consumption to occupancy and use. More efficient use of space saves resources and maximizes stakeholders' profits (Siemens Schweiz AG, 2020). In order to evaluate the savings and optimizations of environmental sustainability by smart buildings, an analysis of 23 manufacturers have been conducted in addition to the literature review. The information was taken from product catalogs, white papers, proof of concepts or the companies' websites. Eight of 23 companies indicate potential savings, that vary from 10 % up to 40 %. Some providers regard the energy in general, others differentiate between heating and lighting energy. A few put the savings in heating costs or operating costs at between 30 % and 40 %. One claims to achieve area savings of 30 %. The other 15 companies do not provide any information on savings. The analysis showed 5 major problems in defining the environmental sustainability for smart buildings:

1. No information is provided on the initial values (e.g., planning or previous years of operation) or the basis for calculating the savings,
2. predominantly no information on whether the savings relate to thermal or electrical energy,
3. the number given cannot be substantiated, as generalized statements about CO_2 savings are often made or an increase in the users' sense of comfort is suggested, as well as falling personnel costs due to a healthier environment,
4. the focus is on long-term savings potential rather than short-term added value and
5. changes in the use or operation of the property, deviating conditions in facility management and other relevant factors on the technical side are not mentioned.

None of these problems will be solved by special solutions in showcase buildings. In order to make the building sector more sustainable, solutions are needed for the building sector as a whole.

Methodology

Based on the literature review (Literature Review and related work) on "smart building" and "environmental sustainability" keywords was conducted using databases like

Google Scholar and Scopus, the revision of the research gaps is carried out in three steps, that are shown in Figure 3.

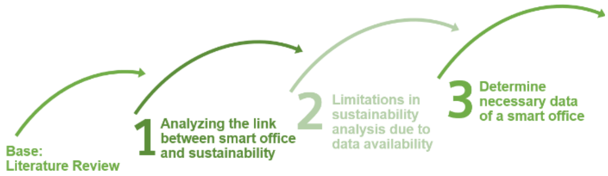

Figure 3: Methodology of this paper

Step 1 analyzed the current link between sustainability and smart buildings in Practice. Therefore, firstly 15 Case Studies of Smart Buildings in Central Europe were analyzed. Afterwards, the results were validated by guided interviews with 67 experts provided qualitative and quantitative insights. By doing so, the use cases, that affect the ecological sustainability of smart buildings, were evaluated.

Step 2 outlines limitations in sustainability analysis due to data availability. Hereby, the challenges highlighted in the expert interviews (e.g., data availability) were first summarized and discussed. Based on that, the data of 4 smart buildings, that were provided by the Facility Management and the building owner, were analyzed. In addition to that, the loss of data throughout the data processing from data collection to data usage is evaluated based on the case studies and further expert interviews.

Due to the lack of complete data, that could proof the sustainable impact of smart buildings, recommendations for necessary smart building data are made in a final step (Step 3).

Step 1: Analysis of the environmental sustainability of smart buildings in practice

In order to evaluate the environmental sustainability 15 Case Studies were analyzed. Furthermore, 25 guided interviews were conducted with participants from 67 requested companies in asset and facility management (AM & FM), general contracting (GC), hardware and software manufacturers (manufactures) in building services, engineering, planning (P), project development (PD), and owners (O) (Figure 4) in order to validate the results of the Case Study analysis.

The companies were selected based on literature, project analysis, and smart building experience. Only 25 companies could provide insights into the link between smart buildings and sustainability, resulting in a 37 % response rate. Interviews took place between April 17 and June 30, 2023, either via Teams or on-site, with four companies also submitting written information.

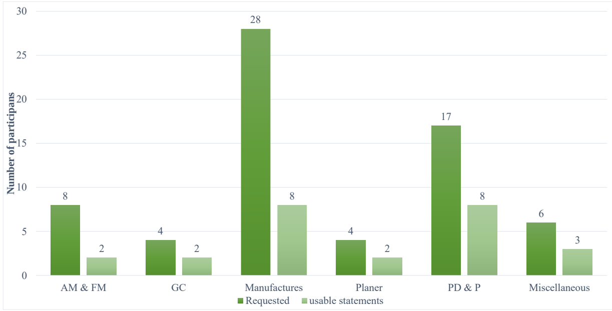

Figure 4: Participants' structure of the expert interviews

The expert interviews were based on the analysis from the basic analysis and the use cases of smart buildings, which were evaluated in workshops with experts. Drawing on existing knowledge, freely available content from implemented smart buildings, planning documents, and input from Central European smart building planners, use cases were clustered and evaluated for their environmental sustainability impact. A total of 64 use cases were evaluated.

Evaluation of the use cases of smart buildings based on Case Studies and interviews

The analysis of 15 Smart Offices in Germany and Central Europe identified 64 use cases. Due to expert interviews those can be categorized into seven main areas. In addition, the potential influence of these on the three pillars of sustainability was identified. Examining the implementation rates of these use cases in smart offices, Figure 5 illustrates their distribution. The further out the use cases are placed, the more frequently they are implemented (Percentages in Figure 5). Notably, 34 % of all use cases impact environmental sustainability (shown in bright green), while 52 % influence economic sustainability, and 72 % impact social sustainability (shown in dark green).

The dominance of energy supply (82 % of use cases) and water supply (100 % of use cases) is evident in their substantial influence on the environmental sustainability of buildings. Only 36 % of the environmentally sustainable use cases were implemented in at least 50 % of the analyzed buildings, challenging the notion that smart systems are primarily implemented for environmental reasons. Most use cases affecting environmental sustainability (72 %) were implemented in less than 33 % of the smart buildings. Further examination highlights that use cases related to information management, user experience, and building security significantly impact social sustainability and user comfort. Over half (56 %) of these use cases were integrated into more than 33 % of the buildings, indicating a predominant focus on user satisfaction and experience rather than increasing environmental sustainability.

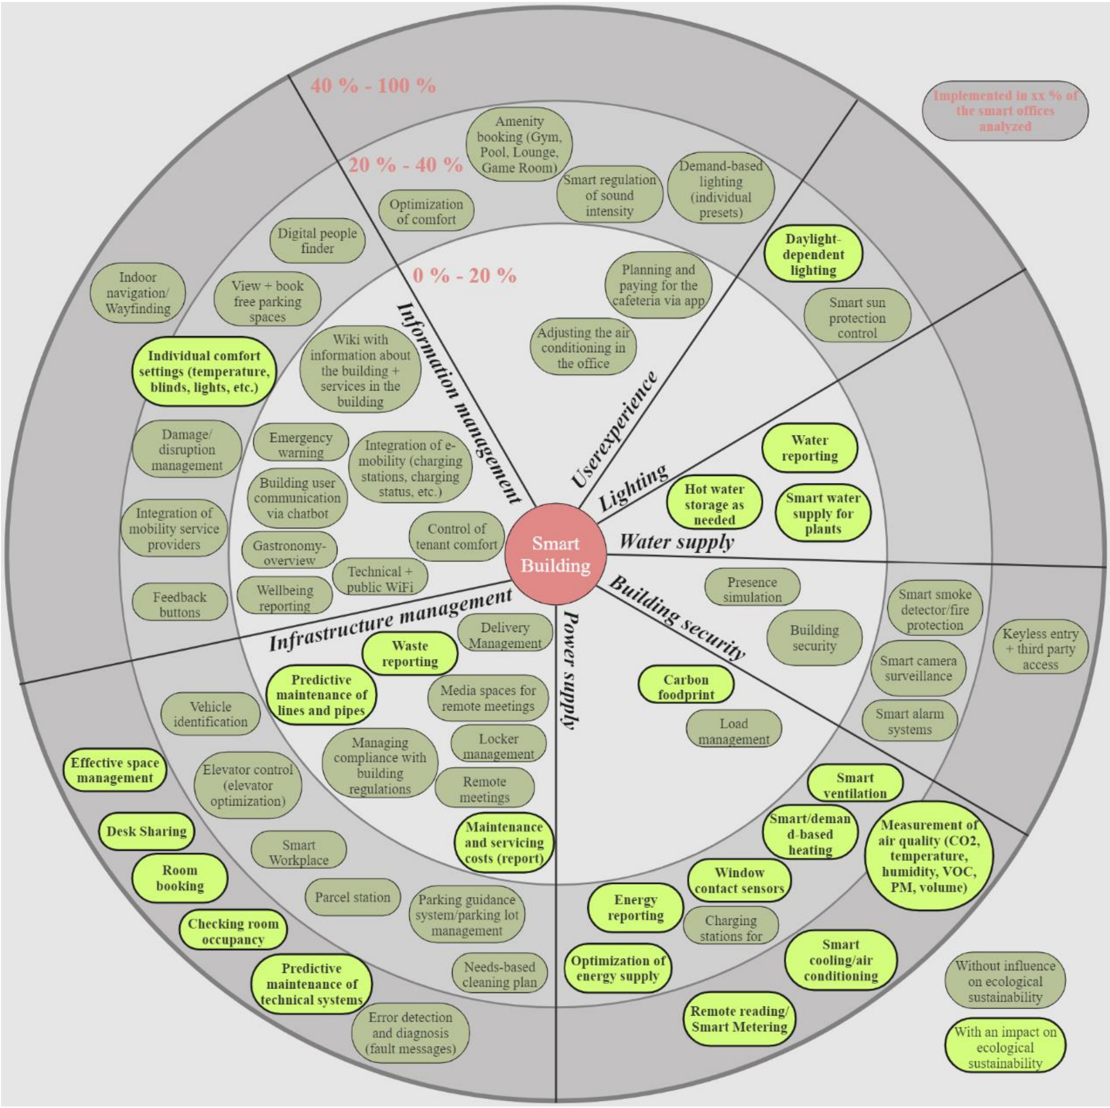

Figure 5: Illustration of the use cases of a smart building depending on the areas of application and illustration of the influence on environmental sustainability, as well as the frequency of use cases in realized smart buildings

Detailed expert interviews demonstrate that environmental sustainability is regularly not the primary objective of smart buildings but emerges as a by-product. Figure 6 the distribution of use cases impacting environmental sustainability, as well as their combinations with social and economic sustainability. Only 6 % of use cases exclusively impact environmental sustainability, while 61 % influence both environmental and economic sustainability. This dual impact is often due to the intention to operate buildings more cost-effectively, with reduced energy consumption correlating with improved ecological sustainability. Additionally, 33 % of use cases impact both social and environmental sustainability, reflecting the interconnected nature of these factors. This reiterates that the influence on ecological sustainability is typically a secondary outcome of smart building implementations.

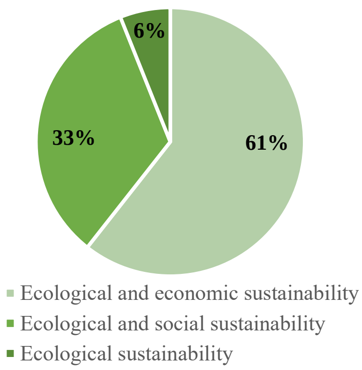

Figure 6: Percentage distribution of use cases with influence on the three pillars of sustainability

Summary of the results and critical discussion

Based on the statements of the experts, 4 trends can be identified in which the use of smart buildings can lead to an optimization of ecological sustainability:

1. several experts confirm that the increase in mobile working that occurred during the Corona pandemic resulted in a high vacancy rate. This increased the importance of and interest in use cases that optimize the use of space, such as workplace booking or space management. This allows space savings to be achieved, which can reduce both grey energy and energy in operation, as space is used more optimally.

2. At the same time, these are aimed at environmental sustainability through side effects such as needs-based heating or air conditioning.

3. Sustainable management of buildings can also be achieved through the shared use of resources, such as meeting rooms, cars, workstations, etc.

4. an analysis of consumption values and the presence of people can contribute to optimized energy use (e.g., by reducing the use of space in the company).

Expert interviews reveal that smart building use cases can enhance environmental sustainability, but there is disagreement on whether smart functionalities are essential for sustainable construction and operation. Some argue that sustainable practices can be achieved through optimal design and material choices alone, while others emphasize the importance of needs-based regulation and suggest additional energy savings through sensor and hardware utilization. The following section provides detailed insights into these perspectives. The experts also assert that a building's operation can be made more ecologically sustainable through analyses and subsequent optimization of energy consumption or space utilization (Figure 7). This definition of the functionality levels can also be found in the definition of the SRI. However, insufficient information is available on the data basis for calculating these savings, with only one interviewee from the manufacturer group mentioning the starting point as the planned energy demand of the building. It is unanimously agreed among the experts that smart functionalities serve as optimizations rather than remedies for planning errors.

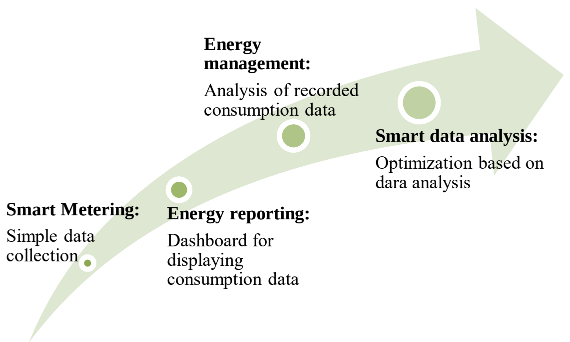

Figure 7: Exemplary optimization levels of the use cases

Step 2: Analyzing limitations of the sustainable smart building due to data availability

This section summarizes expert assessments of the initial situation regarding data availability in the real estate sector. Afterwards, the data basis used by the experts in their own companies will be examines. Finally relevant building data from the study that can be used to measure and assess the environmental sustainability of a building is listed.

Case Studies

6 % of the requested experts were able to provide data from their smart buildings. The remaining respondents referred to data protection or were unable to provide data for other reasons. The received data sets were incomplete or not meaningful. For two buildings, the data could only be provided monthly and for one building only annually. It was not possible to clearly identify the system boundaries to which the data refers. In addition, in three cases, information on the building was missing. Therefore, it was not possible to analyze the sustainable operation of an actually implemented smart building. As a result, the savings claimed by the experts cannot be validated. For this reason, data and their collection interval, which are necessary for the evaluation of the building operation, were identified and summarized in Table 1.

Initial situation of the real estate sector regarding data availability according to the experts

A smart building requires the effective use of data stored in the cloud to promote environmental sustainability. It is necessary to capture data from the building management system, integrated use cases and the entire life cycle of the building. All data (e.g., building model, consumption data, attendance data, FM data, BMS data) from the building must be available over the entire life cycle in order to be able to derive optimization potential from the data. 20 % of experts emphasize that large FM companies often prioritize functionality and user well-being, while building sustainability is neglected. 50 % of manufacturer experts report impairments due to manual interventions in automated processes. Furthermore, two experts noted that the operators often do not have the necessary in-depth knowledge of all the processes and functions of the building and also do not have the capacity to operate a building in a technically professional manner. Another expert criticized the fact that the owners have no need to make the management of the building more sustainable, as the tenants bear the energy costs. Continuous optimization for sustainable operation moves into the background. Some owners have only shown an interest in sustainable building operation since the changes in the real estate industry, as tenants now bear the energy costs.

Current data basis of the experts

Figure 8 shows the results of the expert interviews on the use of the data collected in smart buildings and highlights the data flows and losses. It was interrogated whether data on building operation is recorded and if this data is used

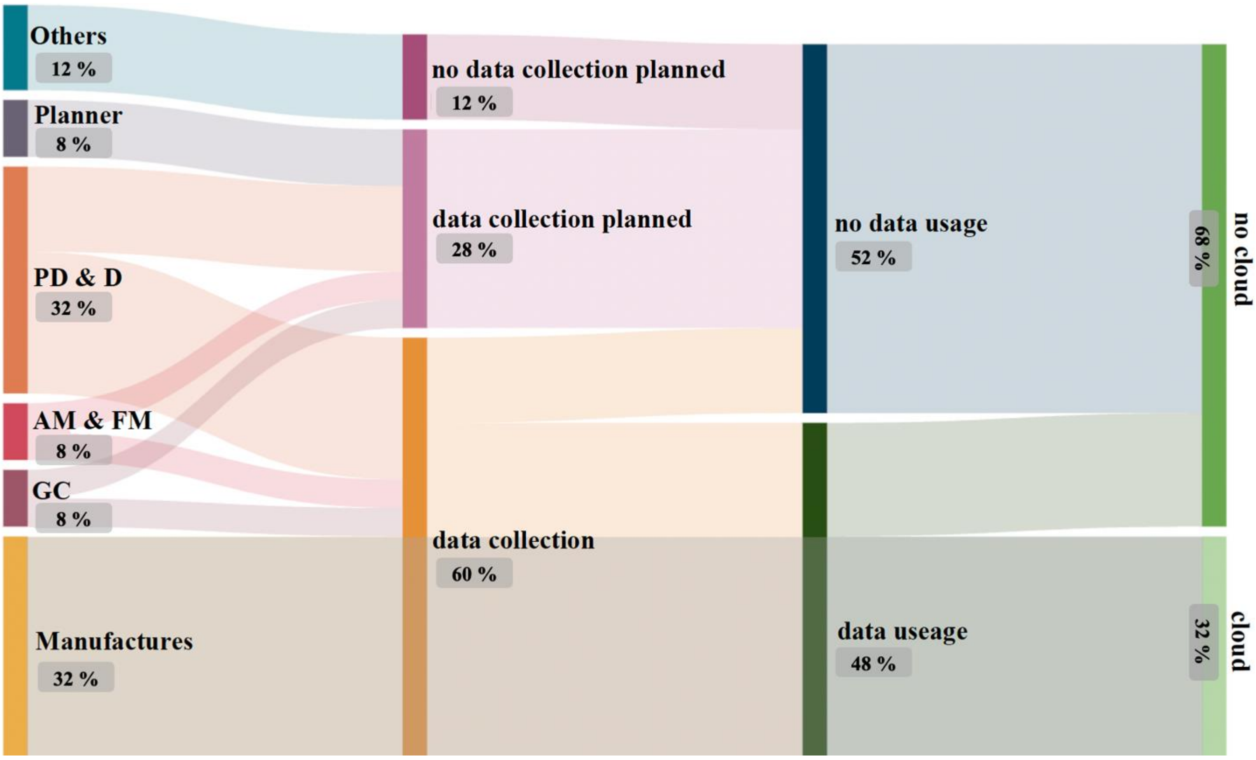

Figure 8: Illustration of the current data basis based on the expert interviews

for further purposes. The status of cloud solutions for data storage was also determined.

60 % of the companies surveyed collect building operating data (marked in orange), either directly by owners, FM or third-party providers. 28 % plan to collect data, while 12 % have no plans to do so.

Of the companies collecting data, 20 % do not use the data further and the storage locations are unclear. The remaining 80 % use the data for FM support, plant optimization or sustainable operational control. This corresponds to 48 % of all companies surveyed, with 75 % of these data-collecting companies being manufacturers. Only 62 % of the project developers and owners surveyed receive data from manufacturers, which is merged in PowerBI dashboards. A proprietary building operating system is rarely used. Over 50 % of experts do not use any building technology or energy-related data for optimization in their companies. Only 32 % of interviewed companies store data centrally in a cloud. However, they all belong to the group of manufacturers who sell the clous as part of their portfolios This means that it is not possible to draw any conclusions as to whether the relevant players (FM, building owners, etc.) use the data centrally for long-term analyses and evaluations of optimization scenarios.

Difficulties in data availability

The aim of this paper is to compile relevant data for the uniform assessment of smart buildings in terms of environmental sustainability. The following section presents the necessary data basis. In the validation phase following the interviews, only four companies provided data on their smart buildings, which was largely implausible and incomplete. Due to a lack of data quality, no conclusions could be drawn about the operation and sustainability of the buildings. Data protection issues and concerns, particularly in relation to the General Data Protection Regulation (GDPR), also prevented 73 % of experts from releasing data. Works councils were against use cases that collect personal data, such as access controls, due to concerns about employees' privacy rights. The debate on data protection versus sustainability remains open. Two experts criticized the lack of availability of data for optimization and research purposes, while one manufacturer considered anonymized provision of customer data in the future but pointed to limited resources.

Step 3: Definition of Relevant Data for assessing environmental sustainability

The results of the expert interviews and available data show the current problem in the building sector: data availability. Data is regularly not recorded and stored sufficiently over a long time by the building management system. Data failures go unnoticed and even existing data is not used optimally. A sufficient data basis is crucial so that the collected data can be automatically processed and made available to users, asset managers and other stakeholders in a clear and concise manner. Only in this way can the data be used for optimization and have a positive impact on environmental sustainability. The building management system often records various data over a period of time, including supply and return temperatures, control signals and status messages from technical components. This data can already indicate major errors in the regulation and control system.

To assess the sustainability of smart buildings, the experts listed implemented use cases and provided consumption data for heating, cooling and electricity at quarter-hour intervals. The inclusion of occupancy data, such as the number and type of occupants, was considered crucial. The information requested included building area, type of use, number of employees, occupancy data, metering concepts, floor plans, heating/cooling systems, ventilation and sensor infrastructure. Based on these criteria, relevant data for the environmental sustainability analysis in smart buildings is compiled in Table 1.

Table 1: Data basis for the sustainability assessment of a smart building

Nature of the data	**Description**
Energy consumption data (heating, cooling and electricity) of the building	
Consumption data for the entire building, individual parts of the building or rental sections - General, technical and tenant electricity - Heating/cooling consumption of the respective rental areas, if applicable meeting and conference rooms recorded individually	Ideally, consumption data should be recorded on a quarter-hourly basis and broken down into individual building sections. Smaller-scale recording enables more precise monitoring and must be selected according to the type of use of the building. *[kWh]*
Emission factor of the respective energies	CO_2-equivalent data for different energy sources according to the Law on Energy Efficiency. To compare the type of energy supplier in different buildings. *[gCO_2e/ kWh]*
Outdoor temperature	To classify the amount of energy consumed. Ideally every 15 minutes for consumption *[°C]*
Planning documents	
Average demand of Energy	Comparative value for checking the operation. This must not be exceeded. *[kWh/ m²a]*
Building area or individual rental space	For consumption data of individual sections, in each case with details of the gross floor area. Allocation and comparison of the different areas. *[m²]*
Type of use	List of the types of use in the building (office, canteen, daycare center, fitness studio, etc.). Relevant for assessing the energy consumption of the smart building as such. As well as for the comparison of other smart buildings by type of use.
Heating and cooling generation systems, air conditioning systems	Information on the type and output of the systems. To classify the energy requirement depending on the respective energy source. As well as for checking the control behavior. *[e.g. kW]*
Building automation and smart building	
Data points of the different systems	Type and number of data points of the technical building systems installed in the building
Individual room control	Zone size incl. number and type of connected data points
Fault message forwarding	Information on the process chain in the event of a fault message from a system or system component. Not directly for comparison or evaluation of ecological sustainability, but decisive for optimization potential of the systems.
Metering concept	Necessary for the allocation of consumption data.
List of implemented use cases	Incl. description, for assessment of smartization.
Data storage	Information on the duration of data storage and storage location to ensure data availability for the analysis of the building.
Sensor infrastructure	Type and number of sensors or concepts regarding the installed sensors (brightness, occupancy, temperature, air quality such as CO_2, Bluetooth beacons), to assess smartization.
Operation	
Occupancy data	Information on m² per person, as well as time-related information on the use of the building area. Is required to assess the energy consumption. *[m²/n; n/h]*
Number of employees	For comparison with other smart buildings *[n]*
Evaluation of the use cases	Evaluation of the frequency of use of different use cases. To identify the optimization potential regarding the use of the building's Smartness.

The identified essential data for evaluating building operation provides a basis for analyzing smart buildings in terms of their sustainability. This database must be validated in further studies.

Conclusion and recommendations for action

The analysis relies on the standardized definition of a smart building established in this paper across different building types. The clustering of use cases serves as a common foundation for assessing potential impacts on environmental, economic, and social sustainability. Currently, ecological sustainability is often considered a by-product of improved economic or social sustainability. To enhance ecological sustainability, more dedicated ecological use cases need implementation. It's important to note that technological advancements may introduce new use cases for smart buildings.

However, the analysis reveals the incompleteness and poor traceability of provided data, particularly concerning energy consumption. Technical and data protection reasons hindered obtaining further information on data classification, occupancy figures, outdoor temperatures, or measurement concepts, rendering the database unreliable. Consequently, results were supplemented with expert interviews, and strategies for future data collection were developed.

The study's limitations include the exclusive use of smart offices from Central Europe and a lack of representation from companies outside Europe. Additionally, the short lifespan of the smart buildings studied suggests that operators may lack a holistic understanding of building functions and processes. The study does not address the embodied carbon of components like sensors, actuators, and cables, posing a need for comprehensive assessments. The study highlights potential for further investigations, particularly regarding the embodied carbon of data storage throughout a building's life cycle.

The identified essential data for evaluating building operation provides a basis for analyzing smart buildings in terms of their sustainability. To validate the defined data basis, real buildings must be monitored over an extended period. Potential increase in CO_2 emissions from additional hardware and data storage should be considered. A comparison with similar buildings lacking smart implementations can provide valuable insights.

BETTER URBAN MANAGEMENT: A SYSTEMATIC REVIEW OF MULTI-SCALE DIGITAL MODELLING

Feng Guo[1], Ling Ma[1]
[1] Huazhong University of Science and Technology, Wuhan, China

Abstract

Digital modelling has significantly progressed. Many scholars have reviewed and summarized the research of digital modelling. However, the reviewer needs to consider the practical applications of digital modelling at different scales. Multi-scale digital modelling (MSDM) refers to digital models that contain different levels of geometric or semantic details. This paper presents a systematic literature review (SLR) of MSDM. Distributed energy generation is one of the most worthwhile research directions. In the future, distributed energy generation systems - energy storage systems - and buildings or urban infrastructure should be interconnected based on MSDM.

Introduction

Digital modelling of buildings and cities is becoming an important research topic. Digital models of buildings, usually referred to as Building Information Models (BIM) or 3D building models, are detailed, accurate, and visual representations of buildings. BIM can be utilized across all stages of a building's complete lifecycle, including design, construction, operation, and maintenance (Qiu et al., 2021). In the design phase, BIM facilitates a more profound understanding among all stakeholders of the building's details and overall design compared to traditional 2D drawing models, allowing for the early identification of potential design issues such as clashes in piping or structural elements (Huh et al., 2023); in the construction phase, BIM aids in visualizing construction progress and enhancing on-site safety management (Tu et al., 2021); in the operation and maintenance phase, the energy consumption (Kamel and Kazemian, 2023) and carbon emissions (Lu and Deng, 2023) generated during the use phase of a building can be estimated from the site data collected by BIM and devices like sensors. A key benefit of BIM and equivalent technologies is their object-oriented nature, which ensures that models accurately represent physical and functional characteristics and encompass objectified relationships among building components. Despite its benefits, BIM is mainly only used in the design phase (Tu et al., 2021). The main reason is that BIM is required to carry different information for different phases, and too much useless information will reduce users' willingness (Wang et al., 2022). Therefore, it is necessary to develop BIMs containing different information or to automate the addition or subtraction of BIM information for different usage requirements.

Digital models of cities usually referred to as City Information Models (CIM) or 3D city models, which need to consider topographical data such as mountains, rivers and buildings and infrastructure (Xia et al., 2022). Souza and Bueno (2022) have shown that CIM contains Geographic Information System (GIS) data and BIM data, as well as data collected by the Internet of Things (IoT) and sensors. It enables automatic management of urban information and predictive reasoning about urban problems. For example, as different regions and buildings in a city have different energy demands and consumption (Camero and Alba, 2019), CIM can help predict energy-associated problems ((Xia et al., 2022) (Weil et al., 2023)). Although CIM can present a wealth of information, CIM faces a similar problem as BIM: they both carry a wealth of information, which makes users who only need a specific piece of information reluctant to invest additional time and resources to get the information they need from it. In other words, the development of BIM/CIM with different information or the ability to automatically add or subtract information from BIM/CIM is a real need for most users. In BIM/CIM, 3D geometric models are critical primary data. To improve the user experience and meet different business requirements and application scenarios, developing digital models with different geometric levels or graphical simplification may be an effective way.

The same Digital models may have different levels of detail (LoD) in different application scenarios. LoD refers to the representation of a 3D model with different data information, mainly concerned with the geometric details of the graphics. In BIM/CIM, there is a similar concept of LoD, but it is not limited to graphical rendering but also includes other information (Deng et al., 2016). In the commonly used CIM data exchange format City Geography Markup Language (CityGML), LoD is not only the complexity of the geometrical level of the city model but also includes the complexity of the semantic information (Kolbe et al., 2005). The concept of LoD also exists in BIM. However, the current level of development (LOD) is more widely used than LoD, which was developed by the American Institute of Architects (AIA) as an improvement of LoD and started with five levels from LOD 100 to LOD 500 (Abualdenien and Borrmann, 2022), corresponding to the five phases of conceptualization, approximate components, exact components, construction, and completion. The BIMForum has further improved the AIA definition by developing a new LOD350 level and publishing the LOD Specification. In addition to defining LoDs with expert knowledge, it is also possible to adjust the LoDs of the model using some software, such as Blender and Unity, which can modify graphics details. Fig. 1 shows the result of representing the exact Monkey in Blender with a different number of surfaces.

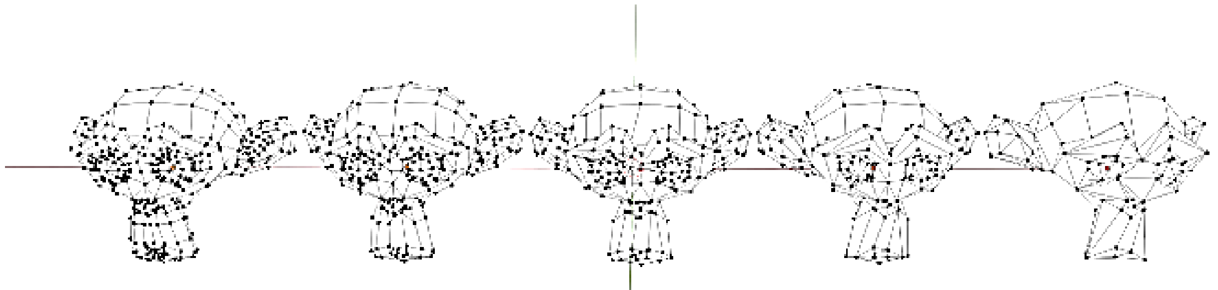

Figure 1: Blender generates a Monkey with different numbers of faces

Although some standards for LoDs exist, there still needs to be more clarity in understanding the information required for LoDs in different countries and organizations, especially concerning geometry. The main reason is that semantic information can usually be normalized into a set of attributes, but systematically examining the geometric details of a model, developing appropriate criteria to classify the hierarchy of geometries, and applying them to specific models is very difficult (Abualdenien and Borrmann, 2022). In addition, integrating the models of different LoDs into a city model is also a challenge. Table. 1 shows the LoD of BIM defined by AIA and the definition of LoD by CityGML

Table 1: LoD Definitions for BIM and GIS

LoD of BIM	LoD of GIS
LoD 100: Information on building height, area, and volume for conceptual design	LoD 0: Digital Elevation Model (DEM) and Digital Orthophoto Map (DOM) for regional landscape representation scale
LoD 200: Approximate information on generic elements for preliminary design	LoD 1: Block models at the city and regional representation scale
LoD 300: Detailed information on specific components for detailed design	LoD 2: Basic models at the district and street representation scale
LoD 400: Complete construction and installation information for the construction design	LoD 3: Standard models for representative building exteriors
LoD 500: Information on structural components corresponding to the as-built design	LoD 4: Advanced models for representative building interiors

Similar to this review, many scholars have reviewed and summarized the literature on BIM, GIS, Urban Digital Twin (UDT), and other themes related to digital modelling. Table. 2 shows some of the representative literature.

Table 2: A representative collection of literature reviews related to BIM/GIS/UDT

Articles	Main Contents
Wang et al., (2019)	It provided a review of BIM-GIS integration in sustainable built environments.
Jiang et al., (2021)	It identified recent advances in DT in civil engineering and made recommendations for future DT developments.
Khan et al., (2022)	It highlighted the challenges and future directions of multiscale modelling for megacities and intelligent cities.
Kamra et al., (2023)	It summarised techniques for lightweight city reconstruction and indicated future research directions.
Weil et al., (2023)	It summarised the main challenges and unresolved issues related to the implementation of UDT.

Compared to the representative literature review in Table. 2, this SLR focuses on the MSDM for buildings and cities. With the rapid development of information technology and the further expansion of urban boundaries, the demand for MSDM will skyrocket(Abualdenien and Borrmann, 2022). Therefore, an SLR is needed to inform scholars of the current research gaps on MSDM and more accurately capture future research priorities.

The rest of the paper follows: Chapter 2 introduces the methodology applied, describing the SLR protocol.

Chapter 3 shows the results obtained by SLR. Chapter 4 discusses the inspirations gained and points out future research priorities. Chapter 5 summarises the whole paper and further highlights the contributions made in this SLR.

Methodology

Searching database and keywords

The literature covered in this SLR is at the intersection of civil engineering and computer graphics. Since computer technology requires high timeliness and many scholars will publish their papers at conferences, this SLR needs to cover conference and journal papers. Four academic databases, ACM Digital Library, IEEE Xplore, Scopus, and Web of Science (WOS), were selected for searching. The ACM Digital Library and IEEE Xplore are critical academic databases for computer science, containing many conference papers and some journal papers related to computer graphics (Cheng et al., 2022). Scopus and WOS are more comprehensive in their coverage of the subject areas and contain more abundant journal papers (Srinivasan and Yadav, 2023) and, therefore, serve as a supplement to the ACM Digital Library and IEEE Xplore.

After determining the search database, this section will identify the search keywords. Considering that the core research question of this SLR is "Research on Building/City MSDM," this SLR divides the required keywords into two parts. Fig. 2 shows the complete search formula (four databases use a similar search logic).

Building modeling

(“ifc” OR “industry foundation class*” OR “bim” OR “building information model*” OR “building model*” OR “building digital twin*”)
AND
(“Multiscale” OR “lod” OR “level of detail*” OR “log” OR “level of geometr*” OR “loi” OR “level of information”)

City modeling

(“citygml” OR “city geography markup language” OR “cim” OR “city information model*” OR “cit* model*” OR “urban* model*” OR “town* model*” OR “cit* digital twin*” OR “urban* digital twin*” OR “town* digital twin*” OR “3D GIS” OR “3D geoinformation”)
AND
(“Multiscale” OR “lod” OR “level of detail*” OR “log” OR “level of geometr*” OR “loi” OR “level of information”)

Figure 2: Schematic diagram of the used search formula

Literature screening criteria

After reading the title-abstract-keywords of each piece of literature, literature duplicated or did not meet the research objectives was excluded, and the detailed literature screening criteria were as follows.

(1) Removing literature whose form of publication is not an article or conference paper (published as a book, magazine, etc.); (2) Removing literature whose language of publication is not English; (3) Removing literature in apparently unrelated subject areas (e.g., Nursing, Veterinary, Dentistry, etc.); (4) Removing literature that is purely theoretical, purely conceptual and not focused on digital modelling; (5) Removing duplicates. After obtaining all the powerfully relevant literature, further reading the full text and delineating the literature at both cities/buildings’ scales. Define the building scale as a single building or a component within a building and the city scale as multiple buildings or the integration of BIM with GIS.

Extracted information

After obtaining the required literature, further reading of the full text extracted more detailed information. The extracted information included the primary statistical information data of the literature. The following 12 categories of information were extracted: authors, affiliation of the first author, country of the first author's affiliation, date of publication, name of the journal or conference, keywords, purpose of the study, software or tool used, source of the data, format of the data, methodology of the study, and results of the study.

Results

Overview

Firstly, the initial search results were IEEE Xplore (123), ACM Digital Library (1316), Scopus (1655), and Web of Science (787), with a total of 3881 pieces of literature retrieved. Secondly, based on the screening criteria, 3881 pieces of literature were refined, resulting in 452. Then, the full text of 452 pieces of literature was carefully read, resulting in 45. Finally, the literature was divided according to the definitions of building scale and city scale. Twenty-four pieces of literature were obtained for the building, 21 for the city.

Research themes

Fig. 3 shows the application scenarios for city/building MSDM. In City management, there are main eight application scenarios. For Urban Renewal Synchronization, Qin, (2014) detected changes in the LoD2 building model using satellite-based stereo images from different dates. For Energy Demand Simulation, Nouvel et al., (2017) investigated the impact of data quality, such as geometry and semantics, on SimStadt's estimation of heating demand. The LoD1 model can reliably estimate the heating demand of an area, and the LoD2 model can reliably estimate the heating demand of a single building. De Jaeger et al., (2018) quantified the geometric and energy characteristics differences between the five variants of LoD1 and LoD2. It investigated the availability of LoD1 and LoD2 and the impact of building geometry in regional energy modelling. For Energy Consumption Simulation, Johari et al., (2022) analyzed the impact of LoD on energy use in different types of multifamily residential buildings. The effect of LoD was negligible in heating seasons, whereas it was significant throughout the year. The deviation between LoD1 and LoD3 was as high as 9%. For Solar Energy Simulation, Nahon et al., (2013) argued that using adaptive LoD speeds up calculations and ensures accuracy. Besuievksy et al., (2014) introduced a flexible LoD system that allows the user to specify the geometric hierarchy of geometric models for solar simulation. Besuievksy et al., (2014) estimated the annual solar irradiance of a building's roof using Monte Carlo simulation and conducted uncertainty analyses in different LoD models. Besuievsky et al., (2018) proposed a new LoD strategy that automatically detects and preserves the geometries (e.g., roofs) that affect the solar simulation. It simplified the rest of the geometries. Machete et al., (2018) evaluated the impact of the urban environment on the exposure of building roofs and facades to solar radiation by combining a 3D GIS with a solar radiation tool and using two different modelling approaches (2.5D and 3D methods). Peronato et al., (2018) simulated the solar irradiance of 109 buildings at different spatial and temporal granularities using the LoD2 model. Saretta et al., (2020) defined the LoD2.5 model to estimate the BIPV potential of a city containing facades. Han et al., (2022) predicted the regional power potential by analyzing the variation of shading effects between the LoD1 and LoD2 models. Krapf et al., (2022) extracted the roof superstructure from aerial imagery using deep learning, which can improve the solar simulation's accuracy. Yan et al., (2023) reconstructed three-dimensional buildings from high-resolution satellite imagery using a detail-oriented deep learning method and estimated the solar power potential. For Climate Simulation, Chen et al., (2020) cited 16 LoD models defined by Biljecki et al., (2016) for climate simulation.

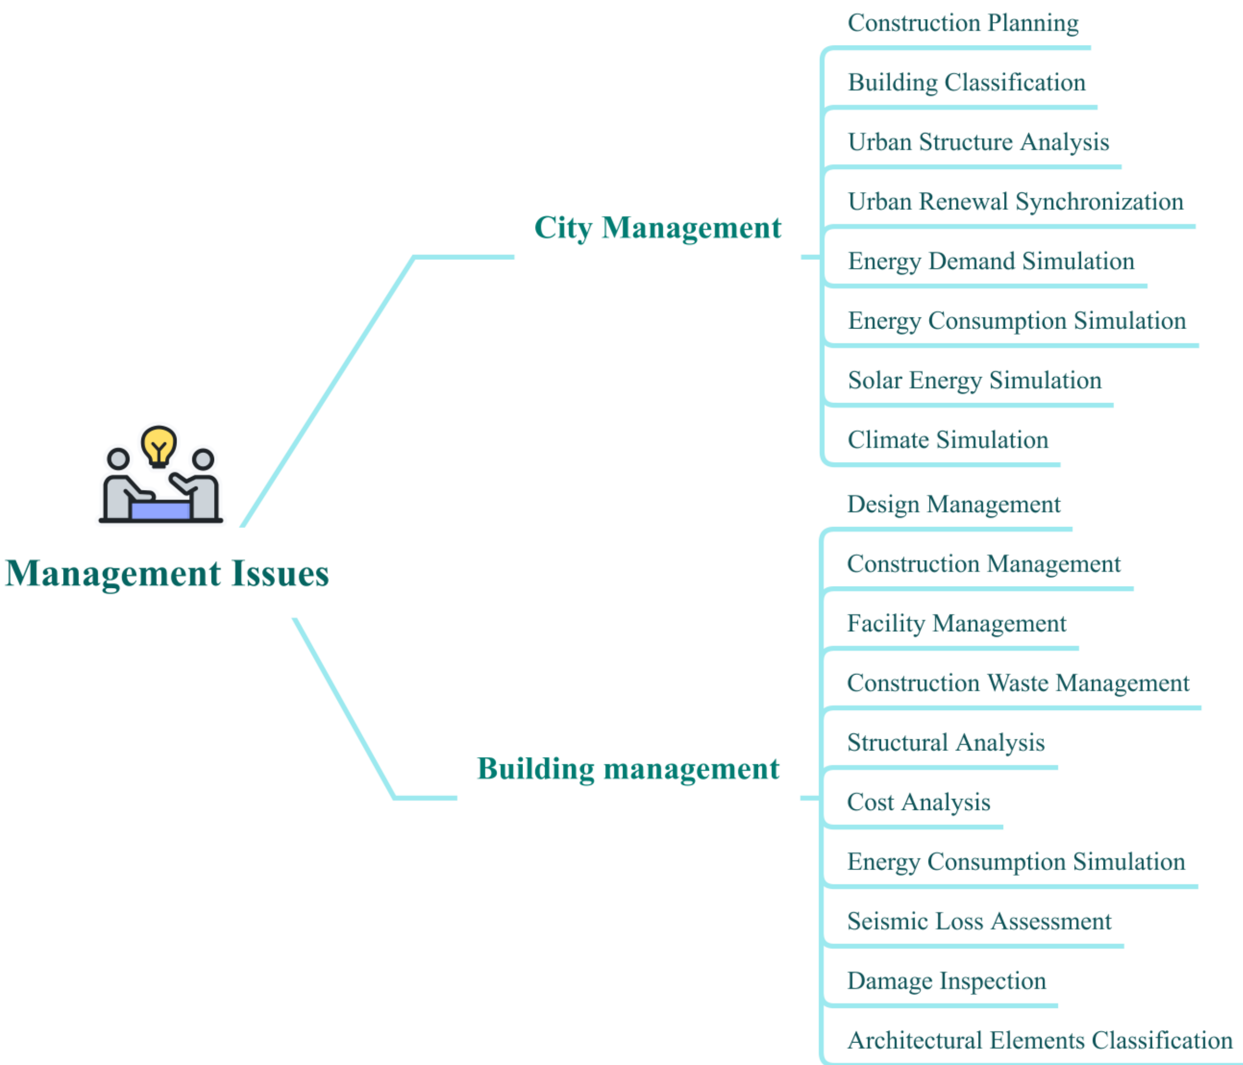

Figure 3: Application scenarios for city/building MSDM

In Building management, there are main ten application scenarios. For Design Management, Leite et al., (2011) evaluated the effort required to generate BIMs with different LoDs and the impact of LoDs on design coordination, such as electrical and plumbing (MEP). Huang et al., (2022) extended IFC to develop BIM models of metro stations with multiple LoDs, which can cope with different scenarios. For Construction Management, Han et al., (2015) enhanced the 4D BIM with lower LoDs to provide visual construction progress assessment for some projects. For Facility Management, Dias and Ergan, (2016) developed LoDs for facilities management. For Construction Waste Management, Sanchez et al., (2021) developed methods to automatically determine parameters that can be disassembled and defined BIM models and parameters for disassembly. For Structural Analysis, Briggen et al., (2009) used Computational Fluid Dynamics to predict Wind-driven rain volumes, concluding that façade geometric detailing significantly affects localization. Gonizzi Barsanti et al., (2023) obtained appropriate geometric detailing level models from the point cloud data, which can be used directly in finite element calculations. For Cost Analysis, Wood et al., (2014) enabled the automatic calculation of design costs by matching building material data with cost data on different LoDs. For Energy Consumption Simulation, Geyer et al., (2018) proposed a multi-LoD modelling approach combined with machine learning algorithms to predict energy performance. Malhotra et al., (2019) compared different LoDs and determined the LoDs required for heating load simulation. Singh and Geyer, (2020) analyzed the extent to which design parameters influence energy consumption prediction. It identified the information required for each level in a multi-LoD. Mediavilla et al., (2023) developed a methodology based on graph techniques for using multiscale BIM for energy analysis. Jung et al., (2023) proposed that LoD350 was suitable for modelling the energy performance of actual buildings. Xu et al., (2023) proposed a new LoD2 (LoD2ES) for energy simulation. For Seismic Loss Assessment, Xu et al., (2019) evaluated earthquake damage using BIM with different LoDs. For Damage Inspection, Pantoja-Rosero et al., (2023) constructed LoD3 BIM models for building damage assessment. For Architectural Elements Classification, Koo et al., (2021) classified IfcDoor and IfcWall using Multi-view CNN and PointNet. Abualdenien and Borrmann, (2022) proposed a framework for analyzing and checking the LoG of BIM.

In City/Building Management, energy issues are hot research themes. Scholars try to use different LoD models, combine different frameworks, and use different methods to predict the energy demand, consumption, and solar power generation potential. Scholars have already obtained valuable research results. However, many issues still need to be fully resolved due to the excessive number of factors and the complexity of the problem. There will remain a topic worthy of in-depth research.

Implication

Current researches

MSDM is for a better solution to practical problems. By this paper, it is clear that MSDM can serve all stages of the whole life cycle of a building, solving problems in all aspects of urban construction and maintenance, which contribute to the sustainable development of cities. However, there are still the following limitations in the current researches.

Much of the current literature on the application of MSDM to city management focuses on problems related to building groups. Although the problems addressed are relevant to individuals and societies, the boundaries of research should be further expanded. Scholars need to consider infrastructure and management issues further. MSDM is a substantial database for solving all kinds of problems in the city and society.

Future directions

MSDM has to serve practical problems. The above limitation is a direction that deserve research in the future, but the current most worthwhile research is to use MSDM to solve urban energy-related problems.

Excessive use of non-renewable energy sources (such as fossil fuels) may cause environmental and social problems. Widespread use of renewable energy in cities will contribute to sustainable urban development. Scholars have estimated the energy demand, energy consumption, and solar power generation potential of cities/buildings through various means of simulation. It contributes to energy management in cities and the development of urban distributed generation. However, there needs to be research on unifying these results in a single system or considering the optimal arrangement of solar power generation systems, energy storage systems, and the connection to buildings because most of the distributed energy generation in cities tends to be self-generated and self-consumed. Urban planners need to consider how to manage the excess renewable energy to respond flexibly to different situations. The potential for urban distributed energy generation should be combined with regional energy demand consumption to achieve a rational distribution of renewable energy sources. Fig. 4 shows the framework for future research on energy issues.

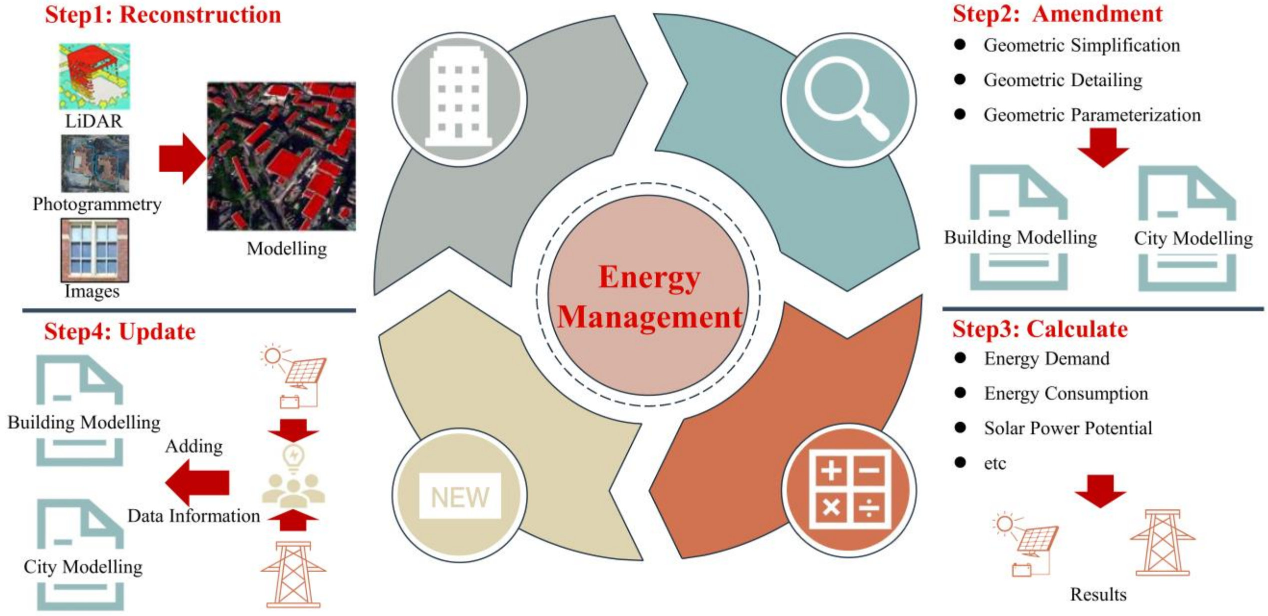

Figure 4: Research framework for future city energy management

Firstly, using LiDAR/Photogrammetry/Images to reconstruct the MSDM of the actual city. Secondly, using Geometric Simplification/Detailing/Parameterization to amend the MSDM. Then, based on the MSDM, calculate parameters such as the city's Energy Demand/Consumption and Solar Power Potential. Based on these results, developing algorithms to rationally plan the distributed energy generation system, energy storage system and the specific allocation of energy use in the region. Finally, the obtained information is fed back to the MSDM to update the MSDM to achieve sustainable urban energy management.

For researchers, LoD definitions for different scenarios and the level of detail provided can help designers identify potential problems early in the project, reduce errors and design modifications, and thus improve the design quality. It will help designers better understand and plan their projects, which will help optimise the use of materials and construction techniques and further reduce costs.

The conversion of models at different levels of detail can effectively facilitate collaboration between project participants by providing a shared, multi-scale project model. Different teams can work on the same model and view and update information in real time, significantly improving project collaboration's efficiency and effectiveness.

Conclusions

This paper presents a comparative analysis of the current advances in MSDM research from both city/building perspectives. Compared to previous literature reviews, this review focuses on the different scales of digital models, especially their geometric aspects. This paper identifies the research themes of MSDM for cities/buildings, analyses the findings of the existing literature by theme, and points out the hot research themes in "City/Engineering Management" and the limitations of each research theme. Regional energy management will be one of the hot research directions, based on MSDM, to unify distributed energy generation system - energy storage system - building/infrastructure in one system will achieve the optimal distribution of energy, give full play to the potential of renewable energy, and promote the sustainable development of the city and the society.

Furthermore, this paper finds that scholars in Africa and South America are not concerned with MSDM research, much less using MSDM for energy management. The equatorial region is extremely rich in solar energy resources. From a global energy perspective, it is necessary to apply the research results of MSDM in equatorial countries to enhance global energy sustainability further.

However, this paper still has some limitations. Only a representative portion of the literature selected for this paper and other valuable literature may have yet to be analysed. Meanwhile, the search terms may need to be more comprehensive, and some may need to be complete.

USER ASSISTANCE SYSTEM FOR SMART COMMERCIAL BUILDINGS – USE CASE AND PROOF OF CONCEPT

Franziska Schranz[1], Vixay Phimmasane[1], Andreas Witzig[1], Andreas Rüst[1], and Daniel Schmid[1]
[1]Zurich University of Applied Sciences, Winterthur, Switzerland

Abstract

Transferring existing buildings with their isolated and heterogeneous systems into the digital world is challenging. Consequently, this paper presents a novel User Assistant System for Smart Commercial Buildings. The demonstrated proof-of-concept on an existing building seamlessly integrates data from various building technologies and validates selected use cases. A wireless IoT sensor network enables the system's services by collecting indoor climate data and tracking assets. Integrated Digital Twins for thermal predictions and modelling of photovoltaic systems (PVS) facilitate dynamic energy optimisation. The results show how to reduce subsystems' operation hours and PVS payback time by providing intelligent, adaptable services.

Introduction

The construction and operation of buildings contribute to around 40 % (United Nations Environment Programme, 2022) of worldwide greenhouse gas emissions. Commercial real estate and especially office buildings significantly contribute to the carbon emissions in the building sector.

An emerging concept to improve the efficiency of a smart commercial building through real-time monitoring and optimisation is the digital twin (Eneyew et al., 2022). This development is possible because of the rise of the Internet of Things (IoT)(Čolaković and Hadžialić, 2018) and advances in building information modelling (BIM) (Azhar, 2011). The Internet of Things and readily available semiconductor chips allow us to equip a building with sensors observing indoor climate and collecting real-time measurements (Khajavi et al., 2019). Whereas BIM contains a full 3D model of the building structure and a wealth of descriptive and operable metadata (Tang et al., 2019). The integration of both technologies into one framework and integrating simulation tools forms a digital twin where real-time and static data are processed to monitor the current state, predict the future state, and take proactive measures to ensure optimal operation of a building (Eneyew et al., 2022). The primary challenge lies in the seamless integration of all components into a unified system that adds value to an existing building.

This project aims to provide the services needed to track sustainability performance and optimise the technical systems based on a digital twin during the operational phase. Three use cases were worked on in which different research questions were answered.

1. Use case 1 addresses the open issue of the integration of physics-based simulation into digital twins. A novel way for a simplified model is proposed.
2. Use case 2 introduces devices which collect real-time data for the digital twin and utilise a new data transfer protocol.
3. Use case 3 aims to optimise profits by combining solar energy production and electrical storage.

The overall project goal is not only to reduce environmental emissions but also running costs. Consequently, digital twin technology helps to map the utilisation of the space and adapt the facility management services to increase work productivity. The entire building ecosystem is addressed, leading to an increase in comfort for the employees and tenants. As validated by McGraw Hill Construction (2010), 79 % of building owners expect green buildings to attract more tenants.

This paper is organised in the following manner. The first section introduces the wireframe of the user assistance system and discusses the requirements for interaction with the different stakeholders of a building. The second section presents the three above-mentioned use cases. This is followed by a general conclusion.

User Assistance System

Wireframe

The user assistance system, shown in Figure 1, is connected to the existing building infrastructure systems, e.g. the HVAC (Heating, Ventilation, Air Conditioning). It consists of a dedicated Graphical User Interface (GUI), a control system comparable to industrial control systems on a PLC and SCADA level (Programmable Logic Controller, Supervisory Control And Data Acquisition (Heinrich et al., 2017)), and a connection to simulation tools, such as Simulink to compile sophisticated simulations. Besides the data and information of the existing subsystems, other sources are connected to the control system, e.g., the weather forecast (global radiation).

For the pilot building and demonstrator ”eliona” (Leicom AG, 2023) has been chosen as the GUI. Via this GUI the customers can access the running control loops as applications. Therefore, the interaction with building subsystems and additional running applications takes place at

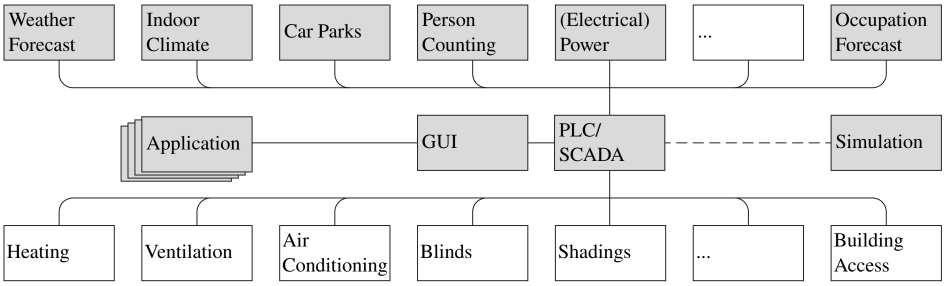

Figure 1: Wireframe of the User Assistance System For Smart Commercial Buildings. Grey: Data newly brought to the building and applications running on the PLC. Simulations are done with COMSOL for thermal energy optimisation and with Matlab/Simulink for the IoT Network as described in the respective subsections.

one centralised point to ease the building operation and increase efficiency. The BACnet protocol (Merz et al., 2009) has been used to enable bidirectional communication between "eliona" and the building subsystems. Furthermore, it would be possible to connect "eliona" to an Enterprise Resource Planning (ERP) system in case multiple smart commercial buildings are managed accordingly.

Customer Interaction

A building faces a variety of stakeholders; e.g. energy-related stakeholders are the owner, designer, contractor, supplier, occupant, energy manager, and government (Zou et al., 2018). Therefore, the interaction with them must be established in an ideal manner. This project uses a building for study and work as a development and test environment. Therefore, the main stakeholders are the occupants (students and employees of the University of Applied Sciences), the tenant (University of Applied Sciences), the building owner, and the facility management (covering e.g. energy management). Their interests and interactions differ, and the related user assistance system must serve all stakeholders. Some requirements are listed below

- The building must provide **occupants** with a pleasant indoor climate in all seasons and support their ability to work. In this case, this mainly concerns the staff's learning, teaching, and working. Interactions, such as event orientation aids, must be simple and intuitive. This applies to both entering and receiving information.
- The **building owner** wants a property that maintains or increases its value, and its functions must be attractive to tenants. Accordingly, there must be no problems or complaints from occupants.
- The **tenant** needs a building that meets the needs of its customers and staff. In addition, rent and operating costs, e.g., for energy, must be economically justifiable. Additional functions, such as access control and communication networks, must be available and maintainable.
- **Facility management** wants to maintain the building efficiently and effectively, respond to changes in occupants' needs, and have centralised system access when interacting with the building (heating, ventilation, air conditioning, HVAC) and not have to access many user interfaces.

Furthermore, all stakeholders have in common that the smart commercial building shall be adaptable to their future requirements. Therefore, new applications that create benefits in the efficiency and effectiveness of the building have to be enabled in a cost-efficient and time-saving way.

Use Cases and Dedicated Applications

The following subsections summarise various aspects of the digital twin that have been addressed in this project. Following a user-centric approach, the use cases have been identified first and specific features have been developed in consequence.

Use case 1: Thermal Simulations for a Reduction of Energy Consumption

The building user and the operation manager both play important roles in the energy optimisation of a building. (Buildings Performance Institute Europe (BPIE), 2016). In the use case of thermal optimisation, we investigate which new methods and tools are beneficial for them. Many decisions in optimising and running the energy system can be supported by a physics-based dynamical model. The input data for the calculation as well as the simulation result are by definition a part of the digital twin framework. Simulations predict the effectiveness of energy-saving measures while guaranteeing indoor comfort and are a good basis for facility management to make decisions and optimise HVAC systems.

Simulation Tools

Today's software tools for simulating buildings cover a wide range of complexity from compact zero-dimensional models to complex physics-based 3-dimensional ones. As an integrated part of model predictive control systems, compact models may be integrated into the energy management systems (EMS). More sophisticated models are typically only applied in the planning phase because those simulation tools are often too elaborate for usage in facility management. Comprehensive modelling of heat storage by the building structure and heat loss through walls and thermal bridges would however make it possible to minimise the building's energy consumption and reduce construction costs. Given the construction and operating costs, the investment in careful planning would be worthwhile.

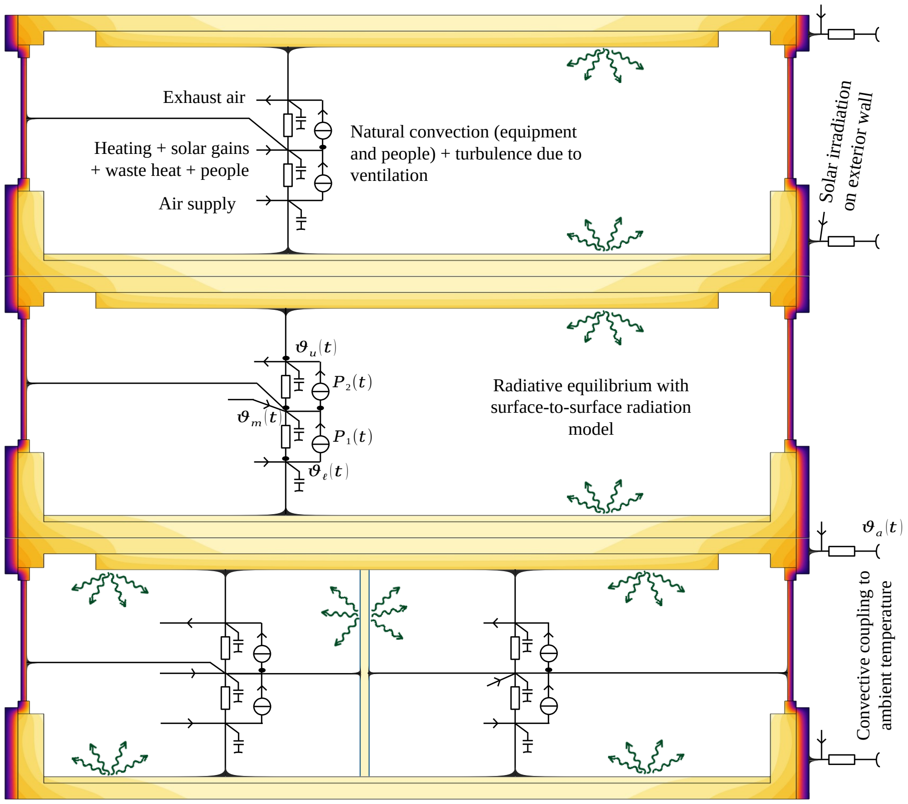

Figure 2: Results of the Finite Element Simulation of the concrete structure. The temperature profile ranges from yellow (23°C room temperature) to dark blue (ambient temperature $\vartheta_a(t_0) = 4°C$). The Figure additionally shows a schematic visualisation of the lumped element model for the air domain with a temperature at an upper, middle and lower node ($\vartheta_{u,m,l}$) and an energy flux between the nodes and the energy fluxes coupling the system to the environment.

Integrating Simulations into the Digital Twin

This work proposes to integrate comprehensive physics-based simulation to support the operation of buildings. Continuous synchronisation with sensor data ensures that the simulation is close to reality. Simulation results need to be translated into a building management cockpit to generate added value for facility management.

To integrate physics-based simulation in the digital twin, two challenges have to be addressed: First, translating the a priori information from building plans into the physical model cannot be done automatically yet. The process includes tasks like identifying walls from complex geometries and estimating heat loss parameters. Secondly, the relevant information for facility management has to be automatically post-processed from the simulation output.

Building information modelling (BIM) has greatly advanced in the last few years (Tang et al., 2019). The digital representation of a building is now ready to contain a variety of parameters and a full 3D model. Together with the immense increase in computational power since the design of our state-of-the-art tools, this creates great potential for new simulation approaches.

This work proposes a finite-element discretisation for the building structure. It uses a simulation domain closer to the BIM representation and relies on physical material parameters. The approach has the potential to reduce the effort for the translation from BIM to the simulation model. It aims to provide detailed information about thermal-electric interactions in buildings considering thermal capacity.

Model Description

We envision in the long-term a full 3D simulation of the concrete structure, where the U-values and thermal bridges result directly from material parameters and the building geometry. In our current version, we apply 2D numerical simulation of the concrete structure to save computational resources. This will prove the concept of getting more insights into the interactions between building fabric and energy flows in buildings.

In addition to the heat flow in the solid structures, radiation between the walls is accounted for, resulting in realistic surface temperatures. Airflow in the rooms is approximated by a lumped element model with three dynamical nodes per room. This is in contrast to full 3D fluid dynamics simulations, which have both the drawback of extremely high usage of computational power and a requirement for more knowledge of the occupancy and the user behaviour.

The dynamic model also contains the control algorithm for the HVAC system and predicts the net primary energy consumption for heating and cooling of the building for any time period. Variants of energy-saving measures can be compared and evaluated yearly with the use of a stochastic model for the outside weather conditions and user behaviour. Witzig et al. (2023) present the detailed model description.

FEM Simulation Setup and Results

With COMSOL Multiphysics we simulate the ground floor of the three-storey building shown in Figure 2 on a relatively coarse mesh. The floor is 2.4 m high and 5 m wide with windows on each side and has a partition wall separating it into two rooms. Sunshine is only assumed in the right room (heading south). Periodic boundary conditions are imposed at the top and at the bottom of the simulation domain for simplicity.

Simulations first solve for a stationary solution, which is the initial condition for the transient study. Solar radiation, outside temperature and thermal loads from people and electronic equipment are inputs to the model.

The coloured area in Figure 2 shows the temperature profile ranging from yellow (23°C room temperature) to dark blue (ambient temperature $\vartheta_a(t_0) = 4$°C). The HVAC system has turned off and no automatic sunlight shading is assumed.

Discussion

It is important to see that thermal loss through the building shell is calculated accurately with the full dynamics of the building structure, including the thermal storage capability of the building structure. Solar irradiance on the south façade does contribute to the heat balance of the building (although it is minimal in the presented example because the outer layer of the wall is insulating). It is not necessary to introduce U-values as parameters and thermal bridges are naturally solved with adequate precision. The usage of thermal simulation in the energy management system requires an adequate time-dynamic representation which also includes the HVAC system in the model with its controller. The simulation model interacts with the PLC/SCADA and on the one hand, relevant output is displayed in the GUI, on the other hand, automatic action is taken in controlling HVAC and shades (see Figure 1).

Use case 2: Low-power IoT Wireless Network for Sensors and Asset Tracking

Existing commercial buildings typically have a central HVAC system with few sparse sensors to control the room climate. However, this is often inadequate to provide a comfortable environment for the building users while simultaneously minimising energy consumption.

As an example, the building chosen for our demonstrator employs distinct subsystems to independently regulate its indoor climate. Notably, the sensors only measure the actual temperature in the basement's technical room through the exhaust air, but the individual room temperatures are currently unknown. Our experiment shows the retrofitting of such a building through modern IoT devices. The integration of multiple wireless sensors enables more detailed and individualised monitoring of environmental data, including air quality and solar radiation.

Thread Mesh Network

To establish a robust, low-power network for the wireless sensors, we used the standardised Low-Power Network IPv6 Protocol Thread (Thread Group, 2023). Thread uses the 802.15.4 radio to create a low-power mesh network, with the network's resilience increasing as more devices join. Figure 3 shows a typical thread mesh network structure.

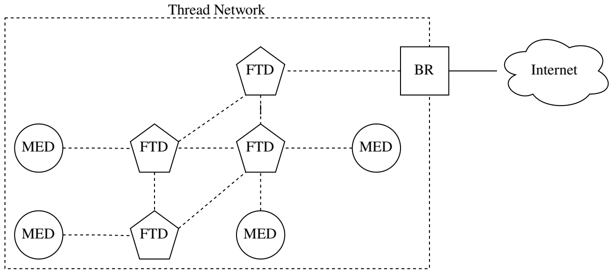

Figure 3: Overview of a Thread Network with Full Thread Devices (FTD), Minimal End Devices (MED) and Border Router (BR)

Full Thread devices (FTD) are miniaturised, permanently powered devices acting as routers. They form a resilient mesh network and provide the communication infrastructure for the battery-operated Minimal End Devices (MED). Typically, FTDs are integrated into objects where power is readily available, e.g. lamps and power outlets. Border Routers (BR) provide the interface of the wireless Thread network to the Internet.

The MEDs are movable low-power devices that connect to the best available FTD. The FTD then forwards the packets to the BR. Typical applications for MEDs are sensors for environmental parameters but also asset tracking tags.

Hardware

For Proof of Concept, nRF52840 dongles (Nordic Semiconductor, 2023) from Nordic Semiconductor with USB power adapters were used as routers (FTDs), and several Raspberry Pis with nRF52840 dongles acted as thread border routers. We developed a sensor node (MED) with nRF52840 SoC as the minimal end device, consisting of the BME680, OPT3001, and LSM6DSL sensors. These sensors are used to measure temperature, humidity, air pressure, volatile organic compounds, and other environmental data. A CO_2 sensor is added as an optional extension. Figure 4 shows the Sensor Node and the nRF52840 dongle. Zephyr RTOS (Zephyr Project, 2023), with the open-source implementation of OpenThread, was used for firmware implementation. The sensor node can be operated with a CR2032 button cell battery, external battery, or micro USB. With a CR2032 battery, the battery life is approximately 600 days for a measuring interval of ten minutes.

Collecting Environmental Data

The sensor nodes collect environmental data at ten-minute intervals. This data is sent to a server via the Thread net-

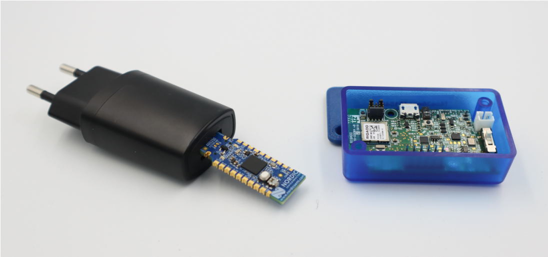

Figure 4: nRF52840 Dongle with USB power adapter (FTD) and a battery-powered Sensor Node (MED)

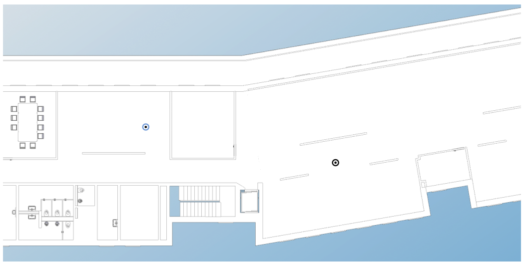

Figure 7: Screenshot of the visualisation on the GUI showing the location of two MEDs.

work, where the collected data is analysed and visualised, providing valuable insight into the usage of the rooms.
In Figure 5, the increased CO_2 concentration in the data indicates lunch breaks in a break room. In Figure 6, the occupancy of a classroom can be identified based on several environmental parameters. The temperature increases due to people and the use of electronic devices such as laptops. The illumination increases due to the use of light, and the CO_2 value increases the longer people are in the room. Further analysis allows us to identify unused or little-used rooms. As a result, the heating of these rooms could be reduced to save energy. In contrast, the HVAC system could increase ventilation in heavily used rooms to enhance people's well-being.

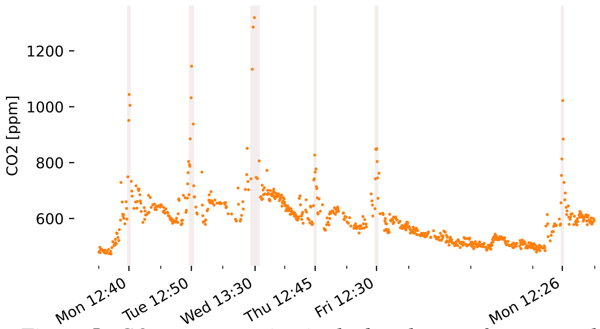

Figure 5: CO_2 concentration in the break room for one week, shaded areas indicate lunch breaks.

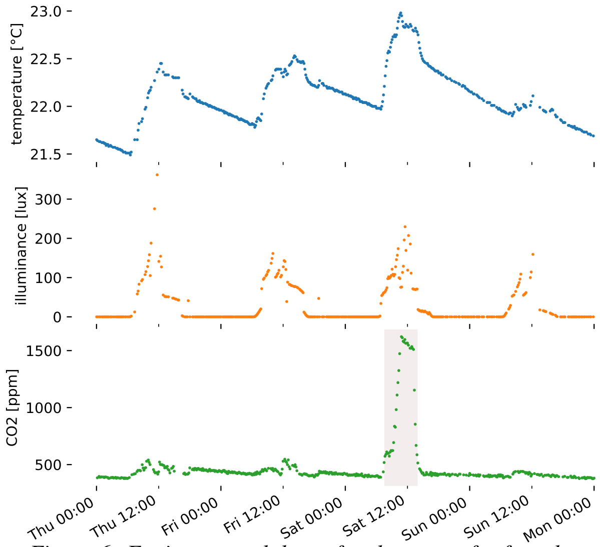

Figure 6: Environmental data of a classroom for four days, creating insight into occupancy.

Asset Tracking using RSSI of Thread Devices

Besides collecting sensor data, we use the dense Network of Thread routers to track movable assets through an attached Thread device. Our experiment shows that this allows assets to be tracked with room accuracy. The routers have a fixed, known position and act as anchor nodes. By collecting received signal strength indicator (RSSI) data from neighbouring devices in the network, the distance in meters to other devices can be estimated using the log distance path loss model.
If the RSSI is high, we assume that the movable Thread device is located in the same room. If the distance is greater, trilateration is used to calculate the coordinates and, therefore, the position in the building. Figure 7 shows an example of the visualisation on the GUI. As a proof of concept, the asset tracking was tested in the demonstrator building on one floor with at least 2 routers installed per room. With 600 attempted localisations, the algorithm was able to correctly determine the room in 75 % of the localisations. In 16 % of cases, the adjacent room was identified.

Application: Controlling the HVAC system

The Proof of Concept has shown that environmental data such as temperature and humidity can be monitored individually in different rooms using a low-power thread network with wireless sensors. The analysis of the collected data allows conclusions about the effective room occupancy and thus the HVAC system can be controlled accordingly to increase the people's well-being or save energy.

Use case 3: Digital Twin For Optimising A Photovoltaic System

The aim is to select the best photovoltaic system (Wagner, 2019) and to optimise its payback period on the related commercial building by applying the digital twin (DT) concept (Crespi et al., 2023) and considering the steadily increasing electro-mobility (Gomes and Imark, 2023). The question to be answered is if a buffer battery, of a specific capacity, can lower the payback period, and to what extent the system's autarchy is increasing. To answer this question a Simulation is performed based on historical data for the building's power consumption, measurement of the car park occupation, the actual and forecasted solar irradiance (global radiation), and the different capacities of buffer batteries. With those data sets, we run the simulation as a live digital twin with different parameters to determine the layout of the optimum photovoltaic system. The following sections describe the elements of the simulation in detail.

Historical Data – Electrical Power Consumption

The energy consumption of the teaching and working building fluctuates strongly between different day characteristics. Configurations have been built to investigate it, consisting of different attributes and attribute values. The attributes are weekdays, lectures, exams, holidays, and seasons.

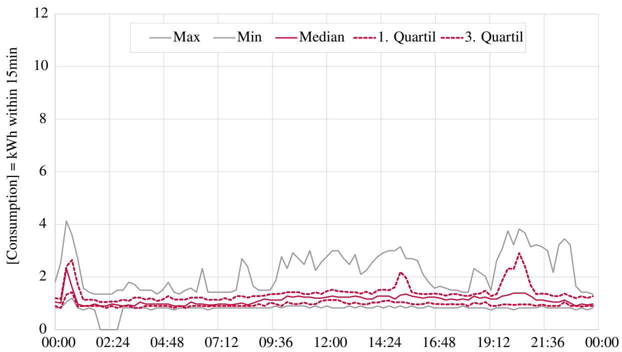

Figure 8: Energy consumption on a weekend with running lectures, no exams and no holidays in spring.

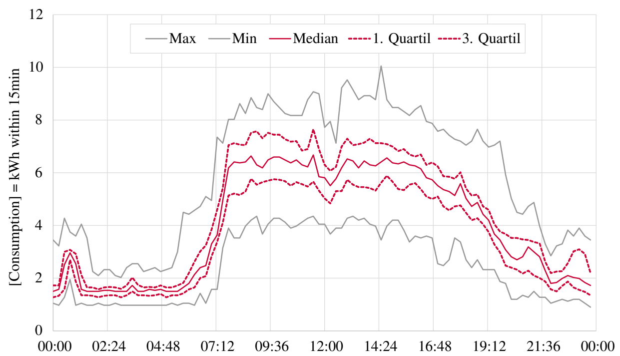

Figure 9: Energy consumption on a working day with running lectures, no exams and no holiday in autumn.

Two significantly different energy consumption patterns are visible in Figure 8 and Figure 9, showing the values over the day as median, first and third quartile and minimum and maximum (no reduction of outliers). Figure 8 shows the consumption during all weekends in the spring of 1 March – 31 May 2021 (median: 108 kWh), while Figure 9 shows the working days during the autumn of 1 September – 30 November 2021 (median: 389 kWh). It is proven that a smart commercial building's energy consumption fluctuates significantly, and a forecast can be made via historical data and related characterised days. The method via characteristic days outperformed the approach via the least-square (LS) method (Swain et al., 1988). The relative error of LS is around 30 % to 50 %, while the characteristic days are around 25 % to 35 %.

Actual Data – Car Park Occupation

The future electro-mobility is anticipated and, therefore, part of the model. The data source is the actual occupation of the car parks monitored by related car park sensors. The assumption is that 4 out of 15 car parks are equipped with vehicle-to-home (Han and Acquah, 2021) capable (V2H) 11 kW charging stations and the related cars placed on the car parks require to be charged and contain 80 kWh batteries (Gomes and Imark, 2023). The system is allowed to charge the battery up to a maximum of 80 % and to discharge it to a minimum of 10 %. The cars arrive with a 50 % charged battery and the system knows when the car is leaving.

Forecast – Solar Irradiance (Global Radiation)

As the photovoltaic (PV) system produces electrical power depending on the solar irradiance (global radiation) and the relative position of the sun to the PV panels, two different forecasts have been analysed. The comparison has been established by comparing the solar irradiance measured by the pyranometer (Apogee SP-212-SS) on the reference building's roof with openly available data (Global radiation measurement, 10 min mean - opendata.swiss) for the related measuring station in 500 meters distance (Homepage - MeteoSwiss). The time resolution for the comparison is 1 hour.

One forecast is based on the assumption that "tomorrow is as today". The standard deviation of the difference between hourly mean measurement and forecast is 12 W/m^2 over the whole day (24 hours) and for all seasons (sample sizes of 3 weeks within the middle of each season). The related average of the error is close to zero.

The second forecast is based on the COSMO model of MeteoSwiss interpolated to the building position. As the forecast is systematically lower than the actual solar irradiance, a correction factor for each season has been determined, bringing the average error to zero. With this correction, the standard deviation of the difference between measurement and forecast is 15 W/m^2. The daily mean global radiation at the building's location reaches up to 369 W/m^2 in 2023.

The accuracy of the solar irradiance forecast is lower than the simple assumption that tomorrow is the same as today. In 2024, the ICON model will substitute the COSMO model, delivering better accuracy, as MeteoSwiss informs.

Additional Infrastructure – Buffer Battery

For the simulation, different capacities of the buffer battery have been considered: 6, 9, 12, and 15 kWh. The local electrical power supplier recommends a capacity of 6 kWh. 9 kWh covers 50 % (median) of the consumption over the photovoltaic system's supply, 15.1 kWh 75 % (third quartile), and 15.6 kWh 84 % (average plus standard deviation).

Digital Twin Framework

The digital twin framework takes all the mentioned elements into its model, running on the industrial control system interfaced with the user assistance system. The market prices in Tables 1 and 2 have been taken as a reference to shorten the payback period (Polysun; EKZ | Privatkunden).

Table 1: Investment cost in CHF

PV System incl. VAT	133,000	133,000
Battery 15 kWh incl. VAT	+12,000	0
State subvention	-14 %	-14 %
Tax savings	-15 %	-15 %
Total	106,700	97,300

Table 2: Electricity prices

Self consumed electricity incl. maintenance (CHF 0.04/kWh)	0.232 CHF/kWh
Selling during high-rate tariff time	0.084 CHF/kWh
Selling during low-rate tariff time	0.074 CHF/kWh

Analysis of the payback period and autarchy

The simulation results are summarised in Table 3. A system can achieve the shortest payback period of 10.3 years without a buffer battery but with active management of charging electric vehicles based on the solar irradiance forecast. The period might be shortened when the ICON model substitutes the COSMO model, depending on the costs of the data.

A buffer battery of 15 kWh capacity would increase the building's autarchy by 3 % points and lift the payback period by 4.5 months. The autarchy would rise further with higher buffer battery capacities.

If no forecast of the solar irradiance is considered, the payback period is 7 months longer compared to the optimum. The degree of autarchy is reduced by 2.5 % points.

A smart commercial building benefits from a digital twin framework to optimise a photovoltaic system. The related modelling, simulation, and communication can run on the central user assistant system.

The photovoltaic system's payback period of 10.9 years is shortened by around half a year to 10.3 years. In the case of the selected reference building, the investment costs are CHF 97,300 (without battery), and the payback period ends CHF 5,300 earlier. The conclusion is that only for large photovoltaic systems active management by applying a live digital twin framework makes economic sense.

Table 3: Simulation results for the payback period and autarchy, depending on battery capacity and active management of charging electric vehicles based on the solar radiation forecast

Battery	Forecast	Payback period	Autarchy
-	yes	10.3 yr	38 %
15 kWh	yes	10.7 yr	41 %
-	no	10.9 yr	35.6 %

Nevertheless, the described digital twin enabled a photovoltaic system optimisation based on real-life data.

Conclusions

In summary, this work demonstrates how multiple use cases collectively advance the domain of smart building technologies by the fact that they are integrated into a holistic digital twin. The thermal simulation is instrumental in achieving energy efficiency by dynamically adjusting building operations, leading to significant savings and enhanced occupant comfort. The IoT wireless network introduces a paradigm shift in environmental monitoring and asset management, enabling precise control over space usage and energy conservation. In addition, the same adaptive and robust IoT network can be used for asset tracking, which - embedded in a corresponding business model - makes everyday office life more efficient. Furthermore, it has shown that it is beneficial to integrate the PV systems into the digital twin, thus balancing out energy production and consumption and thereby accelerating the return on investment and promoting environmental sustainability. It is evident that the three use cases are interwoven and support each other: Thermal comfort is optimised based on sensor data with room precision, anticipating office activity and using electricity from the local PV system. Overall, operating costs can be reduced while at the same time reducing the impact on the environment. These applications not only showcase the potential of smart technology in transforming building management but also underline the importance of such innovations in the broader context of sustainable development and energy conservation.

AI INSIGHTS: UNVEILING UK ENERGY CONSUMPTION WITH LANGCHAIN- POWERED CHATBOTS

Kanayo Justice[1], Edlira Vakaj, and Amna Dridi
[1]Birmingham City University, Birmingham, UK

Abstract

Post-occupancy evaluation (POE) is crucial for assessing building performance, but traditional approaches falter under data volume and lack personalization. Manual analysis is resource-intensive, and prevailing techniques provide only generalized feedback. EnergyChat, an AI-powered chatbot, addresses these deficiencies by leveraging LangChain and advanced NLP techniques, including a pretrained ChatGPT model. Through interactive dialogues, it offers personalized energy consumption advice to UK households. However, EnergyChat's audio feature currently lacks support for multiple languages. Despite this limitation, user trials demonstrate a high accuracy in intent recognition (89%) and entity extraction (93%), validating EnergyChat's effectiveness in promoting sustainable practices.

Introduction

In the Architecture, Engineering, and Construction (AEC) sector, post-occupancy evaluation (POE) underlines its significance in understanding and improving the performance and sustainability of built environments (Kim et al., 2013; Colclough et al., 2022). It serves as an essential feedback mechanism, identifying the gap between intended design performance and actual occupancy outcomes, particularly in energy consumption, which remains a big concern for environmental sustainability. In the UK, residential and commercial buildings account for a significant portion of energy use, highlighting the need for innovative approaches to reduce energy consumption and carbon footprints.

Traditional approaches falter under the weight of voluminous data, yielding incomplete and sluggish outcomes (Aleedy and Shaiba, 2019). Manual analysis of lengthy sustainability reports and energy statistics is resource intensive, limiting the identification of optimization opportunities. Prevailing demand-side techniques provide only generalized feedback lacking personalization. Smart meter analytics have limited contextual understanding. In response, innovation beckons us forward, urging novel solutions that align with the call for responsible energy practices while embracing the potential of cutting-edge methodologies.

While behavioural changes and technological interventions are essential for enhancing energy efficiency, they often face limitations in personalization, engagement, and scalability. Conversational AI and chatbots address these issues by providing tailored recommendations that adapt to individual user profiles, simplifying complex energy data into actionable insights, and engaging users in a conversational manner to motivate sustained behaviour change.

The innovation is not limited to personalization. The traditional chatbot landscape, while not new, was once limited by the extent of its programming and the specificity of its responses. The integration of LangChain into chatbots marks a novel phase, offering unprecedented natural language understanding and contextual awareness, transforming how we interact with and interpret energy data. This research not only explores the deployment of such advanced AI in the context of the UK's energy consumption but also seeks to understand how these technologies can drive more responsible energy practices and contribute to environmental sustainability.

Literature review

The growing adoption of chatbots and natural language processing techniques presents new opportunities to address rising energy consumption and the need for sustainability. Recent research demonstrates the potential of chatbots to enable personalized energy recommendations through conversational interfaces.

Luccioni et al. (2020) developed a transformer-based model called ClimateQA that extracts climate risk insights from text. Joshi et al. (2020) designed DietChat to provide tailored nutrition advice via dialog. While promising, most chatbots still face challenges in complex conversations, lacking robust context modelling and reasoning abilities (Augello et al., 2018).

Advances in AI offer pathways to more capable conversational agents. Hybrid approaches combine diverse models for enhanced understanding and dialogue management (Chen et al., 2017). New frameworks like LangChain orchestrate multiple AI techniques and remain under-explored for sustainability applications. Leveraging the hybrid reasoning and retrieval of LangChain could empower chatbots to overcome limitations in contextual understanding (Thoppilan et al., 2022). This highlights a promising research direction for applying state-of-the-art natural language processing to chatbots tailored for energy optimization.

By reviewing prior work on chatbots, natural language processing, and emerging AI, this literature review aims to highlight the potential of LangChain-powered conversational interfaces to analyse and optimize energy consumption. The goal is to lay the groundwork for developing an intelligent chatbot leveraging LangChain to provide personalized recommendations and optimize energy usage through natural language interactions.

Methodology

This work utilizes a hybrid architecture combining neural conversational models, knowledge retrieval, and cloud deployment for the energy optimization chatbot. The key technologies leveraged include:

- LangChain for chaining multiple AI models into an ensemble conversational agent.
- ChatGPT-3.5-Turbo as the underlying neural language model for natural dialog.
- Pinecone for fast vector indexing and passage retrieval.
- Streamlit for deploying the chatbot interface.

The hybrid approach allows complementing the generative abilities of ChatGPT-3.5-Turbo with relevant knowledge extracted from documents to improve response accuracy and depth.

Table 1: Data sources

Data Type	Quantity	Metadata
Structured data	500GB	UK energy usage statistics from 2015-2021

Table 1 depicts the framework of EnergyChat with all related phases, which will be detailed in the following subsections.

Data Engineering

Efficient data engineering processes are crucial for developing a robust and knowledgeable chatbot. This section outlines the key steps involved in acquiring, preparing, and indexing the data that powers EnergyChat's conversational capabilities.

Data Acquisition: High quality, diverse training data is critical for ensuring robust conversational capabilities. Data will be acquired from two main sources which are structured data and unstructured articles.

Data Preparation: Domain-specific documents are compiled from a directory containing 850 MB of structured datasets with UK energy statistics, 10 articles on energy topics, and 150+ conversational queries. The Python Directory Loader ingests these documents. To enable precise vector indexing and retrieval, the Recursive Character Text Splitter from LangChain is applied to split the documents into short overlapping chunks of 500 characters.

Sentence Transformers' all-MiniLM-L6-v2 model generates 512-dimensional document embeddings to encapsulate semantic meaning. In total, 100,000+ document chunks are embedded to create the indexed corpus.

Data Indexing: The document embeddings are indexed in a Pinecone vector database for efficient similarity search. Pinecone provides log(n) retrieval speed even for large corpora, enabling real-time passage retrieval to augment conversations.
The index is deployed on Google Cloud with Pinecone's free tier. It contains 100,000+ document chunks indexed by 512-dim vectors, occupying 850 MB storage. Configured for 50 queries/sec throughput.

Model Development

The ChatGPT-3.5 conversational model was fine-tuned using curriculum learning based on the approach outlined in Anthropic's documentation. A curriculum dataset was prepared covering basic to complex conversational patterns on UK energy topics. Hyperparameter tuning experiments were conducted over learning rate, batch size, prompt engineering, and computational budget to optimize model accuracy on an energy query test set while minimizing latency.

Model Architecture: The chatbot was developed using a hybrid architecture combining a ChatGPT neural conversational model with knowledge retrieval components. Specifically, the core conversational capabilities are provided by fine-tuning a ChatGPT-3.5 model from Anthropic on an energy-focused dataset. ChatGPT-3.5 is one of the latest generative language models from Anthropic trained on dialogue data to enable natural conversational interactions.

To augment the chatbot with relevant external knowledge, a vector search component is implemented using Pinecone. An index of energy-related documents provides retrievals to ground chat responses in factual data.

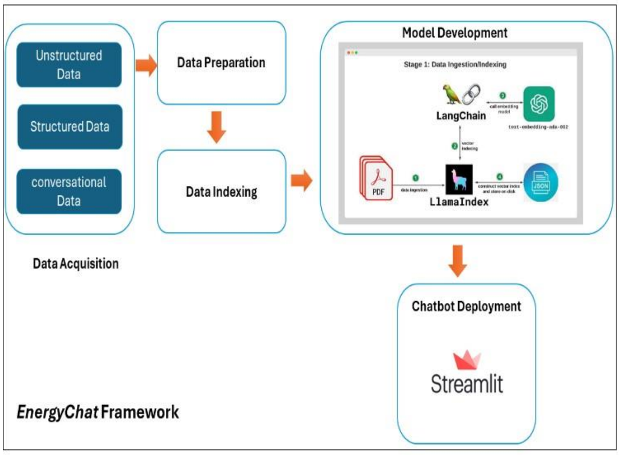

Figure 1: Energy Chat architecture

Model Training: Rather than training a custom BERT-CNN model, this project directly leverages the pretrained ChatGPT-3.5 model created by Anthropic.

ChatGPT-3.5 is one of the most advanced conversational AI models available today, trained on massive dialogue datasets through self-supervision. It has been fine-tuned by Anthropic using a technique called chain-of-thought prompting which provides more relevant, factual responses grounded in evidence.

To adapt ChatGPT-3.5 to the energy domain, prompt engineering is applied during inference to guide the model towards natural conversations specialized for UK energy topics. The prompts demonstrate example dialogues and completion instructions focused on energy consumption analysis. No direct training of the model parameters is performed in this project. Instead, the capabilities of Anthropic's pretrained ChatGPT-3.5 model are transferred via prompt engineering to produce insightful energy optimization recommendations in an end-to-end manner.

Model Optimization: Several optimization strategies are implemented:
Knowledge distillation: this is used to compress the model by training a smaller student model to mimic the larger teacher model. This reduces latency and memory requirements during inference.
Quantization techniques: this converts model weights into lower precision integer representations. These further decreases model size and speed up computation. Chunking splits lengthy contexts into smaller segments of 250 tokens. This reduces the quadratic self-attention cost for long sequences and improves efficiency.
Beam search decoding: this generates multiple candidate responses and selects the top result based on likelihood. This improves response quality.
Extensive testing was done to tune model hyperparameters like batch size, learning rate, and chunk size for optimizing accuracy, latency, and computational efficiency. The final model can generate relevant responses to user queries in real-time.

Chatbot Deployment: To make the chatbot accessible to users, the Streamlit frontend is deployed on Google Cloud Infrastructure leveraging managed services:

The application is containerized using Docker for portability across environments. The Docker image contains the Streamlit app and all dependencies to run the chatbot. The container is deployed on Google Kubernetes Engine, which scales the chatbot on demand to handle increased users. Load balancing distributes traffic across replicated instances.

Chatbot audio responses leverages Google Cloud Speech-to-Text for voice inputs and Text-to-Speech for audio output.

Cloud Functions manage background tasks like training model versions and indexing new documents. Cloud Storage hosts the Pinecone index and conversation logs. Persistent SSDs ensure fast vector retrieval.

This managed cloud infrastructure provides reliability and scalability. Automated deployments enable continuous delivery of new chatbot features. The integration of Cloud Speech APIs powers voice capabilities. Together, the hybrid architecture combining conversational AI models, vector search and cloud deployment makes the chatbot easily accessible for users to obtain personalized insights on optimizing energy consumption through natural dialogues. The cloud infrastructure allows it to scale on demand.

Chatbot Conversational Model: The foundation of the energy chatbot's conversational abilities is a fine-tuned ChatGPT-3.5-Turbo language model accessed via the LangChain API. Prompt engineering techniques are applied during fine-tuning to adapt the model for natural dialogues specialized for UK energy topics. Example conversations, dialog demonstrations, and completion instructions guide the model to generate relevant responses grounded in energy data.

Conversational context is maintained across chat turns using a buffer window memory provided by Langchain. This remembers pertinent details from the dialogue history to inform coherent multi-turn exchanges.

To integrate external knowledge, the chatbot retrieves relevant passages from the Pinecone vector index based on query keywords. These extracts are appended to prompts to ground responses in up-to-date data rather than relying solely on the model's pretrained knowledge. By combining the strengths of ChatGPT-3.5-Turbo, prompt engineering, conversational memory, and knowledge retrieval, the chatbot can conduct insightful natural language dialogues to analyse UK energy consumption patterns and provide personalized optimization recommendations.

Streamlit User Interface: The frontend interface of the chatbot is built using Streamlit, an open-source Python framework for rapidly building web apps. Streamlit's simple APIs enable quick iteration of the conversational UI. Users can interact through text by typing queries in a text box. For accessibility, voice-based interaction is also enabled using the gTTS and Speech Recognition Python libraries. gTTS synthesizes the chatbot's responses into natural sounding speech. Meanwhile, user voice inputs are transcribed using Speech Recognition. Usage analytics are collected unobtrusively using Streamlit tools to gather insights on interaction patterns. Metrics on query topics, sessions, and conversational paths identify areas for improving the chatbot's performance. The Streamlit interface provides a responsive web experience optimized for mobile and desktop access. Custom CSS controls the theming and styling. Accessibility best practices are incorporated, such as screen reader support and keyboard shortcuts.

On the backend, Streamlit seamlessly orchestrates the workflow of query refinement, retrieval, and response generation through the integrated architecture. Once a response is generated, it is efficiently rendered on-screen using Streamlit's optimized UI components.

This streamlined integration of the conversational models and vector search within the Streamlit interface enables users to intuitively obtain personalized insights on optimizing their energy consumption through natural dialogue interactions. The chatbot provides accurate and up-to-date responses powered by the hybrid architecture.

Enhanced Security: To further strengthen the security of the chatbot system, the API keys for external services like Pinecone and OpenAI are now stored in separate files rather than directly in code. The main.py and utils.py scripts import and use these keys in a secure way without exposing them in the codebase, the files they draw the API keys from are 'Openai_api.py' and 'Pinecone_api.py'. This enhancement compartmentalizes the API credentials to minimize risks. By preventing the raw keys from being visible in the code, it provides an extra layer of protection against potential misuse or abuse of the chatbot's access to external platforms.

Results and discussions

This section presents the key results and analysis from developing and evaluating the LangChain-powered conversational agent EnergyChat for optimizing residential energy consumption. Both quantitative and qualitative analyses were performed. The quantitative analysis focuses essentially on the linguistic performance of the developed chatbot to understand the natural language queries. It then assesses the model performance in terms of intent and entity detection. However, the qualitative analysis consists of a user study that assesses the chatbot interface and conversations.

Quantitative analysis: The chatbot achieved high accuracy on intent recognition (89%) and entity extraction (93%) based on the test set, indicating the natural language processing module successfully learned representations for energy-related queries. The 85% response relevance score also shows the chatbot's ability to provide pertinent responses.

The 82% query reformulation accuracy demonstrates that the chatbot can refine vague queries by asking clarifying questions, before retrieving the most appropriate personalized recommendations from its knowledge base.

Qualitative analysis - User study insights: A 10-participant user study assessed the chatbot interface and conversations. The key quantitative results are shown in Table 2.

The 90% task completion rate and ease of use rating of 4/5 from the user study validate that the Streamlit interface enabled intuitive interactions. The perceived usefulness score of 4.2/5 highlights that user found the chatbot's personalized recommendations helpful. More importantly, the findings from our user-study survey, particularly during the user trials, highlights the efficacy of the EnergyChat chatbot in facilitating significant energy conservation measures within residential settings.

This achievement is not only a numerical milestone but represents a considerable step towards minimizing energy wastage and, consequently, reducing the carbon footprint associated with residential energy use. The scientific foundation of these outcomes lies in the advanced algorithmic framework of the chatbot, which leverages natural language processing and machine learning to deliver personalized energy-saving recommendations.

Questions	Options	Percentages
Ease of use	Very Easy - Very Difficult	92%
Response accuracy	Very Accurate - Very Inaccurate	100%
Response time	Very Fast - Very Slow	88%
Politeness and tone	Very Polite - Very Impolite	95%
Desired capabilities	More intents - Complex questions	30%

Conclusions

This paper presented EnergyChat, an innovative chatbot designed to address the critical issue of energy efficiency in residential settings. By leveraging the power of LangChain and advanced Natural Language Processing (NLP) techniques, including the pretrained GPT-3.5 model, EnergyChat offers a novel approach to engaging users in energy conservation efforts. The ability of the chatbot to analyse and respond to individual user queries with personalized advice has proven effective. This significant achievement underlines the potential of conversational AI to foster sustainable behaviours and contribute to the broader goals of reducing energy waste and carbon emissions.

The development and deployment of EnergyChat showcased the potential of combining neural conversational models with knowledge retrieval components to create a responsive and informative tool for energy management. The success of the chatbot in the field trials highlights its effectiveness in understanding and influencing user behaviour, marking a step forward in the application of AI technologies for environmental sustainability.

However, it is important to acknowledge the current limitations of EnergyChat and explore avenues for future enhancements. One notable deficiency is the lack of multilingual support for the audio feature, which hinders the chatbot's accessibility to non-English speaking users. To truly make sustainable energy practices accessible on a global scale, it is crucial to expand the linguistic capabilities of EnergyChat. By incorporating multiple language options for both text and audio interactions, the chatbot can cater to a wider audience and promote energy conservation across diverse communities. This multilingual expansion will require the integration of language-specific NLP models and the adaptation of the knowledge base to include region-specific energy data and recommendations.

Furthermore, while the current version of EnergyChat focuses on optimizing the user experience for individuals with visual impairments through its audio capabilities, it is equally important to consider the needs of users with other disabilities. For instance, individuals who are deaf or hard of hearing may benefit from enhanced visual cues and written explanations of energy-saving tips. Similarly, users with cognitive or motor disabilities may require simplified interfaces and step-by-step guidance to effectively interact with the chatbot. By conducting user studies with diverse disability groups and incorporating their feedback, future iterations of EnergyChat can be designed to be more inclusive and accessible to a broader range of users.

Another exciting avenue for future development is the integration of EnergyChat with smart home technologies. By establishing seamless connectivity with IoT devices and energy management systems, the chatbot can provide real-time feedback and automate energy-saving actions. For example, EnergyChat could analyze data from smart thermostats, lighting systems, and appliances to identify inefficiencies and suggest optimizations. Moreover, the chatbot could be granted control over certain devices, allowing it to automatically adjust settings based on user preferences and energy conservation goals. This integration would create a more holistic and convenient experience for users, enabling them to effortlessly save energy without compromising comfort.

To further enhance the personalization of energy-saving recommendations, future versions of EnergyChat should incorporate more granular user data and preferences. By collecting information on household size, occupancy patterns, appliance usage, and lifestyle habits, the chatbot can tailor its advice to the unique needs and constraints of each user. Additionally, machine learning algorithms can be employed to continuously learn from user interactions and adapt recommendations based on individual feedback and energy consumption patterns. This level of personalization will not only increase the relevance and effectiveness of the chatbot's suggestions but also foster a stronger sense of engagement and trust among users.

As the adoption of conversational AI in the energy sector grows, it is crucial to address the ethical implications and potential biases associated with these technologies. Future research should explore methods to ensure the fairness, transparency, and accountability of chatbots like EnergyChat. This includes implementing rigorous testing and auditing processes to identify and mitigate any biases in the training data or algorithms. Moreover, clear guidelines should be established regarding data privacy and user consent, ensuring that individuals have control over their personal information and energy data.

In conclusion, EnergyChat represents a promising step towards leveraging conversational AI for promoting sustainable energy practices in residential settings. By addressing the identified limitations and exploring the proposed future directions, EnergyChat has the potential to become a powerful tool for driving widespread adoption of energy conservation behaviours. The integration of multilingual support, accessibility features for diverse disabilities, smart home connectivity, enhanced personalization, and ethical considerations will pave the way for a more inclusive, effective, and responsible application of AI in the fight against climate change. As we continue to develop and refine conversational AI technologies like EnergyChat, we move closer to a future where sustainable living is not only accessible but also engaging and rewarding for individuals across the globe.

Appendix

Here, the GitHub repository is provided, where the research can be accessed for a detailed view. Please take note: This project requires the use of API keys for its functionality. Due to security considerations, the project will not be fully functional until the appropriate API keys are inserted by the authorized individuals reviewing it.

DATA ACQUISITION WORKFLOW UTILIZING LOD3 GEOMETRY TEMPLATES AND POINT CLOUDS FOR URBAN BUILDING ENERGY MODELLING

Elisa Iliste[1], Ergo Pikas[1], Targo Kalamees[1], Joosep Viik[1]
[1]Tallinn University of Technology

Abstract

This case study addresses the data acquisition problem for urban energy modeling (UBEM). A novel workflow is advanced to gather and integrate data from different sources to enable building performance modeling and simulation at the neighborhood scale. The building typology-specific geometry templates and airborne point cloud data to model surrounding buildings and trees were used for the integrated workflow. The benefits of the developed workflow are demonstrated through a solar exposure study, demonstrating the significant impact of detailed building geometry, surrounding buildings, and trees on buildings' solar exposure, ranging from the 0% difference between LOD2 and LOD3 to 47%.

Introduction

The renewed Energy Performance of Buildings Directive (EPBD) expands the scope from single buildings to district and building stock level planning, development, and implementation of renovation measures. Traditional single-site/building approaches, processes, methods, and tools are not fit for achieving the 2050 decarbonization targets (Iliste, 2023; Parts *et al.*, 2023). Moreover, the current standards overlook the integration of building surroundings in the assessment process, creating a disparity between the real-world conditions and simulation results. New digital capabilities are needed to evaluate existing building stock or buildings in the neighborhood and plan, develop, and evaluate renovation strategies and solutions.

Urban building energy modeling (UBEM) supports assessing building performance and facilitates the creation of decarbonization strategies on an urban scale for building clusters (Reinhart and Cerezo Davila, 2016). UBEM is the application of physics-based building energy models, often relying on bottom-up methods (Ferrando *et al.*, 2020), to predict energy use and indoor and outdoor environmental conditions for groups of buildings (Chen and Hong, 2018). Many UBEM digital tools have utilized the EnergyPlus engine (Kamel, 2022) ("EnergyPlus", 2014), which as an open-source engine, is flexible and highly customizable (Kamel, 2022).

The minimum information needed for UBEM modeling and simulation includes building envelope and geometry data. Building envelope data is commonly assigned by using archetypes or reference buildings (Ali *et al.*, 2019). In contrast, simplified shoebox models or 3D models are used for geometry data, commonly at the level of detail 1 (LOD1) or 2 (LOD2). However, these models have important limitations (Parts *et al.*, 2023). For example, these models do not contain necessary information on windows and (recessed) balconies, which significantly impact solar heat gains, shading, or photovoltage panels (PV) placement on the façade (Wang *et al.*, 2022).

Many studies to generate geometry data for windows have been conducted (Dochev *et al.*, 2020; Orenga Panizza and Nik-Bakht, 2023). The common method to address this data gap is to use window-to-wall ratios (De Jaeger *et al.*, 2020), assigned to archetypes. Abolhassani *et al.* scaled all wall surfaces by the window-to-wall ratio to get window areas (Abolhassani *et al.*, 2022). This method is easy to implement but it frequently either underestimates or overestimates window areas (Dochev *et al.*, 2020) and fails to consider the actual positioning and orientations of windows. Furthermore, apartment buildings often do not have windows in all orientations, which is why this method is often too simplistic.

Johari *et al.* (2022) compared the shoebox, LOD1, and LOD2 geometry and the related effect of window placements and thermal zoning on heat gains. Additionally, they examined three main zoning configurations: 1 zone per building, 1 zone per floor, and 5 zones per floor. The results showed that during the cooling period of the year, the energy demands of LOD1 and LOD2 were significantly lower than those of LOD3 (18% and 13% respectively) (Johari *et al.*, 2022). For the heating period, the differences were dismissible.The effect of the orientation of windows was not thoroughly examined.

Generally, two distinct bottom-up physics-based UBEM study approaches can be distinguished (Kamel, 2022): (1) independent simulation (not considering surroundings) of multiple buildings and aggregation of results, and (2) studying the microclimate effects in a selected region. Most studies address either the first or the second area. The combined study is less common mainly due to the increased computational needs of simulating multiple buildings and surroundings together.

However, in an urban environment, solar radiation, air temperature, and wind speed loads are significantly affected by surrounding buildings, ground surface materials, and vegetation (Shareef, 2021). This is why some studies have focused on the combination of these approaches and have inspected the effect of urban microclimate in UBEM (Dougherty and Jain, 2023; Katal *et al.*, 2022; Liu *et al.*, 2023). These have focused on how weather influences buildings or how surrounding shadings affect buildings.

For example, one study created a dataset of wall center points of neighborhood buildings, with ground and roof heights stored as attributes (Faure *et al.*, 2022). The points were then utilized to regenerate shadowing objects. This allowed to regenerate objects within a 250m radius as shadows to the target building, lowering the computational cost. They found that at a district scale, differences below 2% could be achieved by including all shadowing building surfaces within a 50m radius from the building's centroid. (Faure *et al.*, 2022).

Another study developed a SketchUp plug-in (MOOSAS-FastSolar), where the shadowing effects were accounted for by two indicators: Surrounding Building Factor (SBF) and Impact Factor (IF). The SBF considers the height and length of the surrounding buildings and their distance from the target building, and IF describes the total shading effect on the energy demand of the target building (Wen *et al.*, 2022).

Due to the computational burden, shading effects of trees on building energy consumption have been assessed in fewer studies (Abdel-Aziz *et al.*, 2015; Zhu *et al.*, 2022, 2023). Simpson (2002) created lookup tables to provide a simple way of accounting for the effect of trees as shading objects. Still considering vegetation in addition to surrounding buildings should be examined further. With the climate pact (Directorate-General for Climate Action (European Commission), 2020) and the goal of incorporating more green areas in cities, the effect of the vegetation will likely increase.

Shading has a great impact on both building heat gains as well as PV production potential. Especially in higher latitudes where low sun angles result in more intense shadows (Formolli *et al.*, 2023). According to the new EPBD, solar energy installations will become the norm for existing residential buildings starting in 2033 if technically suitable and economically and functionally feasible. Currently, the assessment of PV potential often occurs without contextual considerations, even at the level of individual buildings (Formolli *et al.*, 2023). This is mainly due to the lack of requirements but also due to the lack of data and increased computational cost (Abdel-Aziz *et al.*, 2015; Zhu *et al.*, 2022, 2023). This simplification can result in disparities between real-world conditions and simulation models.

The research gaps presented above motivated us to plan and develop a workflow to tackle the data acquisition problem for UBEM. Specifically, this research focuses on two research gaps in the context of data acquisition: (1) LOD2 versus LOD3 geometry, and (2) the impact of surrounding buildings and vegetation. This case study aims to streamline and automate the integration of LOD3 geometry and building surroundings into building performance assessment. The workflow consists of gathering, preparing, and integrating data from various sources to enable modeling and simulation at the neighborhood level. The benefits of such workflow are demonstrated through a solar exposure study.

Research Methods

Workflow Development and Testing

The design research method (Hevner and Chatterjee, 2010) was utilized to develop the workflow in the context of the case study. The development of the workflow for neighborhood scale building performance assessment included the following phases:

- Information needs were specified based on the literature review.
- Data availability and sources were determined.
- Data was gathered, prepared, and integrated from different sources to enable UBEM modeling and simulation at the neighborhood scale.
- Data (specifically, point clouds for modeling trees and typology-specific geometry) templates were developed and integrated into a common workflow.
- The benefits are demonstrated in a case study through a solar exposure study.

Defining Information Needs

Sufficiently accurate information about the building geometry is one major challenge in energy performance assessment at the neighborhood level. Solar exposure is an important parameter influencing heat gains and on-site electricity generation. For this the following information is needed: target building geometry, surroundings (landscape, neighbor buildings, and trees), geographic information, the solar path across the sky (throughout the day and year), and climate and weather conditions (including direct and indirect solar exposure).

To assess solar exposure effectively, the surfaces need to be categorized based on building number, surface type (external wall, window, balcony railing, illustrated in Figure 1), surface orientation, and floor numbers. This identification allows to evaluate how the positioning and orientation of specific surfaces impact solar exposure, offering insights into variations across different surfaces at various heights. Additionally, this approach allows to exclude the north-facing facades, which lack direct solar exposure, from the overall average values. This can allow us to examine the surfaces that are most affected by solar exposure. Spaces with north-facing exteriors have a reduced risk of overheating compared to other orientations. In addition, they are usually not considered for PV installation.

The study considers the surrounding environment, incorporating both neighboring buildings and trees. The shapes of these elements serve as shading objects in the simulation. To accurately model solar exposure, the material properties of these shading objects must be considered. Particularly for trees, where the selected material accounts for light passing through the voxelated shapes.

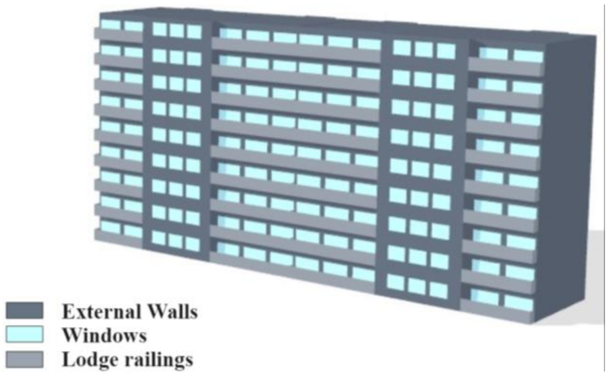

Figure 1: Vertical surfaces of the building.

Selected Pilot Site

An Estonian neighborhood (58°22' N Latitude, 26° 46' E Longitude) with 22 apartment buildings was chosen to develop and evaluate the workflow in the context of solar exposure study. The pilot area buildings represent one common Estonian archetype (Iliste, 2023): a typical not renovated apartment building with precast concrete external walls, built between the 1970s and 1990s. The main differences were in the number of floors and staircases, and orientation. It was also observed that all these buildings were constructed from different combinations of two staircase modules: (1) a side module, and (2) a middle module. This level of standardization makes them suitable for developing and applying geometry templates.

Table 1: Studied buildings' number of floors and staircases, and the neighborhood visualization from Estonian Landboard.

Building numbers	Number of floors	Number of staircases
12, 13	2	2
13	6	2
19	6	3
8	8	2
0, 1 ,2 ,3 ,4 ,5 ,6 ,7,9 ,10 ,11	9	2
20,21	9	3
15,16,17,18	9	4

Building Information and Geometry Template

General and technical information of buildings, LOD2 models, and design documents were acquired from the Estonian Building Register (EBR). It is a public database containing information for all Estonian buildings. It has an open data policy and web services to acquire data.

Geometry templates were developed to facilitate the generation of LOD3 models. For developing and constructing geometry templates, the dimensions of the buildings were acquired from floor plans and elevations of the buildings that had the design documentation available in EBR.

A geometry template is a 2D representation of a typical floor plan, consisting of a set of lines and points categorized according to their function or position (Figure 2). Two distinct templates were designed: (1) side module and (2) middle module. Each represents a staircase per floor and its apartments. Currently, the templates include one zone per floor and module. Additional details like internal walls could be added, which will be addressed within future research.

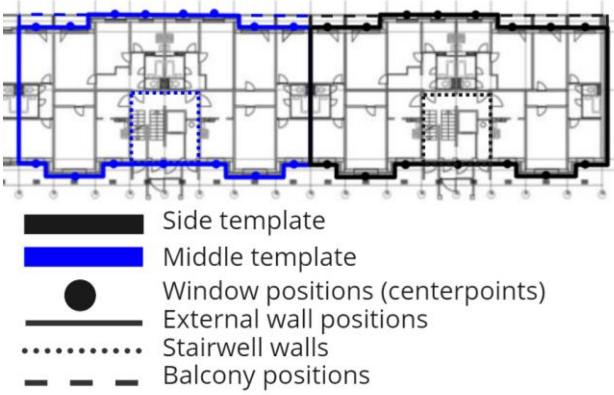

Figure 2: Extraction of geometry templates from design documents.

Point Clouds for Modelling Surrounding Trees

In addition to general and technical information of buildings, point cloud data were acquired from the Estonian Building Register (EBR). The point cloud data for the pilot neighborhood was acquired from EBR, processed, and segmented into landscape, trees, and buildings. The EBR LOD2 geometry, generated from LiDAR data, was used to position and orient the floor models to target buildings and to compare simulation results to current practices utilizing LOD1 or LOD2 models.

System Setup

An important issue in utilizing more detailed models and considering the surroundings is the computational cost. The simulations were run on a desktop setup: CPU: i7-13700 2.10 GHz, Graphic Card: Nvidia RTX A4500, Memory: 128GB. Rhinoceros software was chosen to develop the workflow. The built-in Grasshopper plug-in for visual programming was used to develop computational workflows. For the solar exposure study, the ClimateStudio plugin, utilizing the EnergyPlus engine, for Rhino was employed. For point cloud processing, trimming, segmentation, and conversion, CloudCompare was used.

Case Study Results

Workflow Development Criteria

The proposed workflow (illustrated in Figure 4) is divided into four phases: (1) Data Gathering and Aggregation; (2) Point cloud Processing, Segmentation, and Voxelization; (3) Generation of LOD3 Building Models; (4) Simulation and Visualization of Solar Exposure Study. The main criteria for developing the workflow included:

- **Integration of Existing Data Sources and Systems:** Ensuring seamless integration with existing data sources, systems, and tools to avoid redundancy, reduce manual data entry, and prototype the workflow.
- **Automation:** Automate gathering, preparing, and integrating data sources to reduce manual effort, minimize errors, and accelerate the overall workflow.
- **Flexibility and Scalability:** Ensuring the flexibility to adapt to changes in processes or requirements and accommodating growth.

In the following, the workflow phases and steps are described in detail.

EBR Data Gathering and Aggregation

The first phase involves data gathering and aggregation (see Figure 4). For the selected pilot site and its buildings, four types of data were gathered from the EBR and organized into a common database, including point clouds for the selected pilot site, design documentation, building LOD2 geometry, and EBR data on buildings. These data were acquired by directly downloading publicly available datasets or queried through EBR's open API services. The utilization of API services enables the automatization of data acquisition.

Point Cloud Processing, Segmentation and Voxelization

The second phase involved two steps for point cloud processing, segmentation, and voxelization to create the contextual information (See Figure 4 steps 2.1 and 2.2). For modeling and simulating shading effects on solar exposure, the airborne LiDAR (light detection and ranging) data available for the chosen neighborhood was acquired from the EBR. The point cloud was first separated into ground and non-ground measurements utilizing the cloth-based data filtering method (Zhang *et al.*, 2016), implemented in CloudCompare (Girardeau-Montaut, 2016). Second, off-ground points were categorized into buildings, trees, and rest through several iterations of applying statistical outlier filters, application of scalar fields (i.e., Planarity, Verticality, Sphericity), labeling of connected elements, and manual segmentation of clouds. The output was three separate sets of point clouds for ground, buildings, and trees in *.e57 file format.

Ground, buildings, and tree datasets were imported into Rhino, and the voxel method on trees' point cloud was applied to generate tree-like geometries. Different voxel sizes were tested and for this study, 1m voxel was used. The main criterion for this was the high computational cost of smaller-sized voxels. In the future, the impact of voxel size will be studied in more detail.

Generation of LOD3 Models

This phase involved two steps for generating LOD3 building models, including creating building archetype-specific geometry templates and floor models, positioning and orientating to the right location, and generating the entire LOD3 building model (Figure 4).

For creating a building geometry template, design documents for buildings in the selected pilot site were analyzed and two different basic modules were created: building side and middle modules. Depending on the number of staircases, these modules were aggregated into floor models. For example, a building with two staircases had only two mirrored side modules, building with three staircases had two mirrored side modules and one middle module between the two mirrored side modules (see Figure 3).

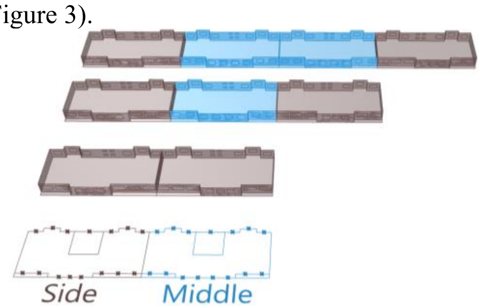

Figure 3: Geometry templates and aggregated floor models

After the creation of a floor model, it was positioned and orientated to the right location based on the LOD2 models from the EBR. After moving floor models to the right location, these were copied vertically as many times as the buildings had floors.

Simulation and Visualization of Solar Exposure Study

The fourth phase involved three steps for simulation and visualization of solar exposure results (see 4.1 – 4.3). In the first step, all previously generated data were integrated into a common simulation model.

In the second step, solar exposure simulations were performed for all 22 buildings of the selected pilot site. The study focused on assessing the impact of LOD3 geometry and the surrounding microclimate on solar exposure of buildings. Specifically, the focus was on vertical surfaces (external walls, windows, balcony railings see Figure 1) that are more likely to be affected by surroundings, especially when there is minimal variation in building heights.

Four solar exposure scenarios were established for simulations:

1. A LOD2 building in isolation (without surroundings).
2. A LOD3 building with detailed information on external walls, windows, and balconies in isolation (without surroundings).
3. A LOD3 building together with its surrounding buildings.
4. A LOD3 building surrounded by both other buildings and trees.

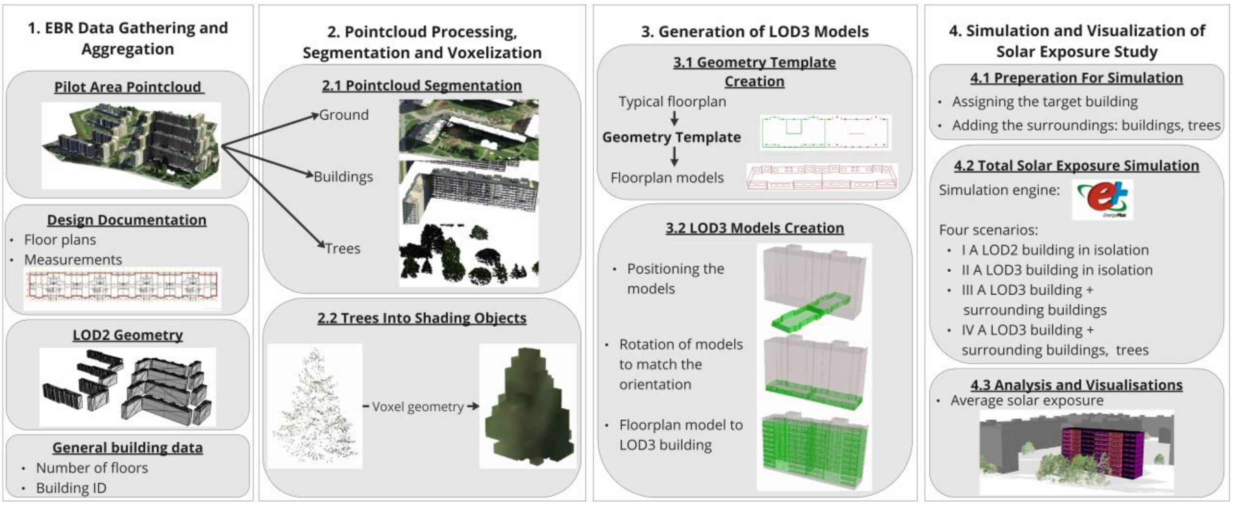

Figure 4: A workflow proposed and developed for neighborhood scale building performance assessment

In the first scenario, LOD2 geometry was employed. Sensor points were placed only on external walls since the LOD2 models lacked additional components such as windows and balconies. Surroundings were not considered. In the second scenario, solar exposure was simulated for walls, windows, and balconies, utilizing LOD3 building geometry. Similarly to the first scenario, the only shading object considered was the target building itself. In the third scenario, surrounding buildings were introduced as shading objects and used together with LOD3 building models. To optimize computational efficiency, LOD2 geometry was utilized for shading, while the target building retained LOD3 detail. In the fourth scenario, trees were incorporated as additional shading objects.

Demonstration: Solar Exposure Simulations

Solar exposure simulations were conducted for four scenarios and compared based on the total average solar exposure (kWh/(m²·yr)). North-facing surfaces were excluded, given their minimal exposure to solar. Climate Studio`s grasshopper plug-in was utilized for simulations.

Solar Exposure Comparison for LOD2 and LOD3 Models

In the first stage, a comparison between the average solar exposure of LOD2 (reference case) and LOD3 vertical surfaces was performed (see Figure 5). The LOD2 and LOD3 models for 22 buildings have similar side walls. Compared to the LOD3, LOD2 does not have different vertical wall, window, and balcony surfaces on the main facades, they are represented as a single surface. In this stage, the overall average values were compared: all vertical surfaces of the LOD2, and the average of all external walls and windows for LOD3.

The results revealed an average difference of 16% in solar exposure between the LOD2 and LOD3 geometry. The minimum difference between LOD2 and LOD3 buildings was 0% and the highest 47%. LOD2 overestimated solar exposure for buildings with the main facades facing East and West, while underestimating it for other buildings (Figure 5). For the East and West-facing buildings, the average solar exposure of LOD2 was 34% higher than LOD3. For North and South facing buildings, the average exposure of LOD2 was 1% smaller than LOD3.

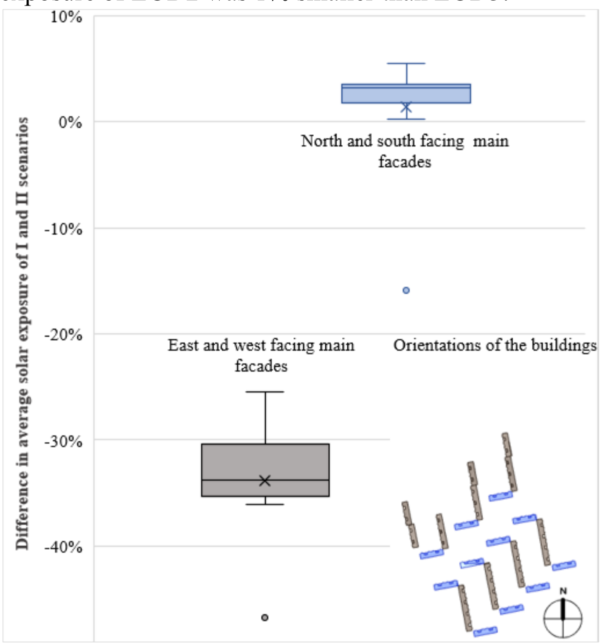

Figure 5: Difference in average solar exposure of scenario I (LOD2, reference case) and scenario II (LOD3).

These results demonstrate how the building's geometry level of detail impacts solar exposure. The main differences are in main facades. LOD2 simplifies main facades, excluding balconies (together with floors and railings), significantly influencing solar exposure on external walls and windows. This is why LOD2 overestimates the solar exposure for the East and West facing buildings.

For the North and South facing buildings, the South walls are side walls (similar for LOD2 and LOD3 geometry), receiving most of the sunlight. Also, these buildings have proportionally smaller main facades than East and West facing buildings have. This is why there are not that big differences in terms of solar exposure.

Solar Exposure Comparison Between II, III, and IV Scenarios

A comparative analysis was conducted for the second, third, and fourth scenario solar exposure results. Here, the second scenario was used as a reference case that the others were compared against.

Within these scenarios, three distinct surfaces were separately evaluated: (1) external walls, (2) windows, and (3) balcony railings. Additionally, the results were distinguished based on the floor level. Significant differences were observed on lower floors (see Figure 6). For the lower floors, the third and fourth scenarios exhibited a 17% and 27% reduction in solar exposure compared to the second scenario where only the target building without surroundings was considered.

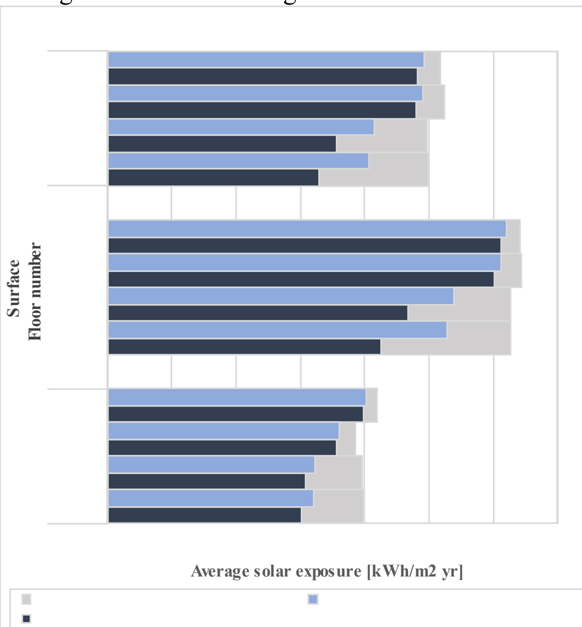

Figure 6: Variations in solar exposure across different surfaces and floors of lod3: scenario II (reference case) vs. scenarios III and IV.

When comparing the results of the three scenarios for higher floors, the disparities were minimal averaging only 4-6%. The average reduction in solar exposure over all the floors compared to scenario two was 12% for scenario three and 17% for scenario four.

The most substantial difference was observed in solar exposure on balcony railings with a notable 18% and 34% reduction on the first floor. This occurs because railings serve as shading objects for other surfaces (external walls and windows), while other components do not offer shading for the railings themselves.

Notably a small difference (3 % on average) in solar exposure between floors can be identified even when no surrounding objects are considered. This effect occurs due to the upper protruding parts of the façade being exposed to the sun before the rest of the façade (see Figure 7) but also when the protruding parts cast a shadow on the lower part of the façade leaving the upper parts exposed to the sun.

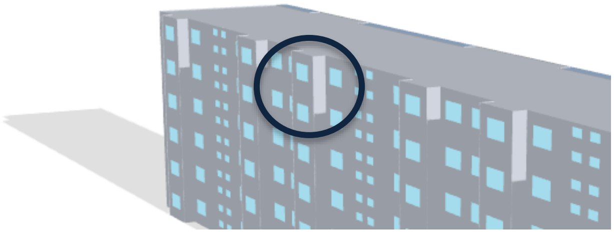

Figure 7: Early solar exposure on the upper protruding part of the facade.

Discussion

This case study approached the data acquisition problem in the field of UBEM by advancing data integration workflow. LOD3 geometry, surrounding buildings, and trees, as shading objects, were incorporated to facilitate neighborhood-level building performance evaluation. Solar exposure metric was used to assess the benefits of the developed workflow. Solar exposure is an important metric influencing many building performance aspects.

The utilization of geometry templates for highly standardized apartment buildings offers a simple solution to develop LOD3 models. Solar exposure analysis demonstrated a notable 16% difference between LOD2 and LOD3 geometry. The effect is mainly due to the incorporation of balconies that act as shading objects. This aligns with another study (Johari *et al.*, 2022) that demonstrated 18% and 13% lower energy demand for the LOD1 and LOD2 when compared to the LOD3.

Previous approaches to LOD3 creation have mainly relied on manual model creation, making it less cost-effective due to resource-intensive implementation. The main limitation of the geometry templates is their reliance on standardized solutions and designs. That is, geometry templates are most useful when there are multiple standardized buildings following the same design principle.

We also developed a workflow to simplify the incorporation of surroundings into building performance assessment and examined the benefits through a solar exposure study. We identified that the incorporation of surrounding buildings on average leads to a 17% reduction of solar exposure on lower floors, with an additional 10% reduction attributed to trees. The limitation of the solar exposure results is the exclusion of the north-facing facades. In future research, north-facing facades could be included to get a more comprehensive understanding.

Also, considering that the examined neighborhood was not intensely populated, these effects could be even more significant in more intensely populated areas. Some existing UBEM solutions have incorporated surrounding buildings but have disregarded trees due to the additional computational cost. This study demonstrated the need to also consider trees. However, the reliability of the developed approach and computational cost were not examined. This needs to be considered in more detail in future studies.

This case study primarily focused on workflow development and utilized solar exposure as an indicator to demonstrate its benefits. Future research could extend this work to include overheating modeling and simulation studies, additional shading requirements, heat gains, and their collective impact on building energy performance. This would allow us to further examine the benefits of accurate window placements and the impact of shading objects. Moreover, our developed workflow enables the incorporation of the ground surface. This could be also utilized for site analysis, for example, incorporating overflooding risk assessment.

Conclusions

This case study developed and demonstrated the utility of a data aggregation workflow for UBEM incorporating LOD3 models, surrounding buildings, and trees for building performance assessment at the neighborhood scale. Solar exposure was used to evaluate the workflow benefits. The proposed workflow was tested in a selected pilot site with 22 apartment buildings. The findings from our solar exposure study demonstrated the impact and need for LOD3 models of buildings with balconies and protruding façade elements. Additionally, it showed how the surrounding buildings and trees significantly influence solar exposure and consequently the reliability of UBEM workflows in general, ranging from the 0% difference between LOD2 and LOD3 to 47%. As a first step, this research contributes to the ongoing efforts towards renovation and digitalization as strategic measures for decarbonizing the European building stock by 2050. However, further studies regarding the reliability of typology-specific geometry templates and point cloud-based building trees are needed.

TRANSITION DYNAMICS IN RESIDENTIAL HEATING SYSTEMS: AN AGENT-BASED MODELING APPROACH

Xinyi Mu[1], Dujuan Yang, and Qi Han
[1]Eindhoven University of Technology, The Netherlands

Abstract

The urgent global need to reduce carbon emissions has intensified the focus on transitioning to sustainable energy solutions. Residential heating is a significant contributor to greenhouse gas emissions. As such, understanding the factors influencing this shift towards more sustainable heating solutions, such as gas-free heat pumps, is critical. This study employs an agent-based model (ABM) to examine the dynamics of adopting sustainable residential heating systems, with a special emphasis on the transition to a gas-free community. The model integrates individual household preferences, financial capabilities, environmental concerns, and social influences to understand the collective transition. The paper illustrated the methodology through a numerical simulation.

Keywords: Agent-based modeling, residential heating, energy efficiency.

Introduction

The imperative to curtail global carbon emissions has intensified the efforts to transition towards sustainable energy solutions. Among the significant contributors to greenhouse gas emissions, residential heating stands out, necessitating a profound shift towards environmentally friendly alternatives. For example, the Netherlands is ranked in the top 5 in the EU for per capita greenhouse gas emissions, largely due to residential heating, which contributes about 10% of national emissions (PBL, 2020). The predominant use of natural gas for home heating is a key factor (de Wildt et al., 2021).

The transition to a sustainable heating system faces challenges in collective decision-making. These challenges stem from varying priorities and constraints among homeowners, including economic considerations and personal preferences. The complexity increases with the need to align these diverse viewpoints for the community-wide adoption of sustainable heating solutions.

Traditional equation-based models (EBMs) have been widely used to predict the diffusion of energy technologies, however, their ability to capture the nuances of individual behavior and complex system dynamics is limited (Moglia et al., 2017). EBMs typically excel in forecasting aggregate behavior but often fall short in depicting interactions at the micro-level, which are crucial for understanding the intricacies of decision-making for energy-related investment.

Agent-based models (ABM) emerge as a robust alternative, addressing these complexities by facilitating a detailed and realistic representation of individual agents and their interactions within a socio-technical framework. ABMs offer an in-depth view of system dynamics, integrating agent heterogeneity, social behavior, and geospatial elements. They allow for an exploration of non-linear relationships and the impact of individual decisions, providing a comprehensive understanding of diffusion patterns at both individual and collective scales (Hansen et al., 2019; Hesselink & Chappin, 2019).

ABM's flexibility in simulating various scenarios helps in understanding the potential outcomes of different heating system implementations, considering the unique dynamics of the homeowner decision-making (Rahmandad & Sterman, 2008). This intricate decision-making process encompasses the delicate balance homeowners trike between economic incentives, environmental concerns, social pressures, and how individual preferences and constraints shape their decisions towards heating system investments. By simulating these varied decision-making processes, ABMs can capture the complexity and heterogeneity inherent in homeowner behaviors, providing insights that are often overlooked in traditional modeling approaches.

The motivation for this research stems from the urgent need to support the transition to sustainable heating systems in a way that is both environmentally beneficial and socially acceptable. By developing a model that simulates household decision-making processes and examines the influence of factors such as economic incentives and social influence, this study aims to contribute insights into the diffusion of sustainable heating technologies. Ultimately, the goal is to inform and guide effective planning strategies that can accelerate the adoption of sustainable heating solutions, aligning homeowner decisions with broader environmental objectives.

This paper begins with an overview of background and significance, then introduces the model in detail, including design, agent attributes, and decision-making processes. The subsequent section presents the simulation setup, execution, and findings, illuminating the model's insights into sustainable heating adoption. The next discussion section links these results to wider real-world implications, leading to a conclusion section that summarizes key findings and suggests avenues for further research.

Methodology

An agent-based model was constructed using the Mesa framework (Kazil et al., 2020) to examine the dynamics of adopting sustainable residential heating systems. This model is strategically designed to address the limitations commonly found in traditional equation-based models, namely their inadequate representation of individual behaviors and the static nature of social interactions

(Moglia et al., 2017; Natarajan et al., 2011; Rounsevell et al., 2012). This model brings agent heterogeneity into consideration, also adds spatial dynamics which traditional ones are hard to simulate. By integrating a detailed representation of household behavior within a socio-technical system, the approach aids in finding real-world emerging patterns to proposed heating solutions, thus enhancing the effectiveness of planning and implementation strategies.

Model Structure

Agents in the model are autonomous entities representing individual households. Each agent is characterized based on statistical distributions that reflect socio-demographic profiles and social clustering data, consistent with real-world demographics. The agents are programmed to evaluate and possibly adopt energy technologies at each simulation step, contingent upon their unique states and decision-making rules. These rules are algorithmic representations of how agents convert their internal states into actions.

The internal state of an agent encompasses a range of parameters such as income, savings, environmental concern, energy efficiency concern, and more. The state evolves as the agent interacts within its social network and makes decisions based on a utility function that integrates the Theory of Planned Behavior with the Net Present Value (NPV) of potential investments.

The Theory of Planned Behavior (TPB) (Ajzen, 1991, 2002; Schiera et al., 2019), which is a widely used human behavior theory, explains human behavior through three attributes: Attitude Toward the Behavior, Subjective Norm, and Perceived Behavioral Control. The intensity of the behavior and the individual's commitment to action are influenced by the weighted contributions of these attributes.

The utility function, which calculates the behavioral intention in this model, is weighted by the agent's attitudes toward each technology, perceived social pressure, and perceived behavioral control, alongside environmental and energy efficiency factors.

The environment provides a virtual space for agents to interact and includes resources such as energy technologies and market prices.

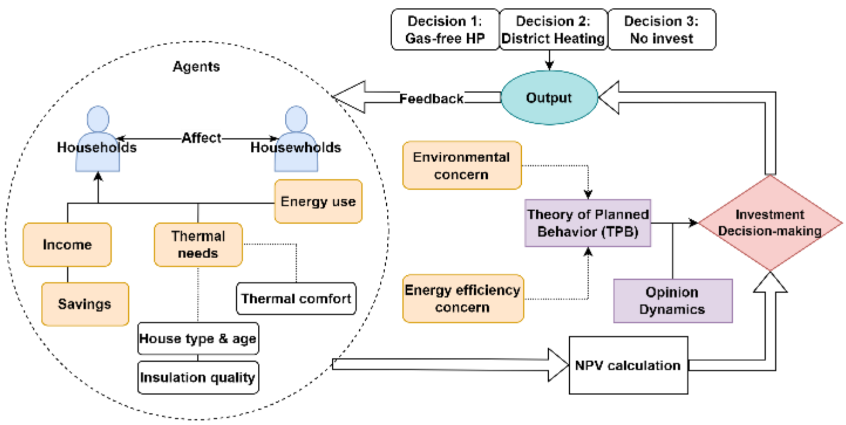

Figure 1. Conceptual ABM framework.

Figure 1 illustrates the conceptual ABM framework, where each household agent has some attributes: income, savings, energy use, and thermal needs. The thermal needs are influenced by house type, house age, the number and vulnerability of family members, and house insulation quality. The agents are faced with three primary decisions: to invest in a gas-free heat pump, district heating with gas, or to refrain from investing. These decisions are shaped by the agents' different concerns and the financial assessment. Feedback mechanisms are in place to reflect the evolving preferences and societal norms as agents interact and make investment decisions.

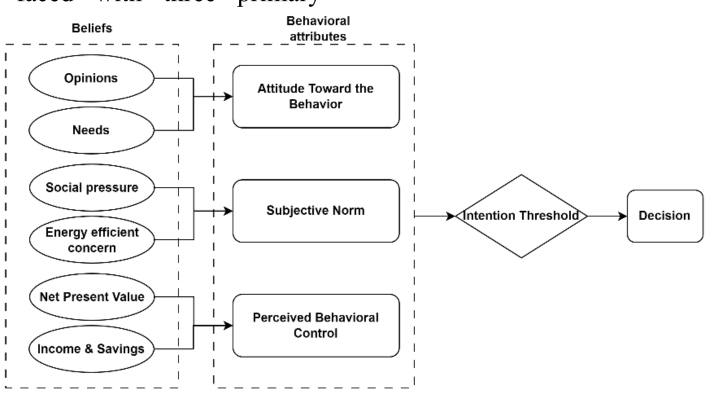

Figure 2. The behavioral sub model of decision-making process in the ABM model.

Figure 2 outlines the decision-making framework based on the Theory of Planned Behavior, which sets the decision-making rules for agents. The process begins with a range of input factors that influence an agent's beliefs, attitudes, and perceptions. 'Subjective Norm' is influenced by social aspects, such as the choices made by neighbors, reflecting the social pressure component. 'Perceived Behavioral Control' encompasses the agent's perception of the ease or difficulty of performing the behavior, which in this case could include financial constraints and thermal needs. The TPB weights are adopted from a survey conducted in the Netherlands (Niamir et al., 2018). Changing the weights would lead to different agents' behavior in the decision-making part.

These three constructs converge to form a 'Behavioral Intention' which is a critical determinant of whether the decision to invest will be made. If the value of this intention is higher than the intention threshold, the agent would decide to invest. Since there are two possible invest options in the model, only the one with higher value would be considered as household's decision. The decision is the final outcome of this process, indicating whether the agent will act on the intention to invest.

Decision-Making Process

To detail the model setting, the parameters adopted in the model is detailed in Tables 1 and 2. Table 1describes the difference between these investment options. Table 2 shows the parameters in the model, income and energy usage values are obtained from open-source datasets about the Netherlands, where N means normal distribution. These parameters collectively influence the final decision-making process.

Table 1. Comparison of Heating System Investment Options.

Attributes	Heat Pump*	District Heating	No invest/ keep original
Investment Cost	Very High	Medium	None
Energy Cost	Low to Medium	Medium	High
CO2 emission	Near Zero	Medium to High	Very High
Energy efficiency	High	Medium	Low
Lifespan	Around 15 years	Over 30 years	Around 15-25 years

***** Note: The Heat Pump category only includes gas-free options such as Air-source, Geothermal, or Solar Heat Pumps.

Table 2. Descriptions of Parameters/ Agent profiles in the model (euros). (Grimm et al., 2010; Müller et al., 2013)

Parameter	Value	Influence on Decision
	Household Characteristics	
Income (euros/m)	N(47120, 25210), Min: 3250 (*StatLine*, n.d.)	Determines investment capability
Environment Concern	N(0.35,0.1) (OECD, 2023)	Increases intention for environmentally friendly choices
Thermal Need	Calculate based on occupants and house situation	Affects the choices of heating systems
Occupants Number & Vulnerability	Uniform Integers [1,5]; See in Figure 3.	Influences thermal need
Insulation Quality	N(5,2)	Affects thermal need and perceived system efficiency
Energy Usage	N(2780, 1548), Positively clipped (Netherlands, 2023)	Affects energy costs and NPV calculations
	Investment Options	
Invest Costs	HP: 12000* DH: 4500	Upfront cost affects the decision
Net Present Value (NPV)	Calculated based on costs	Affects the long-term perceived benefits
Discount Rates	Calculated from interest rate	Used in NPV calculation
Energy Cost	Varies based on energy source	Affects running costs
Lifespan	HP: 15 years; DH: 30 years	Affects the discount rate and NPV calculation
CO2 Emission Factors	Varies by system type (Blum et al., 2010)	Impacts the environmental utility for each decisions

*Note: Initial costs, would change based on year used and energy cost.

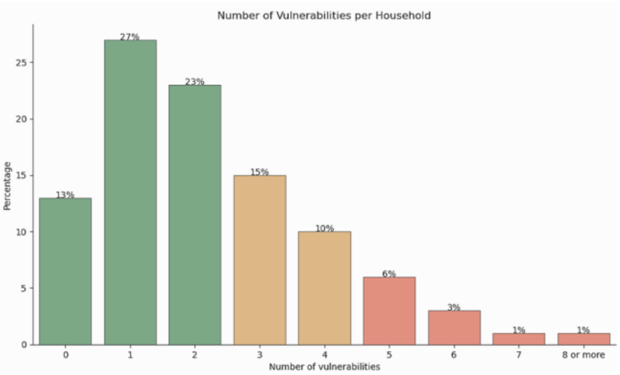

Figure 3. Number of vulnerabilities per household in the Netherlands. (*Many Dutch Are Doing Well, but for Some, Vulnerabilities Are Accumulating*, n.d.)

The thermal need is calculated by multiplying the number of occupants, the presence of vulnerable individuals, insulation quality with adjustment factors for house age, and heating system energy efficiency.

$$NPV = \sum_{0}^{t} (B_t - C_t)/(1+i)^t - C_0$$

The formula is for the calculation of Net Present Value. It calculates the present value of a series of benefits B_t minus costs C_t over a period t, discounted by the average annual bank interest rate i. C_0 is the initial cost.

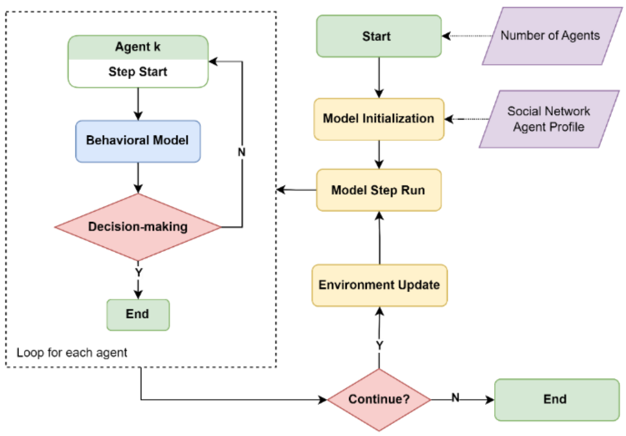

Figure 4. Decision-making process of the ABM framework.

The decision-making process is illustrated in Figure 4. The model is initialized with 1,000 households, each assigned a set of attributes, whose values are randomly generated based on the distributions, according to Table 2. The simulation runs over 15 steps in a loop, with each step representing a year. In each loop of the simulation, which represents one-time decision-making process, agents update their decisions based on various factors, including the recent choices made by their neighbors. This dynamic interaction introduces a layer of social influence, whereby the decisions made by an agent's neighbors in the current loop can affect the agent's own decision-making process in the same loop. Along with these social affects, households annually reassess and update their intentions and financial estimations, leading to potential changes in decision-making. Energy costs are also subject to an annual inflation rate, influencing the NPV calculations and thereby affecting investment decisions over time.

At each simulation step, results are collected on the number of households installing each heating system type and their corresponding investments. After running 15 steps, the agent decides on a heating system, which is the final of the simulation's set duration. This reflects the real-world scenario where investments in heating systems are long-term and rarely reversed. Post-simulation, the percentage of households opting for each heating system is calculated and analyzed to understand the prevailing trends and the impact of the considered factors.

Results

A numerical simulation has been performed in this study. The simulation demonstrates an increasing preference for gas-free heat pumps, indicating a collective inclination toward sustainable options. Heat pumps show higher adoption rates compared to gas district heating, as evidenced by the histogram distribution of final choices. The simulation results of 100 runs are presented below:

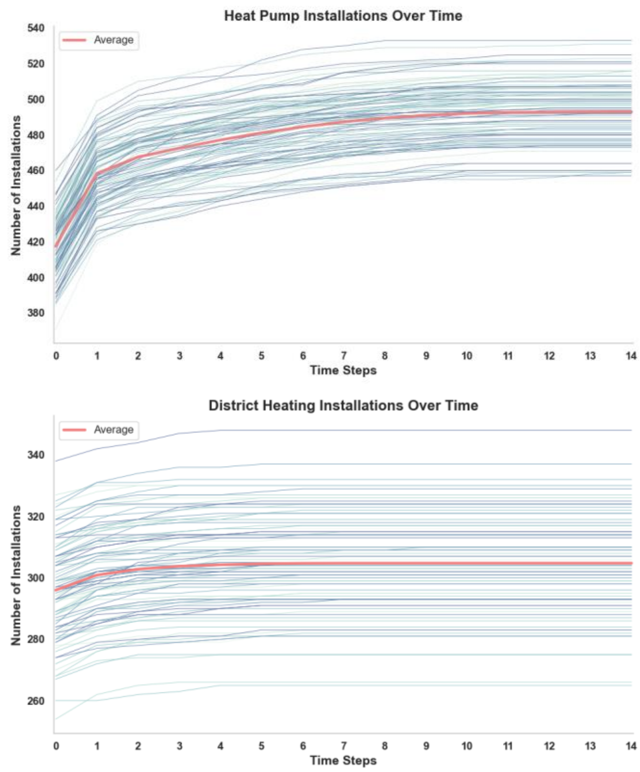

Figure 5. Installation numbers of each investment option across multiple simulation runs.

An upward trend for gas-free heat pump is evident, with a converging average suggesting a growing preference.

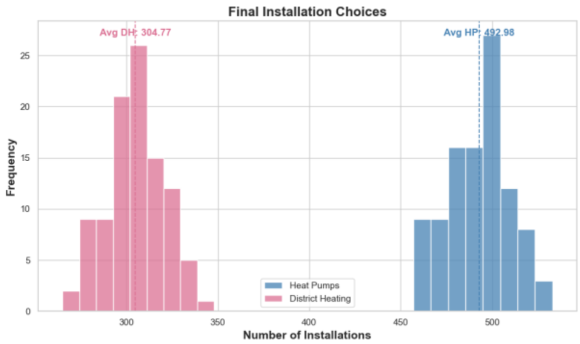

Figure 6. Final Installation Choices Histogram of the distribution of final choices.

Indicating a higher adoption rate for heat pumps over gas heating.

Table 3. Overall mean percentage of households' decisions.

Overall Mean Percentage in the Households		
Gas-free Heat Pump	District Heating	No Invest
49.30%	30.48%	20.23%

Discussion

The agent-based model's simulation process could reveal discernible patterns in household heating system decisions. The multi-objective nature of the model encapsulates the trade-offs between cost, efficiency, lifespan, and environmental impact.

There is a robust inclination towards gas-free heat pumps, despite their higher costs and reduced lifespan. This preference persists even when compared to gas district heating, which offers a longer lifespan and marginally improved efficiency than traditional separate heating systems but falls behind due to its CO2 emissions. The curve of district heating leveled off earlier, reflecting some residents' collective preference for cheaper, long-lasting district heating. The option to retain existing heating systems, which represent the least financial burden in terms of upfront costs but fail on efficiency and environmental grounds, is the least popular choice.

This outcome may signify an inherent bias within the simulation towards progressive environmental action. The bias is driven by the model's weighting of environmental concerns and a reflection of the agents' social pressure, where the adoption of greener technologies is perceived positively. This underscores the potential effectiveness of policy mechanisms, such as subsidies or carbon taxes, to steer communities towards greener alternatives, despite the associated costs and practicalities.

Moreover, the model offers a valuable tool for evaluating the influence of social norms and financial capabilities on the decision-making process. It highlights the critical role played by community behavior and collective environmental commitment in fostering the adoption of sustainable heating technologies. As such, the findings emphasize the interconnected nature of individual choices and broader community dynamics in the adoption of a more sustainable and environmentally conscious approach to residential heating.

Conclusion

This study applied an ABM to simulate the adoption dynamics of residential heating systems, focusing on gas-free heat pumps and district heating options. The model effectively captures the nuanced decision-making process of households in adopting heating systems. The model highlights the complex interplay between various factors that shape household decisions. It underscores the need for multi-faceted policy instruments that not only encourage the adoption of green technology but also address barriers related to cost and technology longevity.

Future research could focus on refining the model's parameters, building a more comprehensive real-world dataset to capture a broader spectrum of real-world behaviors, and integrating feedback loops that might emerge from widespread adoption of these technologies. Conducting a comprehensive sensitivity analysis is essential for validating the model. Furthermore, while the model captures individual decision-making within a physical neighborhood context—significantly shaped by social norms—it does not explicitly simulate collective decision-making scenarios. Such scenarios could include the influence of key decision-makers whose choices disproportionately impact the community's adoption patterns.

AN EVOLUTIONARY ALGORITHM-BASED MODEL PREDICTIVE CONTROL FOR COMBINED ELECTRICAL AND THERMAL ENERGY SYSTEMS

Sarah NOYE, Asier URUEÑA ANDREU, Ruben MULERO MARTINEZ,
Ricardo ALONSO SEGADE and Angel CARRERA MARTIN
TECNALIA, Basque Research and Technology Alliance (BRTA), San Sebastian, Spain

Abstract

Energy storage is crucial to increase renewable energy adoption in construction. By optimizing their control strategies, operational costs decrease and return on investment improves. Model Predictive Controls (MPC) have been used to optimize the use of energy storage but are costly to implement. This paper presents an MPC with a generalized mathematical model for electrical and thermal storage. A methodology is introduced to account for physical restrictions. Three evolutionary algorithms were compared for the optimization and a Genetic Algorithm was found to best reduce the energy bill with average daily savings of 38.7 %.

Introduction

Driven by decarbonization targets, there is a strong push for increased electrification of building thermal demand coupled with the drive for increased use of renewable energy produced on site. One of the main constraints of Photovoltaic (PV) self-consumption in residential buildings is that a significant amount of the consumption takes place when there is no PV generation. A potential solution to overcome this is energy storage, electrical or thermal, allowing to use the PV excess generated during the central hours of daylight to cover the demand at night and other instants without PV generation. To date, electrical storage has been favoured, but thermal storage can be an additional source for storing surplus PV electricity in buildings with considerably less costs than electrochemical batteries, increasing the self-consumption rate and ultimately, usability of the local resource which yields better economics for the PV system (Psimopoulos et al., 2016).

To shorten the payback time of energy storage systems, it is important to have a sound control strategy. Most building systems use rule-based controls, which have the advantage to be easy to implement and to transfer between buildings (Noye et al., 2022). However, in the case of energy storage, the efficiency of a control strategy depends on the relation between future production and consumption. The advances in data-driven predictive models (Zhang et al., 2021) mean that it is possible to move towards predictive control. Optimal economic dispatch strategies for prosumers with energy storage have been widely investigated and reported in the literature (Liu et al., 2023). Model Predictive Controls (MPC) have shown to be effective at optimizing control prediction (Sultana et al., 2017). They consist in finding the optimal control action based on the constraints defined by a model over a finite receding horizon. MPC formulations over a short period of time, typically a day, to make battery charging/discharging decisions at each time step have been widely used to address different operational scheduling challenges, like the dispatch of energy storage in microgrids (Shang et al., 2020), operation control of multiple battery energy storage systems (Kim et al., 2018), market participation of smart home aggregators (Correa-Florez et al., 2018), or demand response for heat pump assisted solar water heater (Zhao et al., 2023).

Most of the studies address either battery or thermal storage. Combining both technologies lead to increased control complexity, as the storage charge and discharge efficiency, and self-discharge rate differ between technologies, and are time depended in the case of the thermal storage. A single study has been found to address the joint optimization of electrical and thermal storage (Iwafune et al., 2017), where the additional savings from combining both storage technologies are clearly stated. However, results are conditioned by the selected use case, where PV generation stands for around 5 times the averaged consumption, leading to a huge PV surplus that limits the margin for optimization of MPC management strategies.

The main challenge of MPCs in obtaining a model formulation, including physical constraints, that is compatible with optimization techniques, which often means reducing the order of the model and thus its accuracy (Noye et al., 2022). Evolutionary algorithms have been gaining interest for MPC, as they are able to solve non-linear optimization problems with non-differentiable cost functions (see for example Rodríguez del Nozal et al. (2019)).

The present paper builds on top of previous work from this research group, where a scalable and flexible optimization system based on production and load forecasting as a MPC for electrical storage scheduling (Lloréns et al., 2021). In the present work, the main contribution is that both, electrical and thermal storage, are simultaneously considered to optimize their jointly use. A mathematical formulation for an MPC to optimally control a system with renewable electricity production, electrical and thermal storage, and thermal and electrical consumption is presented, together with its optimization via evolutionary algorithms. The reparation method has been improved compared to previous work (Lloréns et al., 2021), so that it provides an interval of possible value, instead of truncating the values to their limits, reducing the exploration capability of the algorithm.

In the following section, the optimization problem is presented before describing the methodology used for the optimization. The methodology is divided between the mathematical formulation of the optimization problem and the methodology to solve it. The test case and how it was implemented is then described before presenting and discussing the results of the study.

Optimization problem definition

The considered system is composed of the following elements: electrical production, electrical and thermal storage, electrical and thermal consumption. A Heat Pump (HP) is used to charge and discharge the thermal storage. Figure 1 illustrates the energy flux between the different elements of the system. The aim of the MPC is to exploit the flexibility potential provided by the thermal storage and the electrical battery to maximize the use of local energy sources.

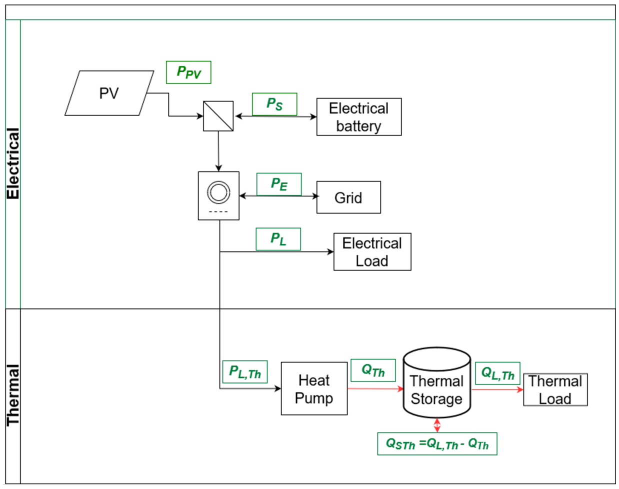

Figure 1: Main energy fluxes of the conceptual energy system to control

Methodology

Figure 2 illustrates the general schema of the MPC presented in this paper. First a general mathematical formulation of the problem is developed based on physical equations. It is divided in three sets of equations: 1) A cost function that represents the objective function to minimize; 2) A set of constraints to ensure the solutions of the optimization are viable; 3) A set of equations that link the different variables necessary for the calculation of the cost and the restrictions between time steps.
Evolutionary algorithms, a category of meta-heuristic optimizations, are then explored to find the optimal solution of the mathematical optimization problem. Three algorithms were compared: Estimation of Distribution Algorithm, Differential Evolution and Genetic Algorithm. The inputs of the optimization process are, on one hand, forecasting data (P_L the electrical load, P_{PV} the photovoltaic production, $Q_{L,Th}$ the thermal load and T_{amb} the outdoor ambient temperature) and, on the other hand, the current

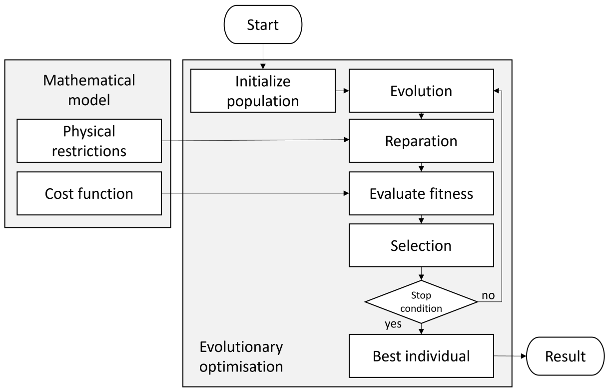

Figure 2: Overview of the MPC architecture

state of the system (charge of the battery SoC_{ini} and of the thermal accumulator $SoC_{ini,Th}$).
The optimization variables are the optimized values for charge and discharge of both the electrical battery (P_S) and the thermal storage (Q_S) for the N next time steps.
A baseline calculation, based on a rule-base reactive control sequence, is done in parallel to evaluate the performance of the evolutionary optimization process.

Mathematical model formulation

This section describes the mathematical formulation of the MPC control. It results in a cost function and a set of constraints used by the optimization algorithm.

Cost function

The mathematical definition of the optimization problem is based on the balance of electrical and thermal energies in the system. The convention used in this paper is that the positive numbers correspond to discharge actions and negative numbers to changer actions. For the electrical part, the energy balance can be expressed as follows:

$$P_{PV}^n - P_L^n - P_{L,Th}^n + P_S^n + P_E^n = 0 \qquad \forall n \in \{1,\ldots,N\} \quad (1)$$

Where P_{PV}^n is the PV production, $P_{L,Th}^n$ the electrical load of the heat pump, P_L^n the remaining electrical load, P_S^n the electricity charged (<0) or discharged (>0) from the battery, and P_E^n the electricity drawn from (>0) or injected to (<0) the electricity grid. n represents the time steps of the control system and N the optimization period.
The thermal energy balance is expressed as follows:

$$-Q_{Th}^n - Q_{L,Th}^n + Q_S^n = 0 \qquad \forall n \in \{1,\ldots,N\} \quad (2)$$

Where Q_{Th}^n is the thermal load of the system, $Q_{L,Th}^n$ the thermal energy produced by the heat pump (always <0), and Q_S^n the energy extracted (>0) or injected (<0) from the thermal storage.
The thermal and electrical equations are coupled by the heat pump performance, which is:

$$P_{L,Th}^n \cdot COP = -\,Q_{Th}^n \quad (3)$$

Where COP is the heat pump's Coefficient of Performance (COP), which is a function of both the storage temperature and the ambient temperature.
Combing Equations 1, 2 and 3, the equation of the conservation of energy is formulated as follows:

$$P_{PV}^n - P_L^n - \frac{1}{COP}(Q_{L,Th}^n - Q_S^n) + P_S^n + P_E^n = 0 \quad (4)$$

The objective of the MPC is to maximize the rate of self-consumption of the whole building, which is equivalent to minimizing the energy imported from the grid P_E. To maximize self-consumption, importing electricity need to be avoided, which corresponds to ($P_E > 0$). Thus the objective function to minimize becomes:

$$\sum_{n=1}^{N} \max\left\{0, (P_L^n + \frac{1}{COP}(Q_{L,Th}^n - Q_S^n) - P_S^n - P_{PV}^n)\Delta t\right\} \quad (5)$$

The use of the maximum condition between 0 and P_E avoids the exported electricity to be considered in the cost function and results in minimizing the imported electricity. One limitation of this cost function is that it does not account for the energy stored in the system within the optimization period, and would thus tend to discharge the battery. In addition, the cost function of Equation 5 does not differentiate between a solution with more energy stored in the system at the end of the period and one with an empty storage. To include this effect, the energy stored at the end of the period, weighted by a factor, is added to the cost function. The function to minimize becomes:

$$\sum_{n=1}^{N} \max\left\{0, (P_L^n + \frac{1}{COP}(Q_{L,Th}^n - Q_S^n) - P_S^n - P_{PV}^n)\Delta t\right\} - \alpha_1 \cdot Cap_{\max} \cdot \left[SoC^N\right] - \alpha_2 \cdot Cap_{\max,Th} \cdot \left[SoC_{Th}^N\right] \quad (6)$$

Where Cap_{max} is the net capacity of the electrical battery, SoC^N the State of Charge (SoC) of the battery at the end of the optimization period, $Cap_{\max,Th}$ the net capacity of the thermal storage, SoC_{Th}^N the SoC of the thermal storage at the end of the optimization period, α_1 a positive weighting factor for the electricity stored at the end of the period, and α_2 a positive weighting factor for the thermal energy stored at the end of the period. The drawback of this addition is the loss of physical meaning of the cost function.

Constraints

To ensure that the cost function leads to solutions that make physical sense, six constrains are introduced. The first two equations ensure that the charging and discharging of the battery meet the available battery capacity, one for the maximum capacity and the second for the minimum. The restriction on the discharge of the battery is expressed analytically as:

$$P_S^n \leq \psi_S \frac{cap_{max}(SoC_{ini} - SoC_{\min})}{\Delta t} - \psi_S \sum_{k=1}^{n-1} (min(0, P_S^k \psi_S) + max(0, P_S^k \frac{1}{\psi_S})) \quad (7)$$

And for the charge of the battery the restriction is:

$$-\frac{1}{\psi_S}(\frac{cap_{max}\Delta SoC}{\Delta t} - \frac{cap_{max}(SoC_{ini} - SoC_{min})}{\Delta t} + \sum_{k=1}^{n-1}(min(0, P_S^k \psi_S) + max(0, P_S^k \frac{1}{\psi_S}))) \leq P_S^n \quad (8)$$

Where ψ_S is the battery efficiency, SoC_{ini} the battery SoC at t=0, $SoC_{\min}$ the minimum allowable value for the battery SoC, and ΔSoC the allowed range for the battery SoC.
Similarly, two restrictions ensure that the charging and discharging of the thermal storage keep the tank operation in the allowed range. For charging, the equation is:

$$Cap_{max,Th} - Cap_{max,Th} SoC_{ini,Th} + \Delta t \sum_{k=1}^{n-1} (Q_S^k + G(T_{Tank}^k)) \geq \Delta t \cdot Q_S^n \quad (9)$$

And for discharging:

$$Cap_{\max,Th} SoC_{ini,Th} - \Delta t \cdot \sum_{k=1}^{n-1} (Q_S^k + G(T_{Tank}^k)) \geq \Delta t \cdot Q_{S,Th}^n \quad (10)$$

Where $SoC_{ini,Th}$ is the thermal storage's SoC at t=0, and $G^k(T_{Tank})$ a function of the tank temperature T_{Tank} that accounts for the thermal losses of the storage.
The fifth restriction limits the power available to charge and discharge the storage to the heat pump maximum capacity ($Q_{Th,max}$):

$$0 \leq Q_{L,Th}^n - Q_S^n \leq Q_{Th\_\max}^n \quad (11)$$

Finally, the sixth restriction limits the power requested from the grid to the maximum power (by contract), constraining the flow in or out of the battery by:

$$-P_L^n - P_{L,Th} + P_{PV}^n + P_S^n \geq -pow_{\max} \quad (12)$$

Where $pow_{\max}$ is the contracted electrical capacity.

Relations between time steps

The additional equations presented in this section are used to calculate how the two SoCs and thermal storage temperature are affected by charge and discharge of the energy system between time steps. For the SoC of the thermal storage, the temporal relationship is:

$$SoC_{Th}^{n+1} = SoC_{Th}^n - \left(\frac{Q_S^n - G\left(T_{Tank}^n\right) \cdot \Delta t}{Cap_{max,Th}}\right) \quad (13)$$

The tank temperature in the next time step is:

$$T_{Tank}^{n+1} = T_{Tank,min} + SoC_{Th}^{n+1} \cdot (T_{Tank,max} - T_{Tank,min}) \quad (14)$$

Where $T_{Tank,max}$ and $T_{Tank,min}$ are the maximum and minimum temperature allowed in the tank respectively. For the battery, the update of the SoC between time steps is:

$$SoC^{n+1} = SoC^{n} - \frac{\psi_s \cdot \min\left(0, P_S^n\right) + \left(\frac{1}{\psi_s}\right) \cdot \max\left(0, P_S^n\right)}{Cap_{max}} \quad (15)$$

Control optimization

Evolutionary algorithms

Evolutionary Algorithms are heuristic algorithms based on the Darwin evolution theory known to be efficient at solving complex optimization problems. They are easy to implement since the fitness function does not need to be differentiable. They are based on a population that is evolved stochastically to look for better solutions. Because they are good at keeping diversity, they perform well when it comes to escaping local optimum. Three evolutionary algorithms were tested for the MPC: Estimation of Distribution Algorithm (EDA), Differential Evolution (DE) and Genetic Algorithm (GA).

EDA it is an evolutionary algorithm that focuses on building and updating probabilistic models of promising solutions to guide the search for optimal solutions in optimization problems. DE is an algorithm that optimizes a population of candidate solutions by iteratively combining the differences between their parameter values to progressively converge toward the optimal solution. GA mimics the process of natural selection by iteratively evolving a population of candidate solutions by selecting, recombining, and mutating individuals to find optimal solutions in optimization problems.

Individuals definition

Common to all the algorithm implementation is the definition of the individuals. A solution is represented by a 2N array, where the N first values represent the battery control P_S^n and the N following values, the tank control Q_S^n:

$$\{P_s^0, P_s^1, \ldots, P_s^{N-1}, Q_{s,Th}^0, \ldots, Q_{s,Th}^{N-1}\} \quad (16)$$

Population initialization

An evolutionary algorithm starts by generating an initial population of individuals. Because of the restrictions, a random individual is likely not to be valid. Indeed, the possible values for P_S^n y Q_S^n are constrained by the previous values and how they have affected the SoC of the electrical and thermal storage respectively. A sequential sampling initialization process that incorporates the restrictions was implemented starting from the initial state $x_0 = x(t_0) = (SoC^0, SoC_{Th}^0)$ and where P_S^n y Q_S^n depend on P_S^{n-1} and Q_S^{n-1} respectively.

According to the restrictions on charge and discharge of the electrical and thermal storage (Eq. 7-10) the valid range for P_s^n y Q_s^n (the values at the next time step) is as follows:

$$P_s^n \in [-Cap_{max}(1 - SoC^{n-1}), Cap_{max}(SoC^{n-1} - SoC_{min})] \quad (17)$$

$$Q_s^n \in [-Cap_{max,Th}(1 - SoC_{Th}^{n-1}), Q_{L,Th}^n] \quad (18)$$

In physical terms, this means that for discharge, the valid values are those smaller than the energy available at the accumulator and battery, and for charging the valid values are limited by the capacity available in the storage. Besides, for the thermal accumulator the discharge cannot be larger than the thermal load.

Substituting the equation of restriction of maximum load of the thermal storage (11) in (18) gives:

$$Q_s^n \in [max(-Cap_{max,Th}(1 - SoC_{Th}^{n-1}), Q_{L,Th}^n - Q_{Th,max}), Q_{L,Th}^n] \quad (19)$$

And finally, substituting Equation 12 that restricts the maximum load of the electric battery in (17), gives:

$$P_s^n \in [max(-Cap_{max}(1 - SoC^{n-1}), P_L^n + P_{L,Th}^n - P_{PV}^n - pow_{max}), Capmax(SoC^{n-1} - SoC_{min})] \quad (20)$$

Equations 19 and 20 define the range of valid values. Because they are coupled by $Q_{L,Th}$ and $P_{L,Th}$, first a uniform random sampling is performed to determine the value of Q_S^n. The value of P_S^n is then uniformly sampled within the resulting range.

Evolution process

The evolution process is implemented according to the three algorithms tested. For the EDA, the EMNA algorithm proposed by Teytaud and Teytaud (2009) was implemented. It consists in re-weighting to remove bias, which is aimed at limiting premature convergence. The main hyperparameter is the λ which is the number of individuals retained at each generation.

For the DE, the original algorithm from Storn and Price (1997) has been implemented where vectors are recombined based on the trial vector that is a linear recombination of random vectors of the population. The main hyperparameter is the scaling factor β which determines the weight of the selected vectors compared to the individual that is being evolved.

The GA implements a Gaussian mutation of mean $\mu = 0$ and deviation σ and a uniform crossover which is a commonly used implementation according to the review of GA by Katoch et al. (2021).

As for the initial generation of the population, the evolution process might generate invalid individuals. Several approaches exist to address this problem: 1) Define a specialized operators so that the evolution process only produces valid solutions; 2) Include a penalty for invalid solutions in the fitness function. One limitation of this approach is that the algorithm then works on reducing the penalty and might not focus as much on the optimization objective; 3) Introduce a repair operator that transforms invalid solutions into valid solutions.

Approach (3) was implemented using Equations 19 and 20. When the value at n violates one of the constraints, the individual is repaired sequentially at all the time steps between n and N. This enables to keep diversity in the population despite the reparation process.
The fitness of the generated individuals is evaluated using the cost function defined in Equations 6. It is used to build a ranking of individuals and select among them which ones progress to the next generation.

Baseline definition

To assess the performance of the optimization strategy, a static control strategy was defined using a set of rules. This strategy consists in a basic sequence that, in case where there is a PV surplus, it is stored in the battery, and once this is full, the system starts filling the thermal storage through the heat pump. Once both storage are full, it sends the surplus to the electricity grid. In the case there is no PV surplus, the system uses, if possible, the energy available both at the battery and the storage, and if they are empty, it will use electricity from the grid. This control strategy is evaluated for each individual in the optimization process, to compare to the evolutionary algorithms' results.

Implementation

This section describes the implementation of the MPC descried in the previous section and the test case that was used to test it. The mathematical model was implemented in Python, and the DEAP python library was used to implement the evolutionary algorithms.

Test case

The test case is based on a real multi-family building located in Pasaia, Spain. The energy system to be controlled has two central air-to-water heat pumps with a total heating power of 34 kW at nominal conditions with a thermal storage of 2.000 litres located in the building garage. From this centralized system, a low temperature (30º C) distribution loop runs through the building to the individual water-to-water heat pumps located at each of the dwellings to provide heating and Domestic Hot Water (DHW). Besides, there is a 6 kWp PV system on the roof and an electrical battery for storage.
The controlled system does not include the storage for the DHW linked with the water-to-water heat pumps at each of the dwellings. They offer limited flexibility potential (less than 2 kWh compared to close to 70 kWh for the central storage) while including them would significantly add to the computational complexity. This means an increased computational effort, poorer performance, more expenses in monitoring and control and in general, a less robust implementation.

Heat pump and water tank models

The *COP* and the thermal losses of the tank use equations specific to the use case. Those are characterized by a correlation that is a function of the tank temperature and the ambient temperature. For the COP, the following function was used:

$$COP = 10.168 - 2.716{\cdot}10^{-1} \cdot T_{Tank} + 4.331{\cdot}10^{-2} \cdot T_{amb} + 2.372{\cdot}10^{-3} \cdot T_{Tank}^2 - 6.623{\cdot}10^{-4} \cdot T_{amb}^2 \quad (21)$$

This correlation was obtained from data generated by a simulation of the system in TRNSYS, where the heat pump was modeled by a performance map obtained from the manufacturer data. This correlation could be updated by monitoring data from the system if available.
$G(T_{Tank})$ is a function that characterizes the thermal losses of the water tank. To obtain it, a thermal storage with cylindrical geometry and insulated according to the regulatory specifications was modeled in TRNSYS. The function was obtained preforming a correlation of the results of simulations of this model:

$$G(T_{Tank}) = (3.6 + 1.9 \cdot Vol) \cdot (T_{Tank} - 15) \cdot 10^{-3} \quad (22)$$

Where Vol is the tank volume in m³ and T_{Tank} is the tank temperature in °C.

Test case parameters

The optimization horizon N was selected to be 24 hours with time steps Δt of 1 hour.
In the cost function, the value of α_1 was set to $0.9 \cdot \psi$, and the value of α_2 to 0.9/3.5, where 3.5 is a proxy of the heat pump average COP. The motivation for the 0.9 value was to give a slightly higher value to the energy already consumed than the one stored for the next day.
The values of the physical parameters of the system are summarized in Table 1. The value of the heat storage capacity was calculated from the sensible heat capacity of water as:

$$cap_{max,Th} = \frac{4.18 \cdot Vol \cdot (T_{Tank,max} - T_{Tank,min})}{3.6} [kWh] \quad (23)$$

Optimization inputs

To test the validity of the developed MPC, one year of synthetic input data were generated. The hourly production were generated with PVGis for the location of the building. The TMY weather file generated by PVGis was used as well for generating the ambient temperature, to ensure consistency between radiation and temperature data. The hourly thermal load data were generated based on the historical natural gas invoices of the occupants. From these invoices, the summer consumption was accounted as representative of the DHW load, and the rest of the consumption was accounted as space heating. To generate hourly values of DHW load, the software DHWCalc 2.0 was used, imposing that the yearly load fits the value estimated from the invoices. For the space heating, the generation of hourly loads from annual values was done by allocating the operation of the thermostat in a minute basis based mainly on ambient temperature, hour of the day, a setpoint temperature and radiator capacity. The profile is subject to fit the amount of energy derived from the natural gas invoices.

Table 1: System parameters of the test case

Parameter	Value
Battery capacity (cap_{max})	6 kWh
Valid SoC range for the battery (ΔSoC)	0.8
Battery minimum SoC (SoC_{min})	0.2
Battery charge/discharge efficiency (Ψ)	0.95
Maximum storage temperature ($T_{Tank,max}$)	55 ºC
Minimum storage temperature ($T_{Tank,min}$)	25 ºC
Accumulator volume (Vol)	2 m³
Storage capacity ($cap_{max,Th}$)	70 kWh
Heat pump maximum capacity ($Q_{th,max}$)	18 kW
Maximum electricity consumption (pow_{max})	18 kW

Table 2: Days selected for the evaluation of the optimizer

Quantile	Date	PV/Load ratio	Total load (kWh)
0	16/01/2022	0.04	46.12
0.1	07/03/2022	0.32	24.85
0.2	15/11/2021	0.59	15.97
0.3	09/12/2021	0.77	36.22
0.4	25/04/2022	1.06	18.19
0.5	06/05/2022	1.74	9.03
0.6	01/07/2022	2.03	8.68
0.7	01/08/2022	3.22	8.12
0.8	07/05/2022	2.59	12.99
0.9	06/09/2021	4.29	6.41
1	06/07/2022	4.45	7.83

The initial daily SoC were set to 0.6 for SoC_{ini} and 0.5 for $SoC_{ini,Th}$, so as to be in the middle of the range between minimum and maximum charge.

Test days

To select the best algorithm, a set of days representative of the different boundary conditions were selected. Since the optimization potential is strongly affected by the PV production and the thermal and electrical loads, the ratio between the PV production and the system load was used. After evaluating the metric for all the days in the test data, the days were ordered and days on the quantiles were sampled in increments of 0.1 (Table 2).
The days with a low PV/Load ratio have a high demand compared to the PV production, when the days with a high PV/Load ratio have a lot of production compared to the demand. The days with the most optimization potential are the ones where the PV/Load ratio is more balanced. The optimization results of the best algorithm were then evaluated on the full year.

Discussion and result analysis

Evolutionary algorithm selection

Several configuration were tested on the 10 reference days for the different algorithms. For the EDA, several values of λ between 300 and 1200 were tested. They were found to have a very small influence on the final results. Although the EDA gave acceptable results some days, there were days when it did not manage to improve on the baseline, mostly in days with a low PV/Load ratio. For the DE, different values of the scaling factor β were tested. Lower values of β performed better, but the DE got stuck in a local minimum and complexity would need to be added to the algorithm to increase its exploration rate, in order to have satisfactory results. For this reason and although the EDA and the DE could be improved to palliate their initial limitations, the GA was selected as the best algorithm as a basic implementation would give better results than the baseline.
For the GA, the main hyperparamters tested were the selection method and the σ value. The most important factor for the GA to find better solutions than the baseline is the selection of individuals that pass to the next generation. With the roulette method the GA converges in a local minimum and fails to improve the baseline, whether the tournament selection method enables to improve the baseline. Finally, σ was found to have a small influence on the results, and only affect the optimization outcome on the days with more solar production than demand. The final value selected is 0.5.
Once the GA algorithm was selected, some experiments have also been carried out to determine the best population size and optimal number of generations. It was found that 200 was generally a good number for both. Table 3 shows that the best individual is generally identified between generations 157 and 200. Even in the cases where the best individual was generated in the generation 200, it was found that running the optimization longer would only marginally improve the result.

Optimization results

This section summaries the optimization results obtained with the MPC with GA optimization. Table 3 shows the

Table 3: Results of the genetic algorithm for the test case

Date	PV/Load ratio	Total load (kWh)	Cost GA	Cost baseline	Absolute savings	Relative savings %	Best individual's generation
16/01/2022	0.04	46.12	30.47	30.12	-0.35	-1.17 %	179
07/03/2022	0.32	24.85	4.27	4.66	0.39	8.39 %	165
15/11/2021	0.59	15.97	-5.19	-3.56	1.64	46.00 %	191
09/12/2021	0.77	36.22	0.78	3.14	2.36	75.14 %	199
25/04/2022	1.06	18.19	-8.21	-8.10	0.11	1.31 %	198
06/05/2022	1.74	9.03	-15.59	-13.76	1.83	13.33 %	178
01/07/2022	2.03	8.68	-17.59	-17.39	0.21	1.20 %	187
01/08/2022	3.22	8.12	-21.69	-19.88	1.81	9.10 %	198
07/05/2022	2.59	12.99	-23.04	-18.99	4.06	21.36 %	200
06/09/2021	4.29	6.41	-23.39	-19.57	3.82	19.52 %	157
06/07/2022	4.45	7.83	-20.90	-21.21	-0.31	-1.48 %	199

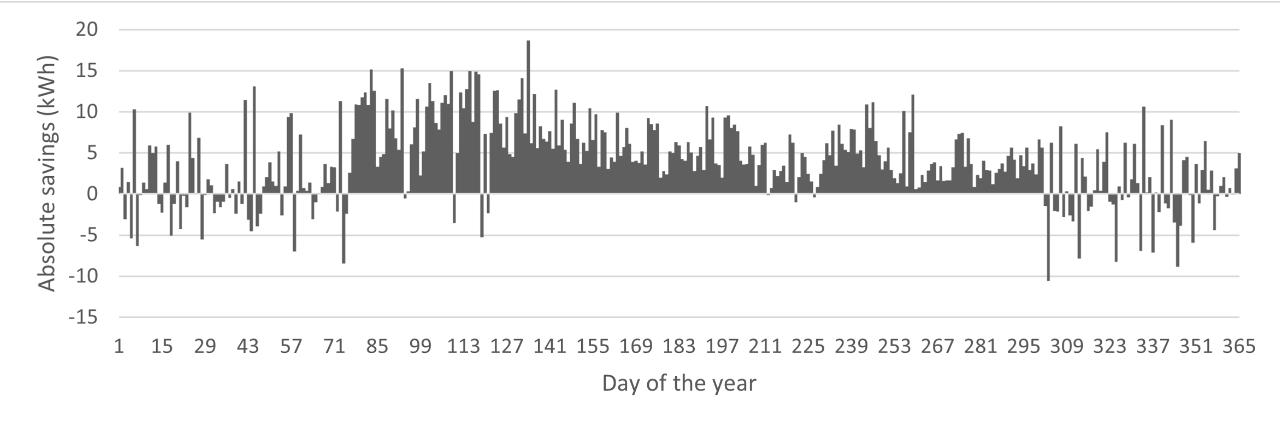

Figure 3: Daily absolute saving over one year

savings achieved for the 10 representative days. The absolute savings are difficult to interpret due to the additional term added to the cost function which makes it lose its physical meaning. Relative savings were thus calculated as the percentage of absolute saving compared to the cost of the baseline.

It can be seen that for two of the selected reference days, the MPC yields a performance under the baseline definition. Those days correspond to the limit cases. The 16/01, there is almost not PV production while the load is high. The 06/07, the demand is limited while the PV production is high. In both cases, there is no potential for optimization and the baseline provide the optimal solution. In those cases the GA failed to converge to the baseline. This can be solved in practice by implementing a control rule that does only run the MPC when there is optimization potential.

Two of the representative days have savings that are lower than 2 %. The 25/04 the demand during the hours with PV production is very close to the production, meaning the optimal solution is to consume the PV energy as it is produced leaving little room for optimization. The 01/07, the lack of optimization reserve comes from the fact that the pick of demand is before the period of PV production and the rest of the days then corresponds to a case with high solar production and no demand.

For the rest of the days (7 out of 11), the MPC is able to leverage the combined electrical and thermal storage much better than the rule base system.

Figure 3 shows the daily saving (without the additional term) that the MPC achieves compared to the rule base control. It can be seen that the MPC yealds less interesting saving in the winter month (beginning and end of the year) where there is statistically less solar production, but provides good results the rest of the year. Over the year 1454.23 kWh less is imported from the grid, which represents an average of 38.7 % of daily saving compared to the baseline. This could be further improved by using the baseline when it yields better results.

The MPC has been developed with PV in mind because of the test case at hand, but the mathematical formulation remains valid for any other electrical production (e.g. micro wind generation). The optimization results would need to be validated as the pattern between production and consumption would be different. Similarly, the formulation stays valid for a case where there is only one of the two storage types. In this case, the values of the system that is not present can simply be put to be zero.

Conclusions

In this paper, an evolutionary algorithm-based MPC optimizing the operation of both electrical and thermal renewable energy storage was proposed. A parametrisable mathematical formulation of the optimization problem was presented. Three evolutionary algorithms were tested to solve the optimization problem and a methodology to address physical restrictions was proposed. A genetic algorithm with tournament selection was shown to give the best results. The average daily saving of the MPC compared to a traditional rule-base control was found to be 38.7 %.

As future work, it would be interesting to test the results with variable energy prices, which enable to take even more advantage of the thermal and electrical storage.

Acknowledgments

This work was developed as part of the HAPPENING Project, which has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement No. 957007.

Abstract

Bayesian optimization with surrogate modeling is widely used to calibrate building energy models. However, complexities arise in surrogate modeling due to the variability in building morphology at the urban scale. Thus, maintaining dynamic simulation accuracy is crucial. This study presents a novel optimization framework for calibrating district-building energy models using Bayesian decision theory. Once tested on a case study district, the approach reduces monthly calibration error by approximately 45%. Future works could be employing more robust classifiers and handling imbalanced target variables. The proposed approach can minimize computational demands for optimizing dynamic models while ensuring reliability.

Introduction

Building energy use contributed to 60 million tons of increase in greenhouse gas (GHG) emissions globally in 2022, comprising over 19% of the total rise in GHG emissions from the world's overall energy consumption (OECD, 2023). The construction industry should be investigated thoroughly to understand and reduce such a vast energy use. The occupant-related uncertainties (Santin et al., 2009) and the diversity in the characteristics of the urban building stocks (Oraiopoulos and Howard, 2022) complicate the analysis of the building energy demand with reliable assumptions. Similarly, the construction industry's partial failure in digitization and the resulting lack of comprehensive data hinder studies examining the energy consumption of urban building stocks (Reinhart and Davila, 2016) (Ferrando et al., 2020). However, well-equipped building energy models can provide sustainable solutions to monitor and control urban building energy use (Wang et al., 2018) (Buckley et al., 2021). Dynamic models in building energy modeling (BEM) and urban building energy modeling (UBEM) involve creating computer models that simulate the energy performance of buildings. During simulation, these models evaluate many factors, such as building materials, HVAC systems, occupancy patterns, and weather conditions. Unlike statistical models that analyze the correlation between the building energy-related parameters and the resulting energy consumption and provide predictions usually at lower temporal resolutions (e.g., annual predictions), dynamic models track how energy usage fluctuates throughout the day, week, month, or even year by considering the variations in the building operational schedules and the climate conditions (Pan et al., 2023).

The parameters of dynamic models often need calibration due to insufficient data to characterize buildings accurately, especially at urban level analysis, where diverse building stocks complicate calibration against metered consumption data (Chong et al., 2021). However, calibration is an iterative process that hinders the parametric optimization of dynamic models, which are computationally expensive due to exhaustive simulations covering the thermal interaction between building components. In this sense, Bayesian Optimization stands out as a powerful technique for calibrating simulation parameters (Hou et al., 2021). Traditionally, Bayesian Optimization employs surrogate models, such as regression models or Gaussian processes, to approximate the complex relationships within the dynamic simulation framework (Hou et al., 2021). These surrogate models replace the actual dynamic models and significantly reduce the computational time. They facilitate assessing various scenarios and obtaining optimal parameter combinations efficiently.

For instance, Markov chain Monte Carlo (MCMC) algorithms are prevalent optimization methods that employ surrogate modeling to estimate the posterior distribution of unknown parameters in Bayesian calibration. MCMC algorithms iteratively determine optimization directions by assessing parameter combination errors. In this regard, it resembles the online learning concept adopted in Artificial Neural Network (ANN) models (Rumelhart et al., 1986). Dynamic models are black box models whose simulation output depends on various complex assumptions and factors. Therefore, surrogate modeling approaches are valuable in BEM or UBEM when the dynamic models offer no analytical solution that refers to a direct mathematical method for determining the likelihood of parameter values and, consequently, the posterior probabilities (Hou et al., 2021). Surrogate models are effective when there is little or no knowledge about the possible values of the parameters and their prior probabilities.

However, replacing the dynamic models with surrogate models might yield a loss of accuracy in modeling complex patterns in building morphology at the district and urban scales. When the objective function is spoiled due to the high uncertainty raised by urban building stocks, the optimization process can be faulty. Therefore, the precision of models defining the optimization function becomes crucial even though utilizing an actual model instead of a surrogate model in the likelihood creation process can be exhaustive. Hence, this study proposes a simplified Bayesian optimization method to overcome the limitations arising from the computational requirements and reliability of surrogate modeling. Here, the primary aim is to filter and reduce the size of the parameter space. The proposed approach defines a simplified version of the Bayesian likelihood by assessing the probability of success in scenarios. This approach can be utilized for optimization problems that involve complex computational models (dynamic models) where the actual objective function is not easily accessible. It can be precious when uncertainty regarding the possible value ranges for simulation parameters can be significantly reduced through knowledge acquired from buildings' energy-related records or thorough research. Therefore, it can potentially enhance the optimization process without relying on surrogate modeling techniques.

Methodology

The methodology consists of five sequential steps. First, a dynamic model of the buildings in a selected district is constructed. Next, energy simulations are conducted for various scenarios, each comprising different combinations of simulation parameters, through the dynamic model. These scenarios are then compared with the measured data and labeled as desired and undesirable according to their monthly simulation errors. Subsequently, a Gaussian Naive Bayes Classifier is developed to classify scenarios as either desired or undesired. This classifier enabled the optimal parameter combination to be derived from the posterior distributions of the simulation parameters. Ultimately, a Bayesian Model is created using the optimal parameter combination, and a final energy simulation is performed to evaluate the proposed calibration of the dynamic model. The methodology workflow is demonstrated in Figure 1.

1. Building A Dynamic Model

The proposed calibration approach begins by creating a dynamic energy model for a sample district. Choosing a modeling tool with a user-friendly interface is crucial for easy adjustments to input data to optimize the dynamic model. Furthermore, the performance of the selected modeling tool must be validated, particularly in urban-level building energy assessment, to ensure its robustness and reliability. Therefore, the Urban Modeling Interface (UMI), a widely used tool in urban planning studies worldwide (Ang et al., 2022), is selected to assess the building energy consumption of the sample district. UMI is developed by MIT Sustainable Design Lab (Reinhart et al., 2013). UMI is integrated into a computer-aided design (CAD) program called Rhinoceros 3D (Rhino) that provides a user-friendly environment for the modeling and simulation steps (McNeel and Associates, 2008). UMI requires three main types of input data to create a 3D dynamic model. These are building templates, building geometries, and weather data. A building template is text-based data that includes various categories with the essential characteristics of the buildings, such as the building envelope properties, zone conditioning details, HVAC details, domestic hot water (DHW) details, and building operational schedules. Each category requires a detailed description of the mechanical systems, building parts, or operations. A building template should adequately represent the selected buildings in a district to ensure the accuracy of the energy simulation. Buildings are represented within archetypes of building energy models since modeling each building with its specific characteristics is time-consuming at the district and urban scales. The following input of the dynamic model is the building geometries. Building geometries are attained from existing building footprints or newly created ones in GEOJSON format. These footprints, along with building heights and glazing ratio of building surfaces, are processed in the UBEM.io tool (Ang et al., 2022) to create the building geometries. The final input of the dynamic model is weather data in EnergyPlus Weather (EPW) format. Typical EPW weather data includes comprehensive meteorological information such as temperature, humidity, wind speed and direction, solar radiation, and precipitation recorded at regular intervals. Once these three components of the dynamic model are gathered, the 3D UMI model is ready for the energy simulations.

2. Performing Energy Simulations

The dynamic model consists of various inputs (simulation parameters) that represent the energy consumption characteristics of buildings. These parameters need optimization to minimize simulation errors. Once the simulation parameters are identified for optimization, scenarios are crafted by combining them, and these scenarios are integrated into the 3D UMI Model as building templates. Monthly energy simulations are subsequently conducted for each scenario.

3. Labeling Scenarios

Monthly simulation errors of the scenarios against metered data are calculated using the Coefficient of Variation of the Root Mean Square Error (CV-RMSE) (Equation 1).

$$CV-RMSE = \frac{1}{\bar{r}}\sqrt{\frac{\sum_{t=1}^{N}(r^t-y^t)^2}{N}} \tag{1}$$

In Equation 1, $\bar{r}$ is the average of the monthly target consumption obtained from metered data, r^t represents the monthly cumulative target consumption, y^t is the monthly cumulative simulation result, and N is the total number of monthly simulation outputs, which is twelve. As seen from Equation 1, CV-RMSE decreases as the monthly simulation errors get smaller and more consistent. Hence, it simultaneously evaluates the stability and accuracy of the dynamic model. Additionally, an error metric named MAPE, which calculates the average percentage difference between simulation results and metered data, is utilized to measure the scenario errors (Equation 2).

$$MAPE = \frac{1}{N}\sum_{t=1}^{N}\left|\frac{r^t-y^t}{r^t}\right| \tag{2}$$

The main idea of the proposed approach is to label scenar-

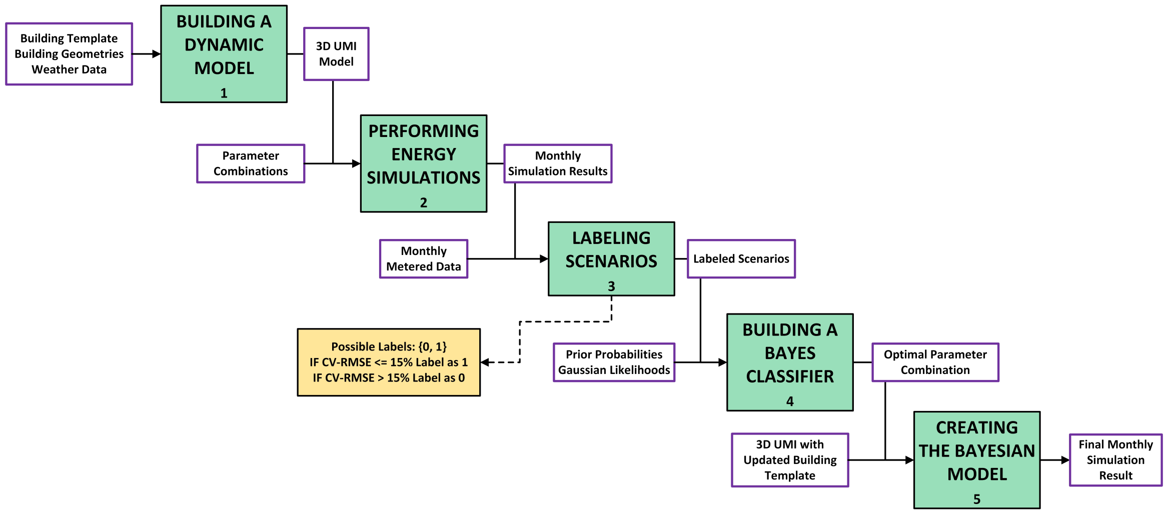

Figure 1: Methodology workflow

ios according to their simulation errors and subsequently perform classification to derive the optimal parameter values. To achieve this, a maximum allowable error limit for CV-RMSE is defined. ASHRAE suggests that the simulation (or prediction) error should not exceed 15% at the monthly resolution based on the evaluation metric CV-RMSE (ASHRAE, 2002). Thus, the maximum allowable error is set to 15% of CV-RMSE, and each scenario is labeled according to the total operational energy use intensity. For example, if a scenario's error is less than or equal to the maximum allowable error, the scenario is labeled one, and zero otherwise. The scenarios with label one are considered as desired scenarios.

4. Building A Bayes Classifier

The optimization becomes a binary classification task after labeling scenarios. Here, the goal is to derive the posterior probability distributions for the scenario labels (zero and one) using the Bayes formula in Equation 3:

$$P(L_i \mid X) = \frac{P(X \mid L_i)P(L_i)}{P(X)} \tag{3}$$

In Equation 3, X denotes the parameter combination, and L_i represents the scenario label. There are two possible labels for each scenario: $L_i = \{0, 1\}$. The posterior distributions for the labels zero and one are determined using the likelihood function $P(x \mid L_i)$ and prior probabilities $P(L_i)$ since the denominator $P(X)$ is the same for both labels. The term $P(X)$ in the denominator is called evidence, which is the probability of observing a certain parameter regardless of a condition. The prior probability $P(L_i)$ is the ratio of the number of scenarios with label i (zero or one) to the total number of scenarios. The likelihood function is the joint probability distribution of the simulation parameter combinations for each label. Here, the simulation parameters are assumed to be conditionally independent for simplicity of the optimization (Equation 4. This transforms the model into a Naive Bayes classifier.

$$P(X \mid L_i) = \prod_{m=1}^{n} P(x_m \mid L_i) \tag{4}$$

The likelihood function is the multiplication of the conditional probability of each simulation parameter over a given label. In Equation Equation 4, m is five since there are five parameters in scenarios. Each conditional probability $P(x_m \mid L_i)$ is assumed to have a Gaussian (normal) distribution with the parameters μ_m (mean) and σ_m (standard deviation) as shown in Equation 5.

$$P(x_m \mid L_i) = \frac{1}{\sigma_m\sqrt{2\pi}} \exp\left(-\frac{(x_m - \mu_m)^2}{2\sigma_m^2}\right) \tag{5}$$

Here, the objective is to find the optimal normal distribution parameters for each conditional probability $P(x_m \mid L_i)$. This is achieved by using the maximum likelihood estimation, wherein the gradient of the likelihood function is taken with respect to the distribution parameters (mean and standard deviation) to derive the optimal distribution parameters. These means and standard deviations are chosen to maximize the likelihood of the observed data given each label. Consequently, there are two posterior distributions with optimal mean and standard deviation corresponding to the labels zero and one. The expected value of a simulation parameter x_m, representing the average outcome expected to occur over many repetitions of the random event, can be calculated from its posterior probability distribution conditioned on a specific label L_i. Therefore, the expected values of the simulation parameters are the means of their posterior distributions based on labels one and zero, Here, it is essential to differentiate between simulation and distribution parameters to avoid confusion. Once the classification over the labeled scenarios using a Gaussian Naive Bayes classifier is implemented, each simulation parameter gets posterior distributions for the labels zero and one. The expected values of the simulation parameters are then derived from the means of these posterior distributions. As the optimal values of the simulation parameters should fall within the desired label distributions, the optimal parameter combination is obtained using the expected values of the distributions conditioned over label one.

5. Creating The Bayesian Model

The optimal values of the simulation parameters are integrated into the 3D UMI Model as an updated building template. This updated model forms the Bayesian model. Subsequently, the Bayesian model is simulated, and the monthly simulation results are compared to metered data to evaluate the optimization performance.

Case Study

The dormitory area of Özyeğin University campus in Istanbul was selected as the sample district. There are six dormitory buildings in this area Figure 2. Two energy audit reports from 2014 and 2020, which contain essential information about the energy performance of the dormitory buildings, were used to identify and characterize buildings in the building template. The dormitory buildings have similar building properties and energy consumption patterns. Therefore, a single archetype, named Dormitory, was created to represent all the buildings in the dynamic model. To create building geometries, polygons representing the building footprints in the district on the map were initially drawn in Yandex Map Constructor. These footprints were then saved as a map layer and exported as a GEOJSON file. Subsequently, this file was processed in the UBEM.io tool, in which a GIS interface ensured that the buildings were located in valid coordinates and that the footprints were not overlapping. Building heights were incorporated into UBEM.io to finalize the geometric model. There are multiple weather stations near campus. The hourly weather data between September 2018 and September 2023 were obtained from the Turkish State Meteorological Service (TSMS) from the nearest station to the campus. This data includes temperature, relative humidity, dew point temperature, wind direction and speed, sun exposure intensity, global solar radiation, and total precipitation at the hourly resolution within the given years. After obtaining three major components of UMI, a dynamic model of the district was established.

The metered data obtained from the campus energy management department includes natural gas and electricity consumption. This data forms the study's validation data. The dynamic model created via UMI considers several end-uses when determining the operational energy consumption of the dormitory buildings. Among these end-uses, cooling, equipment use, and lighting energy are set to be provided with electricity, whereas heating and DHW are supplied by natural gas. The electricity and natural gas consumption are recorded for each building at the monthly resolution. Even if small air conditioners cool the offices of the authorized dormitory personnel, it is assumed that the dormitory buildings do not have a cooling system. The validation data was derived from the average monthly metered consumption data between September 2018 and September 2023. Notably, the time intervals overlapping with the COVID-19 pandemic significantly impacted the energy consumption patterns of the dormitory buildings due to the absence of occupancy. Thus, the period spanning March 2020 to October 2021 was excluded from the weather and validation data.

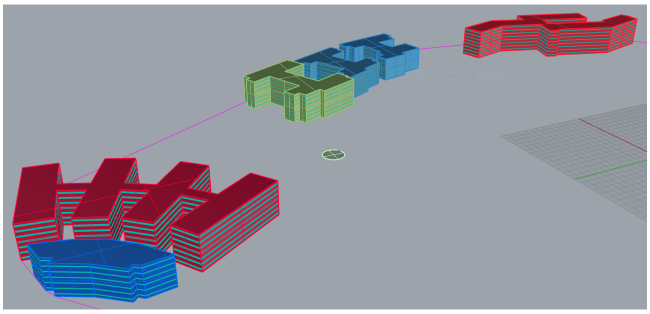

Figure 2: 3D dormitory model in Rhino

The building properties in the energy audit reports were processed, and the average values of the available parameters were used to characterize the archetype in the dynamic model. Table 1 shows the details of the essential parameters of the dynamic model. The dormitory buildings on the campus have similar characteristics. Y1, Y2, Y3, and Y4/5 buildings were built in 2012, whereas Y6 and GH were built in 2019. Hence, there is a small variation in the envelope properties of the dormitory buildings. Some parameters could not be obtained from the energy audit reports, such as infiltration rate, equipment power density (EPD), lighting power density (LPD), and DHW flow rate. There needs to be prior knowledge about the possible value ranges for these parameters. Thus, these parameters were assumed to hold the most uncertainty among the parameter space of the dynamic model and were selected for optimization. In addition, the heating set point was manually selected for optimization since this parameter can drastically affect the intensity of the zone conditioning and the resulting energy consumption.

The unit of the infiltration rate is the air change per hour (ACH), which denotes the ratio of the inside air volume replaced by the outside air due to the natural leakages on the building surface. The air leakage from the building surfaces is expected to be low in the campus buildings since dormitory buildings are constructed after 2012. Therefore, the upper limit of the infiltration rate was set to 0.5, where the minimum was 0.1. Similarly, an upper and lower limits were determined for EPD (Deru et al., 2011) (Mahajan et al., 2017) (Chang and Crawley, 2018), LPD (Deru et al., 2011) (ASHRAE., 2020), and DHW flow rate (Deru et al., 2011) (Murakawa et al., 2005) (Pérez-Lombard et al., 2008) using the literature. Overall, five parameters were chosen for optimization. The average values detected from the literature and the energy audit reports formed the input of the Baseline Model. The possible value ranges for these simulation parameters are outlined in Table 2. Five distinct values were generated for each

Table 1: Simulation parameters of the dynamic model

Parameter Name	Unit	Prior Knowledge
Wall U-Value	$W/m^2/K$	Available
Roof U-Value	$W/m^2/K$	Available
Ground U-Value	$W/m^2/K$	Available
Window U-Value	$W/m^2/K$	Available
Occupant Density	$people/m^2$	Available
Heating and Cooling Set Points	Degree Celsius	Available
Heating COP	%	Available
Infiltration	ACH	Not Available
EPD	W/m^2	Not Available
LPD	W/m^2	Not Available
DHW Flow Rate	$m^3/h/m^2$	Not Available

simulation parameter within the minimum and maximum bounds from Table 2 with equal intervals. This resulted in a total of 3125 parameter combinations. These diverse combinations were simulated in UMI. Monthly simulation errors against the metered data were then calculated using CV-RMSE (Equation 1) and MAPE (Equation 2) metrics. The metered data for monthly natural gas and electricity consumption are available for the dormitory buildings. However, for the sake of simplicity in the calibration process, the total operational energy (TOE) use intensities in kWh/m^2, representing the TOE over the gross floor area of the dormitory buildings, were utilized to compute scenario errors against the metered data. These scenarios were categorized according to their error, with those exhibiting an error smaller than 15% of CV-RMSE labeled as one, and zero otherwise.

Lastly, a simplified Bayesian optimization approach classified these scenarios by employing a Gaussian Naive Bayes classifier. The classifier determined posterior probability distributions for scenario labels based on a likelihood function derived from the simulation parameter combinations. Maximum likelihood estimation determined optimal distribution parameters (mean and standard deviation) for each conditional probability distribution. The expected values of simulation parameters were then obtained from the mean of the posterior distributions. The combination of these simulation parameters formed the Bayesian Model. Subsequently, UMI simulations were performed once more for the Bayesian Model.

Table 2: Optimization ranges for the selected parameters

Parameter	Baseline Value	Min. Value	Max. Value
Infiltration	0.30	0.10	0.50
Heating Set Point	21.50	20.00	23.00
EPD	7.50	5.00	10.00
LPD	6.00	3.00	9.00
DHW Flow Rate	2.55E-04	7.09E-05	7.09E-04

Results and Discussion

The optimal values for the simulation parameter were determined as the means of the posterior distributions for label one (Table 3). The new scenario with the optimal simulation parameters formed the Bayesian Model. A fundamental way to detect the optimal scenario combination is to select the scenario with the least CV-RMSE manually. The manually selected parameter combination with the least CV-RMSE was named the Deterministic Model. According to Table 4, the Deterministic Model decreased the simulation CV-RMSE of the Baseline Model by nearly 60%, whereas the Bayesian Model decreased the baseline error by around 45%. Even though the deterministic calibration seems to provide the optimal parameter combination with the least simulation error, this can be deceptive.

Table 3: Parameter combinations of different models

Parameter	Baseline	Deterministic	Bayesian
DHW Flow Rate	3.90E-04	5.49E-04	6.11E-04
EPD	7.50	5.00	7.41
Heating Set Point	21.50	21.50	20.93
Infiltration	0.30	0.40	0.39
LPD	6.00	3.00	5.77

Let us recall that the simulation parameters were calibrated based on a single target end-use, TOE use intensity. TOE provides an aggregated energy use as it is the summation of electricity and natural gas consumption values. Table 5 and Table 6 demonstrate detailed error comparisons of the calibrated model based on the monthly CV-RMSE and MAPE values. According to Table 5 and Table 6, it is evident that the Bayesian Model achieved a more balanced error distribution between electricity and natural gas. Specifically, the combined average CV-RMSE for electricity and natural gas is 0.267 for the Bayesian Model, compared to 0.318 for the Deterministic Model. This superior performance of the Bayesian Model can be attributed to its detailed parameter combination. As illustrated in Table 3, the simulation parameters of the Bayesian model exhibit distinct values, unlike the predetermined values within optimization ranges provided in Table 2. The likelihoods in the Gaussian Naive Bayes classifier enabled the determination of more precise parameter values. Consequently, these refined values contributed to a more stable and accurate electricity and natural gas consumption simulation at the monthly resolution. Therefore, the proposed Bayesian calibration is more robust than the deterministic calibration.

Table 4: Monthly simulation errors of different models

Model	CV-RMSE	MAPE
Baseline	0.196	0.149
Deterministic	0.080	0.069
Bayesian	0.107	0.101

The efficiency of the proposed Bayesian calibration can be further enhanced when considering the limitations of the Gaussian Naive Bayes classifier. This classifier relies on the naive assumption that simulation parameters are conditionally independent, which may not be entirely true in all cases. The correlation between these parameters can significantly impact the resultant energy consumption. Therefore, modeling the Bayesian likelihood in Equation 4 as a multivariate probability distribution, where the simulation parameters are considered conditionally dependent, could yield more reliable calibration results.

Table 5: Monthly CV-RMSE comparison of the calibrated models based on different end-uses

Model	TOE	Electricity	Natural Gas
Deterministic	0.080	0.478	0.159
Bayesian	0.107	0.277	0.257

The Gaussian Naive Bayes classifier also assumes that simulation parameters follow a Gaussian distribution with a single mean and variance. However, in reality, nonlinear relationships may exist between between the simulation parameters and the resultant energy consumption. Utilizing non-parametric models would enable the detection of these nonlinear patterns in the actual probability distributions of the simulation parameters.

Table 6: Monthly MAPE comparison of the calibrated models based on different end-uses

Model	TOE	Electricity	Natural Gas
Deterministic	0.069	0.466	0.260
Bayesian	0.101	0.156	0.295

Most parameter combinations were considered undesirable scenarios based on their simulation results. Figure 4 shows that almost 90% of the scenarios have more than 15% of CV-RMSE. This caused an imbalanced distribution in the target variable with 2774 zeros and only 351 ones. When the model was trained using these observations, the learning process predominantly focused on the majority class (zeros) rather than the minority class (ones). Therefore, the model tended to classify scenarios as belonging to the majority class. According to Figure 3, the Gaussian Naive Bayes classifier accurately predicted 94% of the zero-labeled, while it only correctly predicted 71% of the one-labeled observations. The imbalanced distribution of the zeros and ones in the target variable induced the classifier to struggle to identify which simulation parameter influences the scenario result and to what extent. Handling such imbalanced data can drastically improve the classification performance and the calibration results.

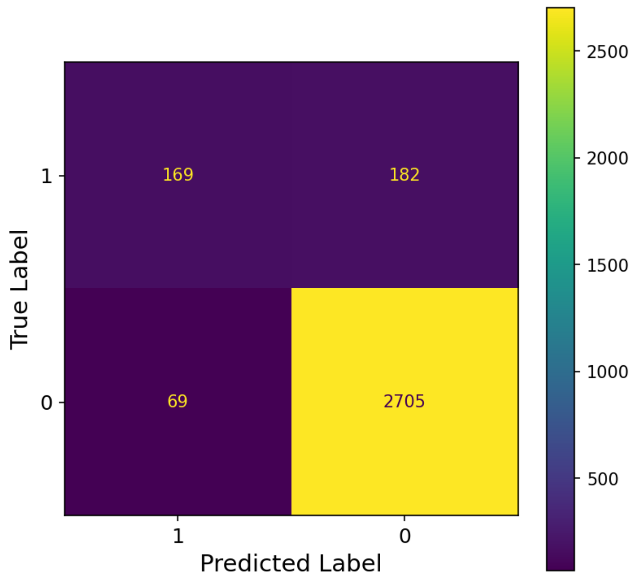

Figure 3: Confusion Matrix for Gaussian Naive Bayes Classifier

Conclusions

Bayesian optimization is widely used to calibrate building energy models. It involves surrogate modeling to reduce computational complexity since the dynamic models

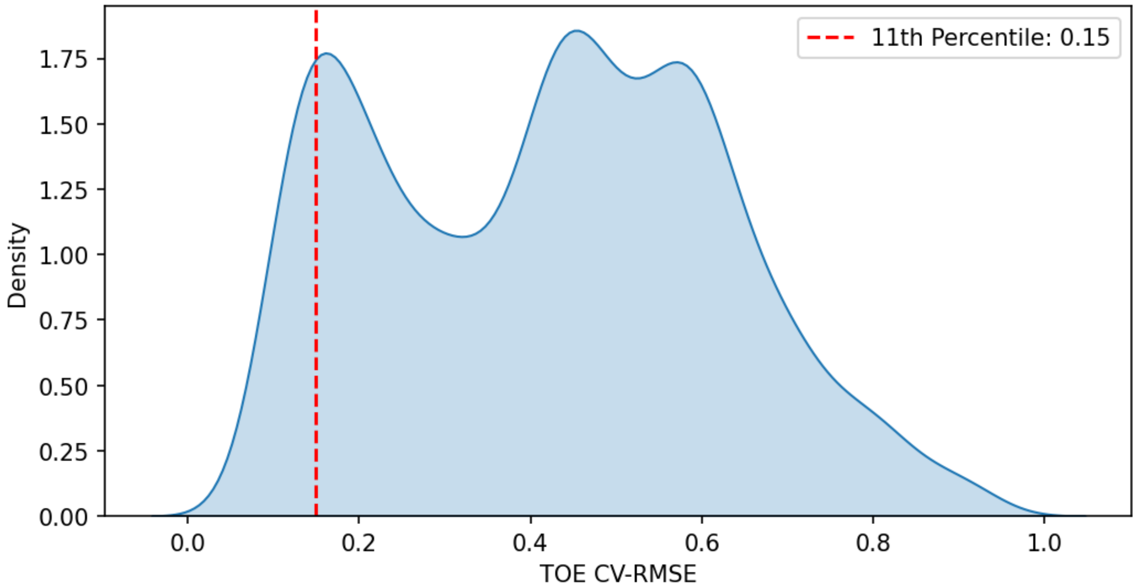

Figure 4: Probability Density Function for the CV-RMSE of the TOE

require extensive simulation time. However, the variability in building morphology and energy consumption patterns complicates surrogate modeling at the urban scale. This study proposes a simplified Bayesian optimization approach to calibrating building energy models at the district and urban scales while retaining dynamic modeling. The proposed approach introduces a novel framework for the parametric optimization of district-building energy models by filtering and reducing the parameter space to enhance the efficiency of the optimization process.

The proposed approach minimizes computational demands for optimizing dynamic models while ensuring reliability by leveraging Bayesian decision theory. Based on the monthly simulation errors, the methodology starts by labeling scenarios with varying combinations of the simulation parameters as either desired or undesired. Subsequently, a binary classifier is employed to categorize these scenarios. To achieve this, the Bayesian likelihoods are modeled as Gaussian probability distribution, with the simulation parameters being conditionally independent. Once the optimal distribution parameters (mean and standard deviation) are determined using the maximum likelihood estimation based on the scenario errors, the expected values of the simulation parameters obtained from the probability distributions constitute the Bayesian Model. This allows for acquiring more detailed and reasonable values of the simulation parameters without the need for exhaustive dynamic simulations. A case study implemented over a dormitory area on a university campus demonstrated the proposed approach's effectiveness. Here, the Bayesian Model significantly reduced the monthly simulation CV-RMSE of TOE for the Baseline Model by around 45% while also delivering balanced and accurate monthly simulation results for the dormitory buildings' electricity and natural gas consumption.

The approach's ability to derive optimal parameter combinations from labeled scenarios offers a practical solution for optimizing dynamic energy models. Urban planners can utilize it to enhance the accuracy of the district building energy models and reduce the energy consumption of the building stocks after testing various energy-efficiency scenarios. A possible future work of this study is to focus on integrating more robust classification models that involve correlations between the simulation parameters and the non-linear patterns in their probability distributions. Another future work can be overcoming the imbalanced label distribution in the target variable to improve the classification performance and the probabilistic calibration. Moreover, classifying scenarios based on natural gas and electricity consumption rather than TOE can help detect seasonal variations in building energy consumption patterns and identify essential parameters affecting seasonal building energy demand.

PASSIVHAUS POST OCCUPANCY EVALUATION AND PROPOSED BIM-BASED INTELLIGENT MODEL

Adam Novogrodskis[1], Zaid Alwan[1], and Bahriye Ilhan Jones[1]
[1] Northumbria University, Newcastle upon Tyne, United Kingdom

Abstract

Passivhaus has been gradually adopted worldwide as the main voluntary building performance standard. While numerous governmental policies and environmental initiatives have promoted the use of low-carbon housing in the UK, the value of Passivhaus has not been fully realised. This paper focuses on UK Passivhaus homes through the perceptions of end-users living in large-scale developments. Case studies are used to obtain feedback on the buildings' performance in the use phase via questionnaire. All surveyed Passivhaus properties were perceived to be very comfortable during the winter, autumn and spring seasons; however, residents were less satisfied with thermal comfort in the summer. This suggests that the standard needs to continuously evolve to address occupant needs. Digital tools can play a role to achieve this. The study concludes a BIM-based process for post occupancy evaluation to overcome heating and thermal discomfort issues.

Introduction

Being responsible for 19% of total greenhouse gas emissions and over 25% of total energy consumption in the UK, decarbonisation of the building sector, especially housing, is crucial in meeting UK's overarching climate targets (UK Housing, 2019). To achieve this, the UK government over past 10 years announced a transition towards zero-carbon buildings and launched the Code for Sustainable Homes policy to assess, certify and promote zero-carbon sustainable design and construction in new buildings (McLeod et al., 2012). However, with the subsequent 'watering-down' of the zero-carbon legislation and eventual withdrawal of the Code for Sustainable Homes in 2015, the UK construction industry has started to debate the validity of the zero-carbon concept as a realistic target (Lynch, 2014). There has been an ongoing debate amongst Architecture Engineering and Construction (AEC) professionals as to how best to address significant carbon reductions, rather than zero- carbon in construction, and whether to deal with materials, fabric, or occupant behaviour. Unlike the net zero-carbon housing policy which primarily focuses on carbon emissions and offsetting by using intensive renewable energy, the Passivhaus standard concentrates on user comfort and conserving energy through a thermally-efficient fabric, passive solar design, airtightness, thermal-bridge-free construction and use of Mechanical Ventilation and Heat Recovery (MVHR).

Several studies have indicated that the Passivhaus standard performs considerably better compared to both conventional and low-carbon housing in the UK (8, 9, 10) and its delivery and adoption in the industry have been limited to approximately 124 units a year, which is 0.07% of 170,000 new-build homes annually constructed in the UK (Ministry of Housing, 2020). Factors suggest that slow Passivhaus standard uptake could be a result of the general private housing sector's reluctance to innovate and adopt energy-efficient home standards (Goodchild and Walshaw, 2011). Concerns with the Passivhaus standard such as its complexity and higher build costs as well as issues regarding excessive insulation, overheating, MVHR and necessary lifestyle changes as a hindrance to its delivery at scale are also factors affecting the adoption (Forde et al., 2020), (Zhao and Carter, 2020), (Pitts, 2017). Hence while there is a public aptitude for low-carbon housing, the construction sector has been not responsive to such needs.

This paper aims to investigate the contemporary drivers of and barriers to delivering the Passivhaus standard in the UK from the user perspective, covering both primary and secondary data. This is achieved through (a) analysing three distinct large-scale residential Passivhaus developments and comparing their occupant experiences, and (b) examining Passivhaus occupants' behavioural patterns and identifying habits/factors that influenced perceived thermal comfort through targeted post occupancy evaluations (POE). The study also proposes a BIM-based intelligent post occupancy evaluation model as a future direction.

Research method

The study adopts quantitative research by conducting a questionnaire through case studies. A total of 174 properties across three different passive house developments are included. Quantitative research in the form of POE was employed as it allowed to gathering of firm, factual data on how the completed Passivhaus buildings were being operated and provided a 'snapshot' of its users' experience and satisfaction at this particular time (Fellows and Liu, 2021). This is vital as the research is trying to identify trends and themes from a variety of cross-comparable accounts (Lucas and Lucas, 2016). POEs have become the preferred industry method to monitor in-use building performance and assess energy performance and air quality as well as collect feedback on thermal comfort, space use, and overall user satisfaction (Meir et al., 2009). The questionnaire was prepared following guidelines from the Post Occupancy Evaluation Toolkit (HEFCE, 2006) as well as specific POE examples (Mlecnik, 2013a). The POE was divided into seven sections including (1) background, (2) occupancy, building type, and use, (3) thermal comfort, (4) energy use, (5) building services and ventilation, (6) air quality and behavioural patterns, and (7) overall impressions. The questionnaire was comprised of 38 questions in total. Most questions were either a checkbox or multiple-choice; however, a 5-point Likert rating scale was also utilized in questions relating to user satisfaction, perceived thermal comfort, air quality, and energy-savings. POEs were collected between September and December 2019 through door-to-door canvassing, postal surveys as well as invited online questionnaires. A total number of 49 POEs were cumulatively collected across the three case studies. Within the scope of this study due to the space limitation, the focus will be on the thermal comfort and behavioural change, living standard improvement and overall satisfaction.

Collected POE questionnaires were then imported into statistical software, Statistical Package for the Social Sciences (SPSS), for further quantitative analysis. Each POE question and the collected answer was correspondingly coded into either a nominal, ordinal or scale variables and analysed to find frequencies, associations and correlations between the answers. Firstly, the analysis was run on nominal demographic variables such as age, gender, tenure, house type, etc. to identify reoccurring occupant and household types, which were then compared to determine if they presented differences regarding comfort, energy savings and satisfaction. The analysis was then conducted on occupants' motivations to live in a Passivhaus property. Lastly, collected data were examined to determine perceived behavioural change, living standard improvement and overall satisfaction with the properties across the case studies. As the majority of collected data was nominal, not normally distributed, and the sample size was fairly limited, non-parametric statistical methods had to be used (George and Mallery, 2019). Therefore, depending on the level of measurement, the collected data were analysed using either a crosstabulation test to determine the association; Mann-Whitney U-test to compare differences between independent groups; or Spearman rank-order correlation to measure the relationship between different variables (George and Mallery, 2019). Particular attention was given to ordinal Likert scale questions asking occupants to rate their satisfaction with a particular aspect of their Passivhaus dwellings such as thermal comfort.

Case studies

Three case studies of the main large-scale residential Passivhaus developments in the UK were conducted to analyse their inception, delivery, and real-life occupancy. The case study methodology was selected for the research as it enabled practical analysis of a broad phenomenon such as Passivhaus standard integration in the UK, which otherwise would have been difficult to examine (Feagin et al., 2016). Investigations by Robert K. Yin highlighted case studies can 'shed empirical light on some theoretical concepts or principles' (Yin, 2009). Just as a laboratory experiment, instead of trying to extrapolate empirical probabilities (statistical generalisation), it allows us to investigate, expand and generalise existing theories (analytical generalisation), e.g., living in a Passivhaus affects occupants' behaviour and perceived comfort (Yin, 2009).

Passivhaus case studies were chosen based on their scale, time of construction, location as well as type of tenure, thus aiming to acquire currently lacking typological data identified by the literature review. The Forgebank project in Lancaster was chosen as a case study because it is currently the only certified Passivhaus cohousing project in the UK, hence providing a unique insight into energy use and behavioural patterns in a highly interactive and social co-housing environment. Racecourse Estate project was chosen because of its specialised design for occupants with mobility needs as well as for having the best co-heating test results among all monitored Passivhaus dwellings in the UK. Finally, the Goldsmith Street project in Norwich was chosen because it is the biggest Passivhaus development in the UK to date as well as the only Passivhaus and social-housing project ever to win the Royal Institute Building Architects (RIBA) Stirling Prize 2019 for excellence in architecture. Besides, all three case studies were chosen so they would differ from each other in terms of their location, size, completion date, and tenure, therefore allowing us to examine the Passivhaus standard under varying conditions.

Case study 1: Forgebank Co-housing

Forgebank Co-housing is a 41-dwelling affordable community housing project in Halton, Lancaster built in 2013. The project comprises a range of house types ranging from flats to two and three-bedroom terraces. 35 of these dwellings are within the co-housing scheme with shared community facilities. All dwellings in the project were designed to Passivhaus, Lifetime Homes and Code for Sustainable Homes level 6 standards (Passivhaus Trust, 2020). At the time of its construction, Forgebank was the second-largest Passivhaus development in the UK and it still is the largest and only Passivhaus cohousing project in the UK. The development went beyond the fabric performance requirements of the Passivhaus standard. It utilised a biomass district heating system, solar thermal network as well a community micro-grid powered by the hydro-electric scheme and photovoltaic panel array mounted on most dwellings' roofs (Lancaster Cohousing, 2020). A review of the building performance evaluation (BPE) revealed that energy-performance aspirations and the Passivhaus methodology were adopted early in the project and Passive House Planning Package (PHPP) software was used to model and test different design options while an airtightness champion was appointed by the contractor to overlook air-barrier installation and air pressure tests (Innovate UK, 2016). Overall, the dwellings were built to a very high standard and performed exceptionally well in co-heating tests, thus practically eliminating the energy performance gap (Lancaster Cohousing Project, 2013).

Case study 2: Racecourse Estate

Racecourse Estate is a 28-bungalow housing development for elderly residents with mobility needs built in 2011 as part of a wider Racecourse Estate regeneration masterplan aiming to replace old housing stock with 4,000 sustainable new dwellings - comprised of 25 terraced (Passivhaus certified and CfSH level 4), and 3 detached bungalows (CfSH level 5) designed specifically for mobility-impaired tenants (Technology Strategy Board, 2014). At the time of its completion in 2011, Racecourse Estate was the largest Passivhaus development in the UK and currently is still the largest Passivhaus development in the North East of England (Passivhaus Trust, 2013). Each house was designed to have an open-plan living and kitchen area, two bedrooms and a mezzanine floor which functioned both as plant roof and loft space, with a total floor area of 66 m2. External walls and roofs were constructed using prefabricated timber cassettes filled with high levels of insulation, while the ground floor was built using a traditional reinforced concrete slab with 300mm insulation and a screed above, with several good areas of practice during construction including careful detailing, fixing damaged areas and use of appropriate gaskets and putty to seal any gaps in service penetrations (Technology Strategy Board, 2014). Moreover, very close collaboration between the project architect and the contractor was observed throughout the project with numerous training events and workshops to ensure on-site construction met raised airtightness and quality targets.

Case study 3: Goldsmith Street

Goldsmith Street is a large social housing scheme built in Norwich city as part of a city council's wider corporate plan to address increasing social housing needs and tackle fuel poverty (Priest, 2019). The development is comprised of 105 units: 45 two-bed terraces and 60 one-bed flats, and arranged in seven terrace blocks laid out east-to-west emulating the Victorian street layout of the adjacent 'Golden Triangle' district (Waite, 2019). In 2019 the Goldsmith Street development was nominated and won the RIBA's Stirling Prize for excellence in architecture becoming both the first Passivhaus and social housing project ever to win such an accolade (Passivhaus Trust, 2019). Moreover, with 105 housing units, Goldsmith Street became the largest Passivhaus scheme in the UK to date (Figure 1).

Figure 1: Goldsmith Passivhaus Development, image by http://www.mikhailriches.com/

Unlike many projects of such scale, the project was delivered through a traditional procurement route which in hindsight allowed the architects to have better control of the build quality, value engineering and retaining the project's initial design aspirations (Waite, 2019). Throughout the project, the design of the buildings took priority: special attention and care were taken to ensure the Passivhaus standard was working for the design rather than the design becoming subservient to make the Passivhaus work (Greengauge, 2020).

Results of Post Occupancy Evaluations

Post-occupancy evaluations were conducted in three different Passivhaus developments varying in their scale, location, typology and ownership (Table 1).

Table 1: House types identified across the case studies

Case	House Type	Construction Type
Forgebank, Halton [Co-housing]	Terrace, End-of-terrace, Flat	Masonry cavity
Racecourse Estate, Houghton-le-Spring [Affordable housing]	Terrace, End-of-terrace, Semi-detached	Timber frame
Goldsmith Street, Norwich [Social housing]	Terrace, End-of-terrace, Flat	Timber frame

Thermal comfort and heating control behaviour

Collected POE data indicated that all surveyed Passivhaus properties were perceived to be very comfortable during the winter, autumn and spring seasons; however, residents were less satisfied with thermal comfort in the summer months. Overall 22% identified they were either less or not pleased with indoor temperatures during the summer season, referring to overheating as the main issue. Concerning heating, SPSS analysis revealed there were some notable differences between the case studies in terms of heating control behaviour and devices used to control indoor temperature.

A comparison of winter heating patterns (Figure 2) highlighted that Goldsmith Street had the most habitual residents. They were likely to have the heating on at a predetermined time of day, i.e. mornings and evenings. In contrast, Forgebank occupants could be considered the most 'reactive'- typically heating their properties only when felt needed. Racecourse Estate residents, on the other hand, were found to be the most energy-conserving, over half of which indicated never needing to have the heating on in their properties.

In terms of heating control and ventilation devices (Fig-

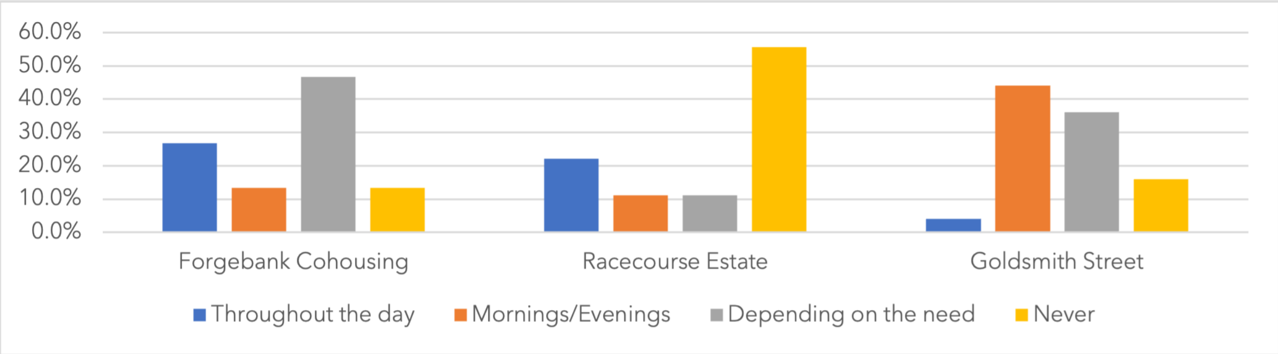

Figure 2: Comparison of winter heating patterns by users across the different case studies

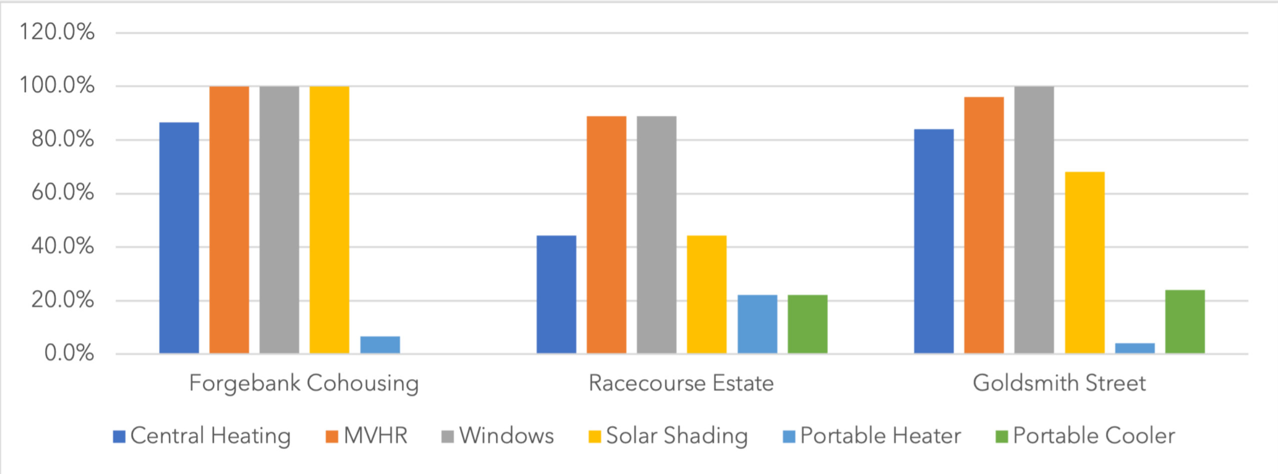

Figure 3: Comparison of winter heating patterns by users across the different case studies

ure 3), collected data indicated that Forgebank and Goldsmith St. residents were still heavily reliant on a conventional central heating system (used by >80% of respondents), in contrast to Racecourse Estate were only 44.4% of end-users reported needing the central heating. That said, Racecourse Estate inhabitants were also found to be the most likely to need a portable cooler to prevent summer overheating, as opposed to Forgebank and Goldsmith St. residents which indicated a much lower need for cooling. All case studies indicated a high use of MVHR and operable windows. Yet, notably, fewer Racecourse residents reported using solar shading, which might explain the summer overheating and need for additional cooling.

Living preferences, lifestyle and overall satisfaction

The last section of the POE research focused on occupants' general perceptions, overall satisfaction and changes to daily lifestyle. Firstly, research participants were asked to identify three main reasons why they chose to live in their Passivhaus property. Radar charts (Figure 4) showed that 'sustainability' was ranked to be the top priority for choosing to live in a Passivhaus across all three case studies (71%). Other top reasons were found to be 'house type'(47%) and 'house price' (43%) while 'community' was ranked as a top priority in the Forgebank development.

Research participants were then asked if living in a Passivhaus has caused a change towards a more sustainable way of life. Collected data revealed that the majority of occupants (41 out of 49) believed living in a Passivhaus has influenced them to adopt a more sustainable lifestyle with 33% of participants reporting a significant change, 49% reporting moderate change and 18% reporting a slight but noticeable change. In terms of overall satisfaction with Passivhaus buildings, collected POE data highlighted that surveyed residents were exceptionally pleased with their homes across all three case studies. Approximately 94% of all participants said they were satisfied or very satisfied with their homes, 6% were neither satisfied nor dissatisfied, and there were no occupants who were dissatisfied with their homes. Furthermore, 65% of residents reported that living in a Passivhaus has significantly improved their living standard, 33% identified a moderate improvement, and 2% found that living in a Passivhaus has not affected their standard of living. In retrospect, 98% of surveyed end-users reported they would recommend it to their friends and family as well as choose to live in a Passivhaus home again if given the opportunity.

Summary of the results

Post-occupancy evaluation data and subsequent SPSS analysis revealed there were significant differences between the case studies in terms of their occupant demo-

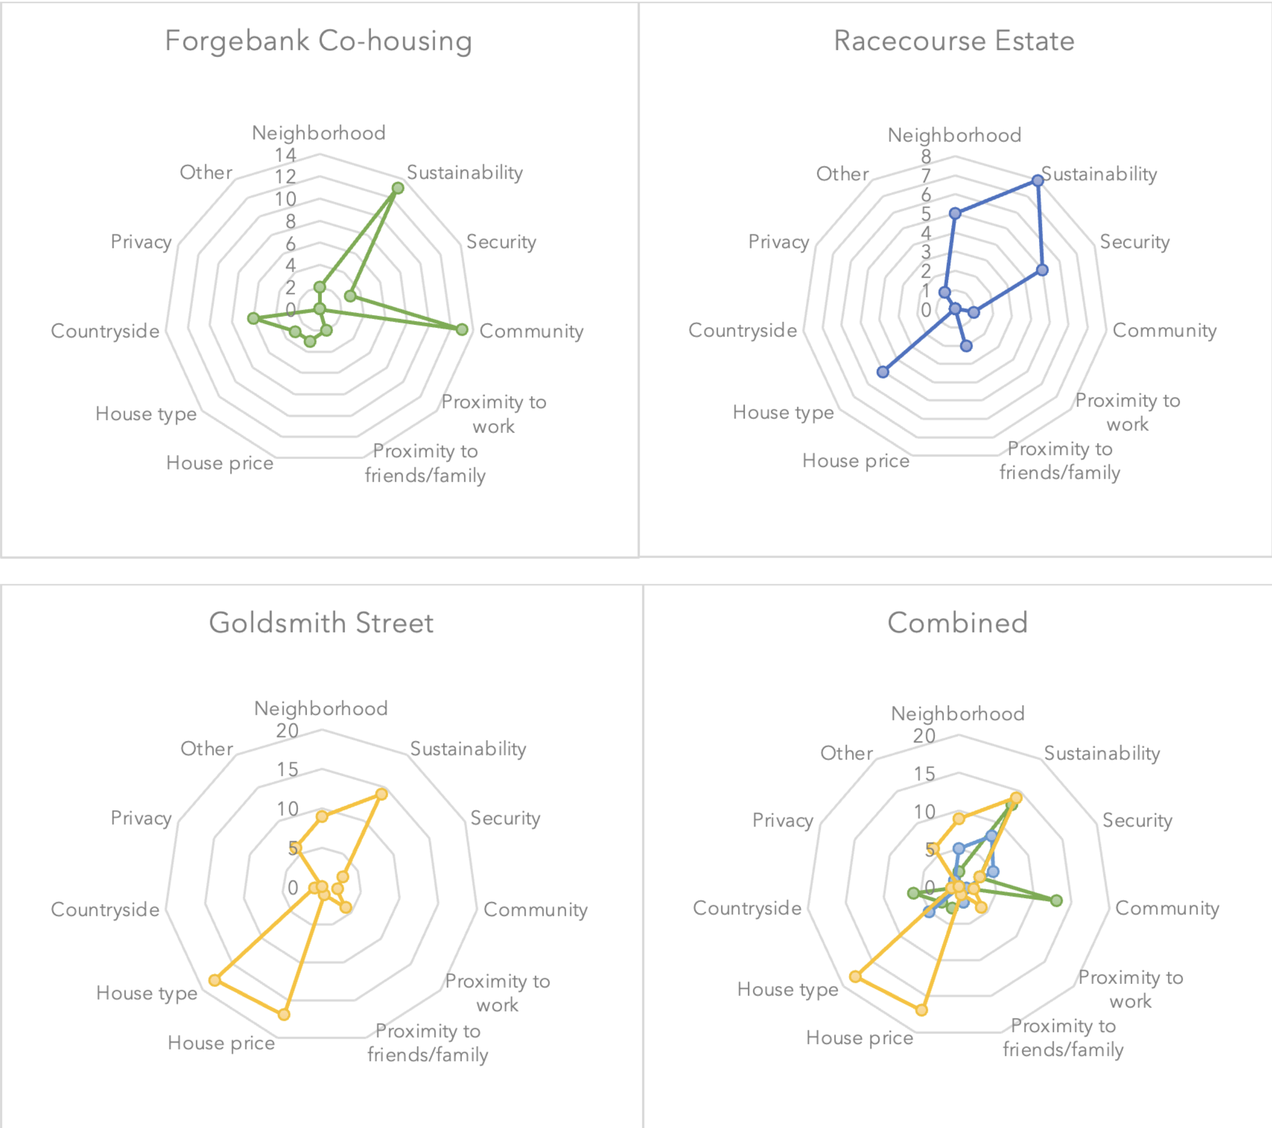

Figure 4: Residents' preferences for Passivhaus elements from the three different case studies

graphics, household types, occupancy and heating patterns as well as heating and cooling strategies. Nonetheless, the SPSS analysis also indicated many commonalities and reoccurring patterns between the case studies regarding thermal comfort and overall satisfaction.

Examined POE data revealed that Passivhaus dwellings across all three case studies were found to be exceptionally comfortable during the winter, autumn and spring seasons. However, all three case studies were also found to have consistently lower thermal satisfaction in the summer months due to reported overheating. Out of the case studies, Racecourse Estate was found to have the lowest summer comfort satisfaction with a mean value of ($\mu = 3.33$). Such results confirm previous study findings on the Racecourse Estate, where substantial overheating was recorded (Siddall et al., 2014), (Fletcher et al., 2017). In terms of overall satisfaction, collected POEs indicated that very high user satisfaction was reported across all three case studies despite significant differences between the Passivhaus properties. The vast majority of residents identified being either satisfied or very satisfied with Passivhaus thermal comfort, energy savings, building services, air quality as well as the overall effect it had on their standard of living.

Such high levels of reported occupant satisfaction confirm previous Passivhaus research findings from both Continental Europe (Cutland, 2012), (Mlecnik, 2013b) as well as the UK (Siddall et al., 2014) where Passivhaus properties were found to be exceptionally comfortable and energy-efficient.

Proposed POE model

Questionnaire results reveal that a more structured POE process is needed to monitor the Passivhaus performance during the occupancy. POE is not structured and not linked to the characteristics of BIM in the design phase. Materials used and the impact of building materials such as conductivity and location etc. are not evaluated during the use

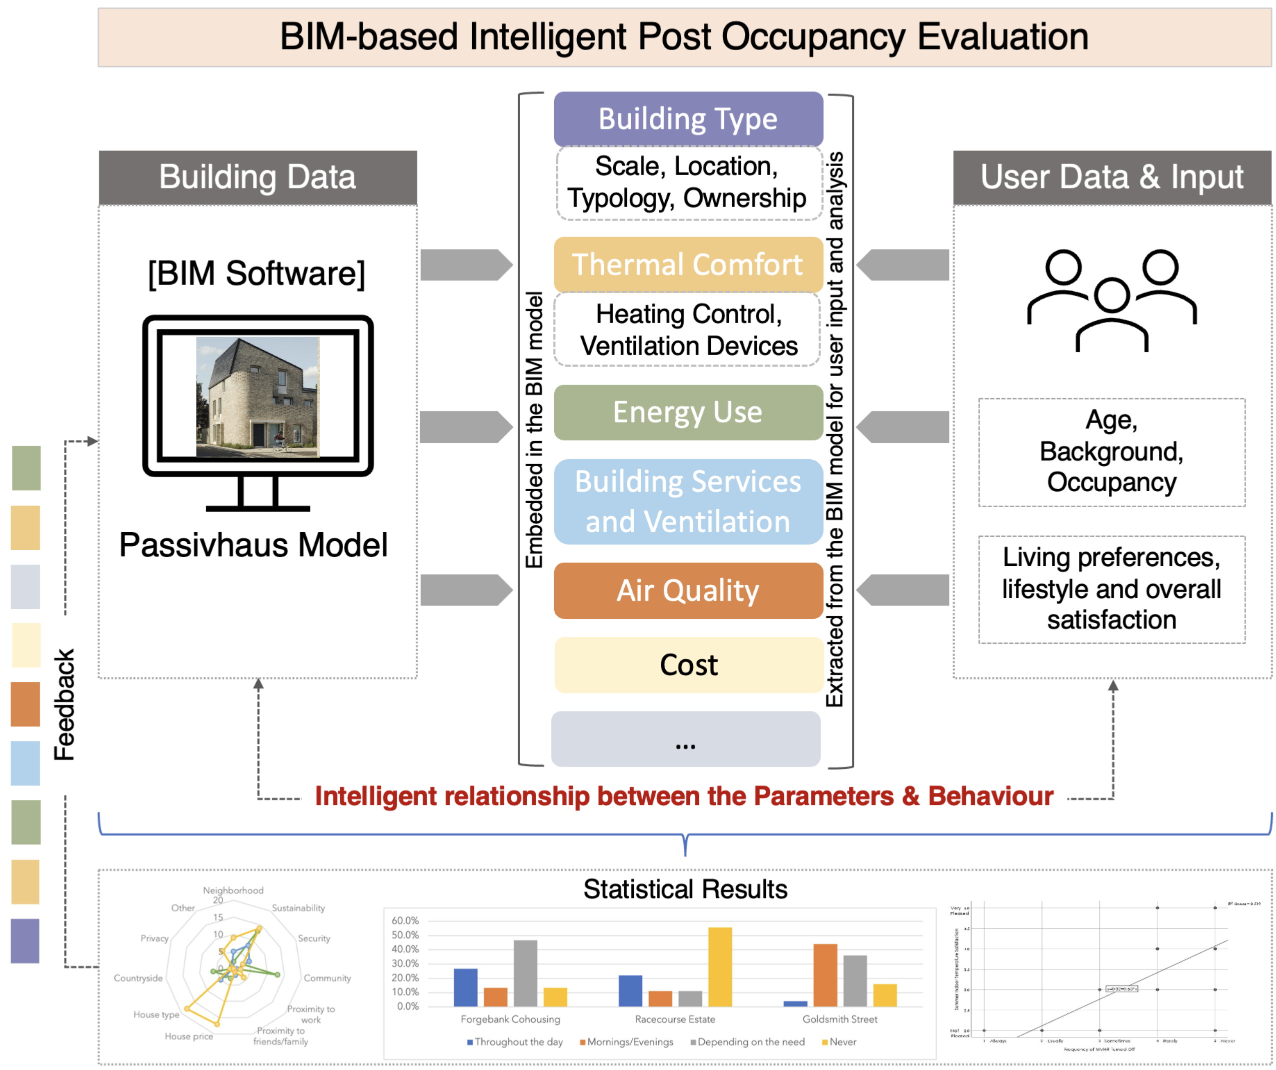

Figure 5: BIM-based intelligent post occupancy evaluation model

phase of the building life cycle.

BIM and other intelligent technologies can help adjust the optimum indoor comfort and energy use as well as identify the related problems based on the actual data for the occupants. Passive houses are very specific and have special features and details, the data should be reflected in the BIM models.

Within the scope of this study, a conceptual attempt was made due to the lack of passive house and BIM data. Enrichment of the BIM model and passive house is possible using the parameters such as building type, thermal comfort, energy use and cost etc. Based on the available data within the BIM model, for example, scale and location can be mapped easily while air quality and energy use cannot be easily integrated until data is available after several years of building occupation. As a baseline, the proposed model is expected to be used enriched for future research and provide solid results. Figure 5 presents a BIM-based intelligent post occupancy evaluation model.

Towards a more digitalised built environment, to facilitate the adoption of Passivehaus, and improvement of design decisions and consequently user satisfaction, automated and smart solutions should be utilised. A prototype sensor visualisation platform can be designed to connect in-use performance data to BIM context data to provide actionable advice for landlords and tenants for minimising repair and maintenance activities. This is mainly because assets do not perform as well as they should when built by comparison to the design phase (Lewry, 2015). Such variations have increased the appetite for carrying out post occupancy evaluation as mentioned in this paper for normally built domestic and commercial assets, however, this is not necessarily the case in the passive house due to the strict air tightness regulations and conditions. This study has revealed that there are still issues associated with important aspects such as the 6 factors mentioned in the model, which are not always integrated with a user-driven feedback process for better building operations for passive buildings. Application programme interfaces (API) could be linked into the system to provide further insight into the conditions that affect housing assets. The measurement of light levels requires further investigation to acknowledge tenant behaviour patterns such as only requiring light at certain times for certain activities (Rogage et al., 2020). In this case, APIs could record simple temperatures, and since the data could be used over time within passive house properties to influence thermal comfort levels, this can prevent issues such as overheating. The data centres could be connected to thermal satisfaction interfaces which could be modified every day depending on the rating given by the occupant on a sliding scale. Thus, over time an optimised model can be developed by feeding this data back into the BIM model specifically designed for asset management of passive houses. Furthermore, the development of artificial intelligence (AI) is a huge potential for programming such processes to take into account occupancy feedback within the building to reduce consumption even more.

Conclusion

This study aimed to analyse the Passivhaus standard in the UK in its present condition through current occupant experiences and discuss the future direction via the proposed POE model. Forty-nine post-occupancy evaluations conducted in three separate case studies across the UK revealed that occupants were generally very pleased with their Passivhaus dwellings. Residents reported high levels of satisfaction with both internal thermal comfort and perceived impact on health. In general, research results were consistent with previous literature findings and the hypothesis that the Passivhaus methodology can deliver highly comfortable homes and substantial energy and carbon savings regardless of the building's location, occupancy or construction. Participants believed that the Passivhaus standard had the potential to evolve to form a foundation for a more robust sustainable housing policy and improvement in understanding occupant behaviour currently lacking in the industry. The findings also highlight there has been a significant lack of longitudinal research and POE of Passivhaus properties over a long period to investigate the longevity of its thermal properties as well as the evolvement of end-user experience. Therefore, up-to-date research investigating the current construction industry's perceptions of the standard as well as revisiting occupant experience in large-scale Passivhaus properties to gain deeper understanding is needed over the long term as we move towards ever more stringent low-carbon targets, through more automated and digital solutions.

A GRAPH BASED FRAMWORK TO SUPPORT DATA-DRIVEN URBAN BUILDING ENERGY SIMULATIONS

Usman Ali[1], Sobia Bano[1], Cathal Hoare[1], Muhammad Haris Shamsi[2], Divyanshu Sood[1] and James O'Donnell[1]

[1]School of Mechanical and Materials Engineering and UCD Energy Institute, UCD, Dublin, Ireland
[2]VITO, Hasselt, Belgium

Abstract

Urban planners and energy policymakers increasingly focus on sustainable urban development and the challenges of analyzing complex urban energy systems. Current models often lack the integration of diverse urban datasets and do not adequately address the dynamic nature of urban energy demands. This study proposes a data-driven framework that involves data collection and preprocessing, building archetypes, machine learning modeling, and parametric simulation. The novel contribution of this research lies in defining the scope, processes, information, data, and relationships for the ontology of urban building energy modeling, employing a graph-based approach for complex data integration. The proposed methodology is tested in residential buildings in Dublin City to examine and compare the modeling results. The study concludes that the proposed model offers a more comprehensive and adaptable approach to urban energy analysis compared to traditional methods. Furthermore, the study helps stakeholders by providing a scalable and flexible modeling framework for urban energy analysis.

Introduction

In the era of rapid urbanization, sustainable development in cities has become a crucial global challenge. The European Union has established a robust legislative framework to enhance sustainable planning and improve the energy performance of buildings. This framework is underpinned by two key directives, the Energy Performance of Buildings Directive EU/2010/31 and the Energy Efficiency Directive EU/2023/1791, both revised in 2023. These directives lead EU member states to adopt policies that aim to achieve a highly energy-efficient and decarbonized building stock by 2050 (EU-Energy, 2023).

Efficient and sustainable urban environments are critical for identifying scalable energy conservation strategies. A promising approach involves analyzing building energy performance data at an urban scale using a data-driven approach. However, the available urban data are often sparse, inconsistent, and lacking in diversity and heterogeneity. Despite these challenges, the last few decades have seen significant advancements in data-driven modeling, particularly in using sparse data to predict and estimate building energy usage. Nevertheless, a gap remains in these studies, primarily due to their focus on prediction and estimation without adequately integrating complex, multidimensional data sets. Therefore, a more comprehensive approach is essential for integrating complex urban building energy dynamics data to improve urban-scale modeling.

Urban planners and energy policymakers increasingly focus on the complexities of urban energy systems, driven by the crucial need to balance environmental sustainability with the growing energy demands of expanding urban populations. However, there is a lack of comprehensive models that effectively integrate diverse urban data sets to analyze urban energy systems. Current approaches often fail to address the dynamic and complex nature of urban energy demands. There is a growing recognition of the gap in the literature, where traditional models are insufficient to capture multifaceted interactions within urban environments. This gap necessitates a novel approach that can holistically encapsulate the intricate energy dynamics of cities.

This study introduces an innovative data-driven framework for urban building energy modeling, taking advantage of ontology and graph-based approaches. The ontology provides a structured representation of domain knowledge, allowing a clearer definition of concepts, attributes, and relationships (Poveda-Villalón et al., 2022; Curry et al., 2013; Hoare et al., 2022). Combining the ontology with a graph database enables creating of a comprehensive knowledge representation system that can efficiently handle diverse and interconnected data, promoting a more holistic understanding of urban energy systems.

Ontology and graph-based techniques are widely used in the field of Building Information Modeling (BIM), linked building data, urban planning, and energy management (Pritoni et al., 2021; Terkaj et al., 2017; Costin and Pauwels, 2022; Li et al., 2019). Kapsalis et al. (2022) use a graph analysis approach to efficiently query and analyze energy efficiency certificates. Wu et al. (2021) propose an ontology modeling solution for managing decentralized data for household energy systems. Van Dam and Keirstead (2010) initialize a model of an urban energy system built on an ontology using energy transformation. Wu et al. (2022) propose an ontology-based framework that can integrate data to build energy simulations from different data sources in the Operation Phase. Baumgärtel et al. (2014) used an ontology framework to assess the application of building performance regulations in design and operation. Daneshfar et al. (2022) proposed an ontology to represent geospatial data to support building renovation to collect data in IFC and CityGML format. Zadeh et al. (2019) developed a hybrid information infrastructure by integrating building design data in ifcXML format and 3D neighborhood models in CityGML format. Shi et al.

(2023) proposed a methodology based on ontology to create a digital twin city information model by integrating BIM, GIS, and IoT technologies. However, existing studies focus mainly on urban building energy management and building information modeling, but more research is needed in the field of urban building energy modeling. Furthermore, available urban building energy models typically do not emphasize data integration, flexibility, scalability, and performance, which are critical to adapting and managing the complexities of urban energy systems.

The novelty of this research lies in defining the scope, processes, information, data, and relationships for an urban building energy modeling ontology. The application of such an ontology uses a graph-based approach to assimilate and analyze complex urban energy data, enabling a more holistic understanding of urban energy dynamics. Furthermore, the framework enriches the predicted machine learning-based data of complex energy modelling scenarios, an aspect rarely explored in existing studies. This integration allows integration of diverse datasets, ranging from building stock to energy consumption patterns, and fosters a deeper understanding of the interdependent factors that influence urban energy systems. This study aims to offer a more comprehensive and adaptable approach to urban energy analysis, surpassing the limitations of traditional methods.

The article is organized as follows: Section 2 provides a detailed discussion of the methodology devised for urban energy modeling of residential buildings. Section 3 discusses the case study of Irish building stock. Finally, conclusions are discussed in Section 4.

Methodology

Modeling the energy performance of buildings on a large urban scale presents a formidable challenge for urban planners and policymakers. Accurate prediction of energy consumption and identification of energy efficiency opportunities are essential to promote the sustainable development of cities.

Therefore, this study proposes a framework for modeling the energy performance of buildings on an urban scale, which begins with the development of an ontology and its implementation in a graph database. This lays the foundational framework for representing and analyzing the complex interrelations of urban energy performance (Figure 1). The process involves comprehensive data collection and preprocessing to gather and refine building-related data. Subsequently, building archetypes are developed to define representative models of buildings, capturing the diversity of the urban built environment. These archetypes serve as the basis for parametric simulations, exploring the energy performance under various scenarios and conditions and generating a synthetic dataset for analysis. Machine learning models are then employed to predict energy performance across the urban scale, leveraging the insights gained from synthetic and real-world data to identify opportunities for energy efficiency improvements. Finally, this structured approach facilitates querying and data analysis, providing a detailed understanding of urban building energy performance. This holistic approach integrates sophisticated data analysis and modeling techniques to offer actionable insights for promoting sustainable urban development.

Urban Building Energy Modeling Processes

The proposed ontology for urban building energy modeling includes building archetypes and parametric simulation data, which are used to generate synthetic data (Figure 3). Ontology also incorporates machine learning modeling results, focusing on predicting the energy performance of buildings based on their respective archetypes. The proposed ontology includes entities such as *BuildingArchetypes, BuildingParameters, ConstructionTemplates, EnergyUsage, and MLPredictedEnergyPerformance*. As a result, this interconnected data enrichment creates a robust platform for urban modeling. This improves understanding of the energy dynamics of urban buildings and enables the development of targeted strategies to improve energy efficiency. The proposed ontology mapping on desired scenarios requires data collection and preprocessing, archetype development, parametric simulation, and machine learning modeling processes. These processes are designed to map complex urban data and scenarios from existing buildings onto ontologies and predict building energy performance.

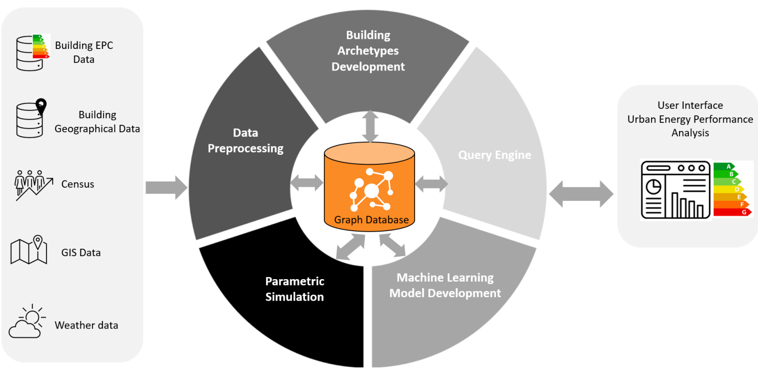

Figure 1: Methodology for data-driven graph-based urban building energy modeling

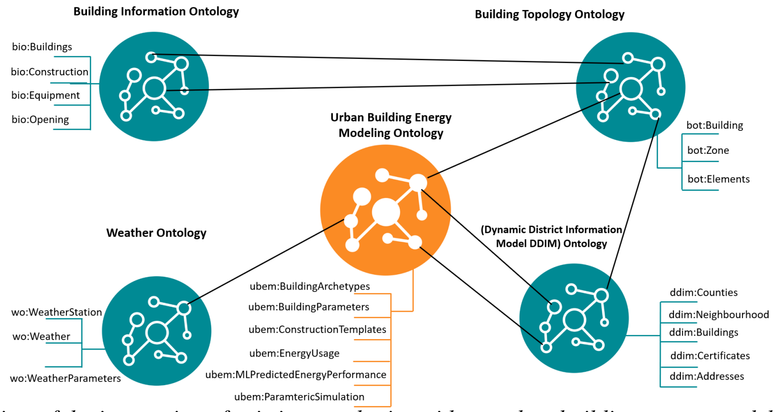

Figure 2: A conceptual view of the integration of existing ontologies with an urban building energy modeling ontology with required entities

Graph Database Development

A graph database is developed to efficiently manage and store complex interconnected data. This database enables the representation of relationships between various data points, such as the link between building types and energy usage patterns, facilitating more detailed analysis and insights (Curry et al., 2013; Zhu et al., 2022). The commonly used graph databases are Neo4j, Amazon Neptune, and OrientDB. A graphical representation of the complex graph model can be presented using the ontology (Hoare et al., 2022).

Ontology refers to a structured representation of knowledge that defines concepts, relationships, and properties within a specific domain, such as urban energy systems (Costin and Pauwels, 2022). These ontologies are represented using the Web Ontology Language (OWL). The proposed ontology for urban building energy modeling has been developed by integrating existing ontologies into the building domain, such as the Building Information Ontology, Building Topology Ontology, Weather Ontology, and Dynamic District Information Model Ontology (Figure 2). Building Information Ontology (BIO) provides a range of defined classes, axioms, and data types for reuse, including Building, BuildingElement, and BuildingParameter (TUWien, 2024a). Building Topology Ontology (BOT) is a minimal ontology to describe the core topological concepts of a building (Rasmussen et al., 2021). To represent weather-related information for a location, the specific Weather Ontology (WO) provides reusable patterns and terms (TUWien, 2024b). The Dynamic District Information Model (DDIM) offers a national-scale digital twin for domestic building stock, complete with geographic information (Hoare et al., 2022).

Data Collection

The ontology creation step starts with collecting available raw homogeneous data sources, including building energy performance certificate (EPC) data, geographic data, census information, GIS, and weather data. These data are gathered from various sources, including national databases and urban planning departments. The data are carefully selected to ensure relevance and accuracy for urban energy modeling.

Data Preprocessing

Once collected, the data undergo a rigorous pre-processing phase. This process involves cleaning the data and handling missing values to ensure consistency. Pre-processing also includes categorizing buildings based on characteristics such as age, region, and type of usage, which is crucial for developing accurate building archetypes. The preprocessed data are mapped to existing BIO, BOT, DDIM, and WO, further supporting the urban building energy ontology.

Building Archetypes Development

Building archetypes are developed to represent different categories of buildings with similar characteristics within the urban scale. Each building archetype serves as a core entity (*ubem:BuildingArchetypes*) for graph-based integration of urban buildings and requires specified features, such as geometry, layout, construction materials, insulation levels, and typical energy use patterns. These data can be extracted from existing ontologies, namely the BOT and the BIO. Similarly, the DDIM ontology provides all the geographical information for the building archetype. These archetypes serve as foundational elements for a parametric simulation framework that models energy performance in various types of buildings. In addition, these archetypes are essential for urban modeling because they encapsulate common building characteristics that can be used to generalize energy performance assessments.

Parameters Simulation

Parametric simulation generates synthetic data to simulate various energy consumption and performance scenarios to find the optimal solution, especially when a sparse data set is available for energy modeling (Ali et al., 2024). Parametric simulation uses developed archetypes and also sources data from the weather ontology for simulation. It stores all input and output results in a graph-based structure using building parameters (*ubem:BuildingParameters*), Construction (*ubem:ConstructionTem-*

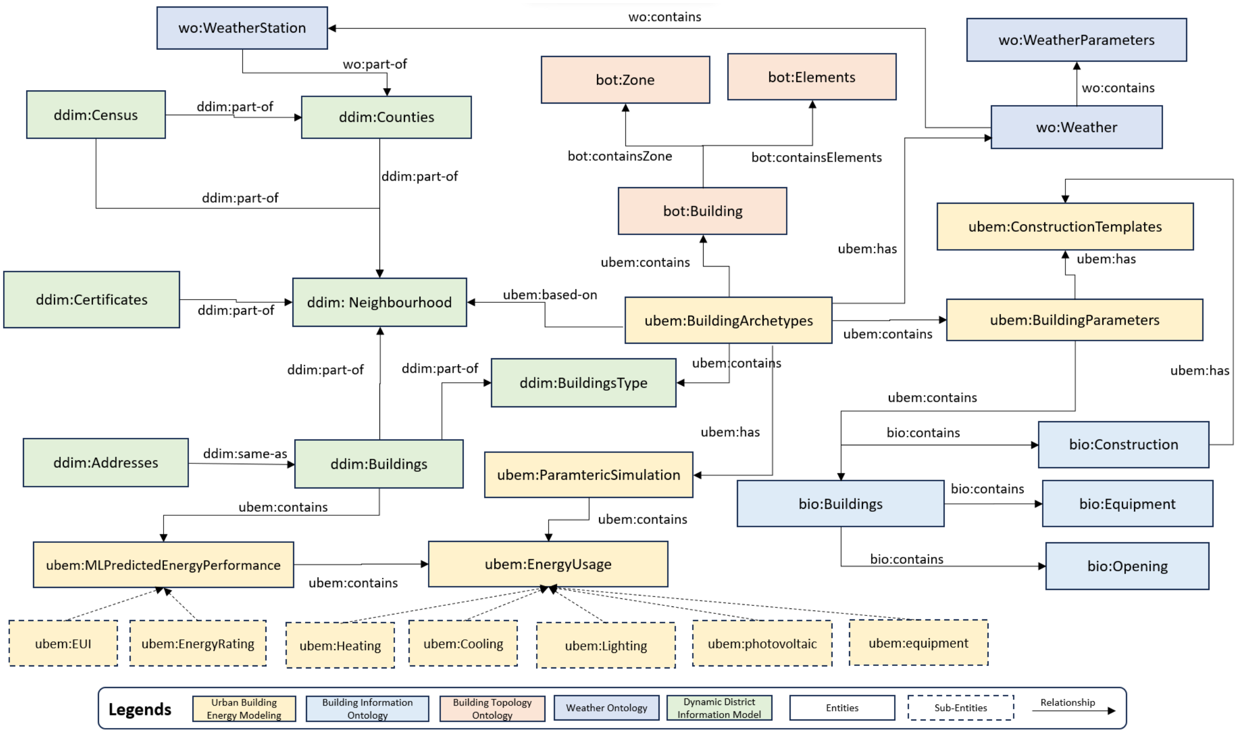

Figure 3: Graph structure for urban building energy modeling for residential building stock

plates), and the energy usage (*ubem:EnergyUsage*) entity. (*ubem:ParamtericSimulation*) entity estimates are determined using thermal modeling to assess heating, lighting, and water demands, and employing an energy simulation engine to evaluate the overall energy performance of the building under different conditions. A parametric tool performs numerous simulations using a simulation model (Ali et al., 2024) to perform complex parametric simulations involving multiple parameters. In this paper, JEPlus serves as a parametric tool for energy simulations. Additionally, JEPlus uses EnergyPlus for simulations, integrating various parameter values together with weather data and construction templates. However, due to the complex nature of the numerous parameters involved, generating simulated data for all parameters becomes nearly impossible. Therefore, synthetic data are generated using sampling methods such as Simple Random Sampling (SRS) and Latin Hypercube Sampling (LHS). These methods help generate the desired sample data that includes combinations of all parameters. Parametrically simulated data produce synthetic data sets stored back in the graph database and then used as input for developing machine learning models.

Machine Learning Modeling

Data-driven Machine-Learning (ML) models have been designed to enrich the predicted results for urban energy use scenarios in graph databases. The workflow involves formulating regression ML models to store predicted results in the energy performance entity of the building, specifically in terms of Energy Use Intensity (EUI) and energy rating. The model is trained using the data stored in the graph database. Generally, the models developed include the process of splitting data into training and testing sets, followed by the application of regression algorithms based on performance indices (Ali et al., 2024). These models are continuously refined to improve accuracy and adaptability to evolving urban dynamics. Furthermore, the models predict the intricate characteristics of buildings on an urban scale and store these predicted data in a graph database using *ubem:MLPredictedEnergyPerformance* entity for further analysis. The enrichment of ML-based building energy performance in graph-based databases offers dynamic, context-aware insights, significantly enhancing the precision and relevance of urban building energy modeling.

Query Engine

Developing a query engine enables efficient retrieval and data analysis from the graph database developed based on the proposed ontology. This engine supports complex queries, allowing users to extract specific insights, such as determining the influence of particular building characteristics on energy consumption or identifying potential areas for energy efficiency improvements. The most common graph database query languages are Cypher, GraphQL, and SPARQL (Kapsalis et al., 2022; Zhu et al., 2022; Hoare et al., 2022). Cypher is one of the most widely used query languages for graph databases, especially in the context of Neo4j. GraphQL is a query language primarily designed for APIs, but it can also be employed to query data from graph databases. On the other hand, SPARQL is a query language specifically used for querying RDF (Resource Description Framework) data. The proposed ontology, coupled with graph-based integration for urban

Table 1: Data requirements and associated data sources for Dublin graph-based database

Ontology	Prefix	Irish Data Source	Publisher

building energy modeling, can be further examined using a query engine based on data integration, flexibility, scalability, and performance. This study examines the query engine with and without machine learning-based data enrichment for estimating urban building energy performance.

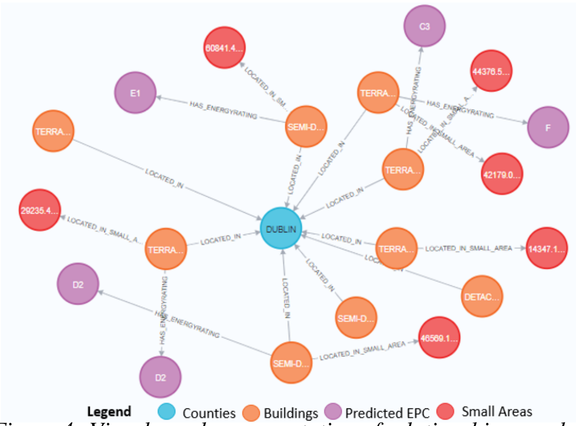

Figure 4: Visual graph representation of relationship complex urban building energy modeling for Dublin city

Urban Energy Performance Analysis

Finally, the methodology culminates in a comprehensive analysis of urban energy performance. This involves using the models and tools developed to evaluate and interpret buildings' energy efficiency and the overall energy dynamics of the urban area. Graphical or GIS-based modeling results can be integrated into the analysis using data stored in the DDIM ontology for geographical information. The analysis provides valuable information on current performance levels and identifies opportunities for optimization and improvement.

The study aims to provide a robust and comprehensive framework for urban building energy modeling, providing a deeper understanding of urban energy dynamics and paving the way for more sustainable urban development.

Case Study

The primary objective of this case study is to test the proposed methodology on the residential building stock of Dublin, Ireland. This study demonstrates the effectiveness of an ontology-driven approach in the management and analysis of complex urban building data. The application of this data-driven framework to buildings in Dublin has revealed significant insights into the dynamics of urban energy. Adopting an ontology-driven methodology supported by Neo4j graph database technology transforms the management and analysis of Dublin's residential building stock. Furthermore, this study helps in detail urban energy insights through a more structured, interconnected, and efficient data framework than conventional approaches.

Irish Graph Database Development

This study uses a Neo4j graph database to implement the proposed urban building energy modeling ontology. Neo4j efficiently stores nodes and relationships, significantly streamlining complex data management. Using Neo4j's capabilities, the study effectively represents and interlinks various urban data. The interconnected data enables comprehensive analysis of urban energy, facilitating the identification of patterns and insights that are difficult to identify with traditional methods due to complex relationships and interdependencies at an urban scale. The graph-based structure of Neo4j also allows high-performance querying and data retrieval, making it an ideal platform for handling complex queries essential for comprehensive urban energy modeling and analysis.

Gathering data on an urban scale for a building stock is a challenging task, as individual building information is often limited and sparse. The data collection process for this study involved acquiring raw building data from multiple sources to map them to the proposed or existing ontology. The case study includes data such as building energy performance certificates, building geographical data, census information, GIS, and weather data (Table 1).

In Ireland, the data set for EPC (also known as the Building Energy Rating (BER) certificate) of Irish residential stock represents a comprehensive measurement of the building stock, which includes more than 200 characteristics of the buildings. These characteristics include the building fabric, heating systems, estimated end use, CO_2 emissions, and estimated delivered and primary energy consumption. The Irish EPC dataset contained approximately 1.1 million residential buildings, with a substantial number of building ratings that fall within the C1 to D2 range (SEAI, 2023). EPC data assists in retrieving building-related data for archetype development, based on building topology and building information ontology requirements.

The Irish census provides spatial data on various scales and the number of buildings in each geographic area, such as small areas (neighborhoods), and counties (CSO, 2022). Furthermore, the GeoDirectory database, updated by An

Post (Irish Postal Service) and Ordnance Survey Ireland, offers statistical and geographical information on the entire Irish building stock. The Q2 2023 GeoDirectory report includes geocoded addresses of 2.1 million residential buildings (GeoDirectory, 2023; OSI, 2023). This study focuses on Dublin City, and the EPC data is available only for about 54% of the residential building stock in Dublin City. GeoDirectory is a useful resource for urban energy modeling and is required for the DDIM Ontology to analyze geographical aspects of modeling results. Furthermore, Dublin weather data is used to evaluate the impact of weather conditions on energy performance based on weather ontology requirements. This study integrates sparse and heterogeneous urban building data using a graph-based approach. Then, machine learning algorithms are applied to this integrated data set to predict the energy rating of the remaining 46% building stock.

After the initial data collection process, all data undergo a rigorous preprocessing phase. This phase involves cleaning the data and addressing missing values to ensure consistency. The preprocessed data mapped to the ontology are then used to create a Neo4j graph-based database. This step is crucial as it involves removing all irrelevant data and including only relevant data, which is essential to improve the performance of the query engine and the execution of complex queries for urban-scale modeling. For example, the Irish EPC database contains more than 200 features, and this process selects important features for building energy modeling based on existing studies (Ali et al., 2024).

This study uses parametrically simulated data comprising 1 million entries, generated using four residential archetypes such as semi-detached, detached, terraced, and bungalow. These archetypes were developed using available Irish building data based on data requirements of BIO, BOT, and DIMM ontologies. These parametric simulated data are created using DesignBuilder construction templates for building parameter mapping. Parametric data are stored in Neo4j and are further used for data-driven machine-learning modeling to predict the energy performance of urban buildings. Neo4j's graph database structure allows for the seamless integration of diverse Dublin data sources, providing a more comprehensive view of urban energy systems compared to traditional data approaches. Neo4j can help improve the generation of models for energy performance for urban buildings due to the richness of data and relationships available in the graph. The data are then partitioned into two subsets to create training and testing datasets, employing a cross-validation algorithm. These data sets were trained and evaluated using regression models (eXtreme Gradient Boosting) proposed in the existing study (Ali et al., 2024). Finally, the machine learning-based enrichment results are compared with those of traditional simple queries for building analysis.

```
MATCH (b:Buildings)-[:part-of]->(sa:SmallAreas),
    (b)-[:part-of]->(c:Counties {COUNTY: 'DUBLIN'})
WHERE b.BER_ENERGY_MEDIAN > 300
RETURN sa, collect(b) as Buildings
```

Figure 5: A complex query that finds buildings in small areas within Dublin County with an energy performance greater than 300 kWh/m²/yr EUI.

Dublin Energy Performance Analysis

The results show that the Neo4j graph-based database efficiently manages and stores complex data using the proposed ontology for Dublin, demonstrating its interoperability in combining various formats, including spatial and building energy data. The database stores data, including parametric simulated pre-processed data and predicted energy performance data for buildings based on their respective archetypes in Dublin (Figure 4). These interconnected data sets establish a robust foundation for urban modeling, deepening our understanding of the energy dynamics within urban buildings. Furthermore, the graph-based database developed for Dublin buildings exhibits sufficient scalability and flexibility, making it suitable for handling large and complex datasets. This accommodates the ever-evolving nature of urban energy systems and supports various urban planning scenarios.

The Cypher query offers a valuable tool for urban studies, specifically in the context of energy consumption within building infrastructures. For instance, the Cypher query helps to analyze energy efficiency within Dublin County's building infrastructure by identifying buildings with high energy use intensity, specifically those with a median energy performance above 300 kWh/m²/yr EUI (Figure 5). Similarly, the Cypher query can help with urban energy modeling in Neo4j, which is a vital tool input for the simulation of building energy performance within an urban context (Figure 6). The query gets the building parameters from BuildingParameter nodes and inputs them to Simulation nodes. With these parameters, the query sets the stage for parametric simulations that calculate energy performance metrics such as Energy Use Intensity (EUI), heating, lighting, and water usage. This process enables the detailed examination of building performances and facilitates a broader analysis of urban energy consumption patterns. The ability to dynamically adjust and simulate various building parameters provides a data-driven approach for stakeholders.

The developed graph can also help with the breakdown of buildings according to their Energy Rating from "A1" to "G." (Figure 7) The results showed a diverse range of energy efficiencies among the buildings, with the count of buildings for each energy rating varying significantly. The highest number of buildings fell into the "C2" rating, with 24,539 buildings indicating moderate energy efficiency. In contrast, the "A1" rating has the fewest buildings, with only 1,380, signifying the highest energy efficiency. Other notable findings include many buildings in the "D1" and "C3" ratings, with 24,307 and 23,252 buildings, respectively. This distribution highlights the poor energy efficiency in buildings across Dublin, providing insights into the current state of energy performance and potential areas for improvement in building energy standards.

```

```

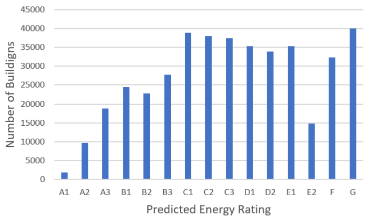

Figure 7: A cyhper query show the distribution of predicted building energy ratings in Dublin

Finally, the developed graph database allows stakeholders to formulate targeted strategies to improve energy efficiency in Dublin, including existing and predicted data, for use in future analysis. Cypher graph queries are used to analyze data within the database, enabling complex analysis. The results can be visualized on a GIS map, highlighting buildings with poor energy performance in a specific Dublin county area, based on Cypher graph queries (Figure 8). This visualization helps decision-makers identify key areas for energy efficiency improvements and informs policy decisions to promote sustainability and reduce energy consumption in the region. Moreover, the flexibility of the database in handling various data formats, including spatial and building energy data, enhances its utility for comprehensive urban planning and energy management initiatives.

Conclusions

This study underscores the growing importance of sustainable urban development and the need for an advanced framework to analyze complex spare urban energy data. The motivation behind this research was to address the

Figure 8: Visual map of buildings with poor energy performance in a specific Dublin county area based on cypher graph query

limitations of current models, which often need help integrating diverse urban data sets and addressing the dynamic nature of urban energy demands.

The key contributions of this research lie in developing a novel data-driven framework. This framework, which encompasses data collection, preprocessing, building archetypes, parametric simulation, and machine learning modeling, leads to the creation of a graph database with ontology and query engine. This approach enables a more holistic understanding of urban energy dynamics while accommodating diverse datasets. An ontology for urban building energy modeling facilitates the integration of complex urban energy data, ultimately offering a more comprehensive and adaptable approach to urban energy analysis compared to traditional methods. This study empowers various stakeholders to analyze and predict complex energy scenarios, thus supporting the creation of more sustainable and energy-efficient urban environments.

The application of the proposed framework could be expanded to include commercial buildings and energy suppliers to assess its applicability and effectiveness in diverse contexts. In general, this research lays the foundation for future advancements in sustainable urban development and energy policy, offering a promising direction for further exploration and innovation in this critical area.

Abstract

The climate change represents an opportunity to revolutionize the urban planning paradigms, turning the role of the cities from massive producers of carbon emissions and pollution into a more sustainable built environment through the exploitation of renewable energy sources. In this transition solar energy plays a key role. In this regard, the novel contribution of this work is twofold: i) providing an interoperability approach for a preliminary version of the solar cadaster for the municipality of Trondheim (Norway), located at high latitude; ii) exploiting the use of the solar cadaster to identify the most usable rooftop areas for solar systems' installations and as supportive instrument for public and private stakeholders to facilitate decision-making for urban energy planning.

Introduction

The revolution of the urban planning paradigms emerges as one of the challenges posed by the climate change. Cities, recognized as significant contributors to carbon emissions and pollutants, should evolve into more sustainable environments. In the energy field, this leads to active engagement by policymakers in exploring the urban potential for energy generation from renewable energy sources (RES). Reducing dependency on fossil fuels by optimizing the utilization of RES enables municipalities to mitigate the carbon footprint associated with their energy consumption (Chatzigeorgiou & Martinopoulos, 2023). Advanced and innovative technology solutions for RES exploitation contribute to this aim. In that regard, comprehensive and interactive urban energy planning platforms can facilitate the implementation of similar strategies within the built environment (Desthieux & Thebault, 2024). In fact, such platforms are designed to empower private and public stakeholders with the necessary insights for informed and timely decision-making. Particularly, instruments for urban energy planning which focus on solar energy potential (i.e., solar cadasters) can boost the adoption of active solar systems, either applied or integrated into the building envelope (i.e., roofs and facades) (Manni et al., 2023). Solar cadasters facilitate users in quantifying the solar irradiation impinging on urban surfaces (i.e., roofs, facades, and ground), enabling them to identify the most suitable areas for the installation of solar systems. However, integrating such instruments into the territorial database requires addressing issues related to interoperability of software performing specific tasks such as geometry reconstruction, solar modelling, outcomes post-processing, and data visualization (Manni et al., 2023).

The hereby study investigates the preliminary application of the solar cadaster developed by Desthieux et al. (Desthieux et al., 2018) to high-latitude locations, with a focus on the municipality of Trondheim, Norway. The Web platform developed in Geneva *(https://apps.sitg-lab.ch/solaire/)* showcases the solar cadaster to a wide public audience and related energy and economic indicators by buildings. Although locations at latitude greater than 60°N have traditionally been assumed to receive low solar irradiation, recent studies have pointed out that these areas show only slight differences from Continental Europe in terms of annual solar energy potential (Formolli et al., 2021, 2023).

This study aims to investigate interoperability between software for handling CityGML files (i.e., open-source 3D city modeling format that enables the representation, storage, and exchange of virtual city model) and those for territorial data processing, such as ArcGIS Pro, for managing 2D/3D vector and raster data. By implementing a platform for urban solar energy planning in Trondheim municipality, this work emphasizes the significance of incorporating solar energy potential data into territorial regulatory instruments.

The literature mentions several examples of solar maps (Bieda & Cienciała, 2021; Fish & Calvert, 2016; Kanters et al., 2014). Some of them are also published on web platforms such as the Oslo Solkart *(https://od2.pbe.oslo.kommune.no/solkart/)* and the Norwegian Solkart *(https://solkart.no/search)*. These two examples represent the most recent web platforms, developed at high latitudes, in Norway. The reviews reveal the following gaps. For example, the solar cadasters implemented by Saretta et al. (Saretta et al., 2020) and Jurasz et al. (Jurasz et al., 2020) for the Swiss territory and Poland, respectively, are unable to visualize the usable area on roofs for PV installation. This consists of the portion of the roofs' areas more suitable for PV installations, excluding other service plants (e.g., chimney, storage/service equipment, swimming pool) and architectural elements (e.g., windows, overhanging parts) as well as poorly irradiated areas (i.e., shaded parts of the roof, unsuitable roofs' surfaces exposures and orientation). Current solar cadasters usually consider the entire roof area as equally useful (i.e., having the same solar energy potential level). However, to increase the reliability of the estimations, it is necessary to distinguish between area of the roof and usable area, as in London (Steadman et al., 2020) and Geneva (Desthieux et al., 2018) solar cadasters. There are very few studies and platforms providing estimations of the usable area, and none of them is developed for high-latitude applications. By examining the diverse web platforms, different levels of detail can be identified concerning the visualization of solar energy potential on the roofs. Among those, the most common two levels of visualization (LOV) are bidimensional (2D) exploiting either a solid (LOV1) or a gradient pattern (LOV2). The LOV1, which is the most common, corresponds to the lowest level of detail, and it associates a unique solar potential value with each roof slope. Conversely, the LOV2 enables visualizing the spatial variation of the solar energy potential with a color gradient. The level of visualization of this pattern strongly depends on the accuracy of the geometrical model. Solar cadasters with such level of visualization can show shadow cast from surrounding buildings as well as architectural and service plants elements of the roof (Amaro Silva et al., 2022), picturing the usable areas for installation of active solar systems. The Web platform of the solar cadaster of Geneva offers the LOV2 of visualization detail (Desthieux & Thebault, 2024).

Following the highlighted research gaps, the present study aims to investigate limitations and opportunities to improve the calculation and the visualization of the solar energy in the urban context, with a specific emphasis on high latitudes (Formolli et al., 2023). Identifying the available area for calculating the solar potential for a high latitude case study can be very valuable for advancing the research as there are still no studies with this level of detail.

Methods and materials

Case study selection

Three neighborhoods representative of low-, medium-, and high-density built areas in the city of Trondheim (N 63° 25' 41"), are selected as case studies to test the solar cadaster approach as introduced in Geneva. Their main characteristics are presented below in the Table 1 with the extension (m^2), the constructed volume (m^3), the built density, derived from the two previous values, and the normalized value of the density.

Table 1: List of the selected neighborhoods and information on their area and density

	Neighborhood area [m^2]	Buildings volume [m^3]	Density [m^2/m^3]	Normalized values
a	13662.12	5967.94	2.29	0.19
b	31098.13	4361.58	7.13	0.60
c	17665.09	2170.61	8.14	0.68

Besides the density, these neighborhoods differ in terms of their morphological characteristics and functions (Figure 1). The neighborhood (a) consists of a residential area with mostly two-story single-family detached houses, each with its private garden (i.e., high inter-building distances). Neighborhood (b) is also residential, but its houses are larger and taller compared to those in neighborhood (a). Gardens and courtyards are characterized by limited dimensions, thus increasing the risk of mutual shading between adjacent buildings. Finally, the neighborhood (c) is part of the downtown, and its buildings show a compact layout with small inner courtyards. In this area, stores open onto the ground level, while residential apartments are situated on upper floors.

Figure 1: Selected neighborhood (source: Google Earth). a) Pappenheim (low density), b) Rosenborg (medium density), c) Sentrum (high density).

Workflow

The workflow for the preliminary application of the solar cadaster platform developed by Desthieux et al. (Desthieux et al., 2018), at high-latitude locations, is outlined in Figure 2.

The solar model, encoded in JAVA, serves as the simulation engine, and constitutes the core of the workflow. Running it requires meteorological and geometrical input data. The meteorological input data are retrieved through the Meteonorm software version 7.3 *(https://meteonorm.com/)* provides statistical weather data representative of the period from 1990 to 2010 for a given location. Hourly data are averaged by month to shorten the dataset from 8,760 to 288 values. The geometrical input data consist of (i) digital surface model (DSM) of the analyzed neighborhoods for shadow casting, and the calculation slope and aspect on the area, (ii) the Shapefile containing 2D representation of buildings that provide an identifier and geometric data for each building, and (iii) the 3D model of the neighborhoods in CityGML format generated through the automated reconstruction technique from Kong and Fan (Kong & Fan, 2024). These are processed in ArcGIS Pro environment. Once the preparation of the input file is finalized, the solar simulation engine is started. The solar model is based on algorithms encoded in JAVA for the calculation of hourly, monthly, and yearly solar irradiation impinging on the studied area. The results are stored in Tag Image File (.TIF) format and can be visualized in ArcGIS Pro, utilizing various color gradients to represent the corresponding solar energy potential.

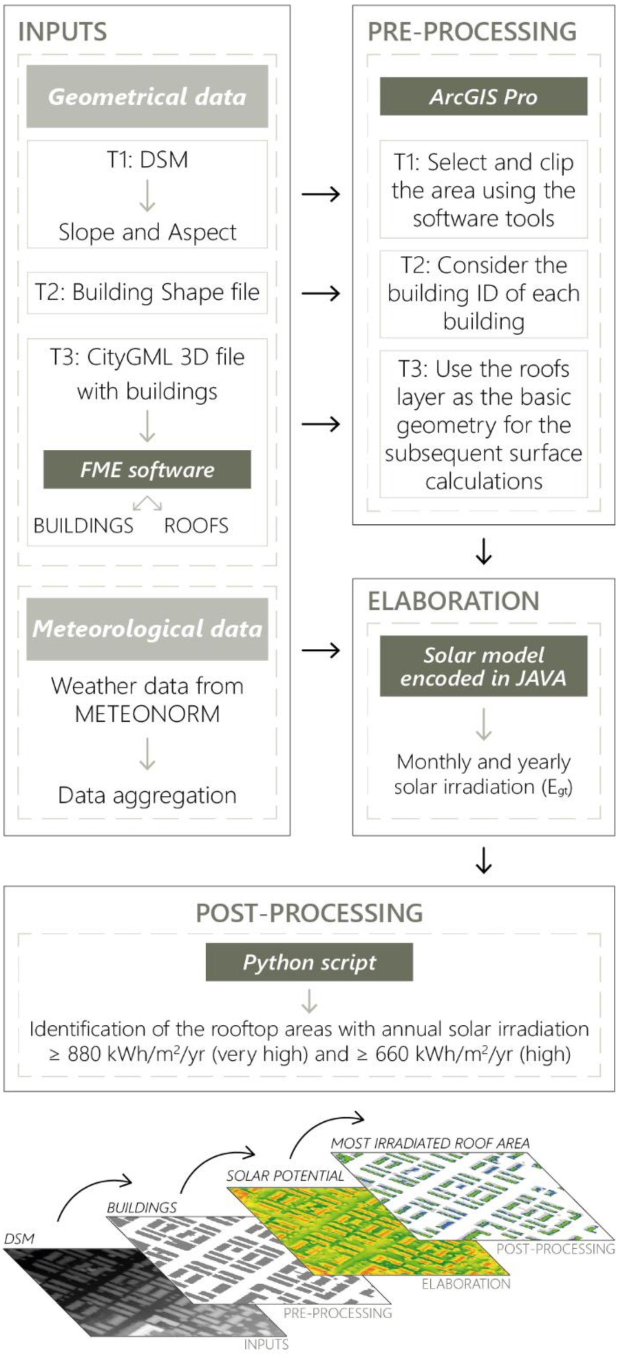

Figure 2: Workflow of the methodology developed in this study.

Following this, outputs from the solar model are post-processed to extract irradiation results on the roofs and identify the most suitable area on each roof for the installation of solar panels. Such an area consists of optimally exposed portions of the roof where there are no obstructions such as chimneys, roof windows, services, and machinery, hindering the installation of solar panels. Optimal exposition to solar irradiation is defined according to the threshold values identified for high latitudes in Lobaccaro et al. (Lobaccaro et al., 2019). Here in particular, the solar energy potential of any surface is labelled as 'very high' when the global tilted irradiation is greater than 880 kWh/m^2/yr; while it is classified as 'high' for global tilted irradiance amounts higher than 660 kWh/m^2/yr and lower than 880 kWh/m^2/yr. The range of low, medium, high, and very high solar irradiation is calculated based on the annual solar irradiation values for each surface, which are imported into 3D modelling software. The annual solar irradiation values are divided into five categories, for high latitudes: very low (0-220 kWh/m²/year), low (220-440 kWh/m²/year), medium (440-660 kWh/m²/year), high (660-880 kWh/m²/year), and very high (880-1.100 kWh/m²/year). These categories are determined based on the average values of solar irradiation in the middle point of each building's roof surface.

This part of the process (i.e., identification and classification of the most suitable area of the roof for solar panel installation), is conducting using a Python script. It represents a propaedeutic step for estimating the productivity of a potential PV system installed in the optimally irradiated portion of the roof.

The workflow is articulated and fragmented due to the utilization of different software and codifications, and it requires a high level of interoperability to integrate various type of information (i.e., meteorological, geometrical, and territorial vector and raster data) and data from different sources (e.g., HOYDEDATA.NO *https://hoydedata.no/LaserInnsyn2/*). This highlights the interdisciplinary and multi software domain of this research.

For this study, neighborhoods with an area ranging from 0.014 km^2 to 0.018 km^2 were selected to reduce the computational time for the solar analyses, compared to the whole city territory (340 km^2). Here the required time is represented by the time that the operator needs to manually perform the pre-processing tasks (T1-T2-T3). For each neighborhood, this can be estimated in 20 to 30 minutes. Considering the whole city of Trondheim, after the pre-processing time, needed for the selection of the different tiles, a total of around 50 hours are needed for the calculation of the solar potential results.

Pre-processing: preparation of input data for the solar modelling

Weather data are retrieved through Meteonorm software by choosing the nearest available weather station to the center of the city of Trondheim. The data are collected by the meteorological station at Værnes airport, located 35 km outside of the Trondheim municipality. The weather data file includes information about month of the year, hour of the day, global horizontal irradiation (Gh), diffuse horizontal irradiation (Dh), beam normal irradiation (Bn), and extraterrestrial irradiation (I_0). As mentioned in the workflow section, the solar analysis is conducted considering the average hourly values by month, rather than analyzing all days of the year (288 datapoints instead of 8,760). This permits to reduce both computational time and Central Processing Unit (CPU) requirements. The weather data is stored in a CVS format file. The other input data for initializing the solar model is related to the neighborhood geometry.

DSM, Slope, and Aspect. The DSM data of the studied area is provided by The Norwegian Mapping Authority *HOYDEDATA.NO* in .TIF format with one-meter spatial resolution. The three case study neighborhoods are extracted from the Trondheim DSM file. Edge dimension of the three clipping masks range from 220 m to 420 m. To create the new DSM (i.e., the clipped DSM file of the investigated neighborhood), slope, and aspect files ArcGIS tools are used. The raster pre-processing outputs are stored in .TIF format: the DSM file has the pixel type of 32-bit float, and both slope and aspect files have a pixel type of 16-bit signed.

Building Shapefile. This is a two-dimensional file containing the building layouts of the city of Trondheim. It is retrieved from the national territorial database *GEONORGE* (FKB-Buildings Dataset, *https://kartkatalog.geonorge.no/metadata/fkb-bygning/8b4304ea-4fb0-479c-a24d-fa225e2c6e97*), and it contains information about the identifier for each building (i.e., LOKALID). The building shapefile of Trondheim is also clipped to isolate the three neighborhood case studies.

CityGML file. A Level of Detail 2 (LoD2) building model for the urban area of Trondheim is created through two main steps: (1) roof plane segmentation from building point clouds conducted by LIDAR airborne plane survey and (2) roof line topology-based building model creation in LoD2. A deep learning-based method (Zhang & Fan, 2022) was applied to automatically segment the building point clouds into roof planes. The obtained roof plane information served as the basis for reconstructing 3D roof structures and subsequently creating building models. In the second step, the LoD2 building models were created using roof line topologies (Kong & Fan, 2024). This process brought to the automatic reconstruction of building models in LoD2 for the Trondheim urban area. A file in CityGML format was exported from this model, containing three-dimensional information of the buildings. Using the FME software, it is divided into two separate outputs: one for buildings and another for roofs. In this study, only the second file (concerning the roofs) is considered. This was used as the geometric basis of the subsequent solar analyses.

Other studies developed in Europe (Adjiski et al., 2023) and in Asia (Dahal et al., 2021) use similar approaches for creating the geometrical models from LiDAR data as well as for identifying the best exposed portions of the roof through Geographic Information System (GIS) tools.

Elaboration: solar radiation modelling on the studied area

The JAVA-based solar model is initialized with the files described in the previous section. Additionally, information concerning the geolocation of the case studies (i.e., longitude, area of the studied zone, DSM resolution) is manually set, allowing for a more accurate estimation of the global tilted irradiation. It processes hourly solar radiation for each component: direct, diffuse and reflection, as well as shadow casting impacting direct (hourly-based) and diffuse, based on Sky View Factor (SVF), components. The solar modelling approach is introduced in Desthieux et al. (Desthieux et al., 2018).

Outcomes from the elaboration stage consist of 14 files in .TIF format, including a solar irradiation map for each month (12), the annual solar irradiation map (1), and the SVF map (1). These files are in a gradient form and permit to visualize the solar energy potential of roof and ground surfaces.

Post-processing: calculations and visualization in GIS

The annual solar irradiation map is post-processed to identify the most suitable areas which are available for PV installation. The thresholds defined in the workflow section are considered to extract the highly (global tilted irradiance within the range 660-880 kWh/m^2/yr) and very highly (global tilted irradiance within the range 660-880 kWh/m^2/yr) irradiated portions of the roofs. Therefore, the potential for energy generation through PV panels is investigated for these areas. (Lobaccaro et al., 2019)

For extracting the roof areas with high and very high solar potential, the annual solar irradiation map is multiplied by a clipping mask based on the roof footprints. The highly irradiated areas are highlighted by selecting raster pixels corresponding to irradiation amounts greater than 660 kWh/m^2/yr. Then, the same procedure is reiterated considering the threshold of 880 kWh/m^2/yr for very highly irradiated roofs.

Additionally, the raster pixels representing roof elements which can obstacle the installation of PV panels (i.e. ventilation systems, mechanical bodies, chimneys) are filtered out. A new polygon surface is created from these pixels and subtracted from the roof footprints, considering an inner buffer of 0.5 m, as the solar panels could not be installed in proximity of the building edges. The identification of the most adequate areas for PV installation is completed by removing from the analysis all the polygons with an area of less than 5 m^2. These surfaces are deemed too small for installation of PV systems. Finally, the solar PV production is calculated considering the available and optimally exposed areas of the roofs, as well as the characteristics of the installed PV panels. In this study, the monocrystalline PV is considered, with a peak power of 220 Wp/m^2 based on the most powerful models available on the market. Although flat roof configuration is not present in the investigated neighborhoods, it is worth mentioning that the potential PV energy production of flat roofs is quantified by assuming that PV panels are installed with a default inclination ranging from 10° to 15°. A transposition factor (FT) accounts for this aspect. Indeed, the use of flat roof configuration is becoming increasingly common at high latitudes, owing to the development of effective techniques for mitigating the accumulation of snow.

Results and Discussion

Solar irradiation analysis

Results about the estimated annual solar irradiation for the three case study neighborhoods resulting on the annual solar irradiation values range between 0 kWh/m^2/yr and 1,170 kWh/m^2/yr (Figure 3).

In neighborhood ‘a’ (low-density), most of the surfaces are optimally exposed to solar irradiation. In fact, the houses are small and far, while streets are wide, allowing for a better solar accessibility. In neighborhood ‘b’ (medium-density), the areas subject to high solar irradiation are fewer and limited to south-exposed roof slopes. In the neighborhood ‘c’ (high-density), the rooftop areas suitable for PV installation are minimal due to mutual shading among buildings.

The results of this approach demonstrate the importance of conducting detailed solar analyses within urban environments, utilizing interoperable software.

Determination of suitable areas for PV installation

Solar irradiation outputs are post-processed to exclude parts of the roof that are either unavailable or characterized by global tilted irradiance lower than 660 kWh/m^2/yr. These surfaces are shown in differentiating between highly and very highly irradiated surfaces (Figure 4) (see the Methods and Materials section for the applied thresholds). The numerical results concerning the surface area are reported in Table 2.

Table 2: Calculation of total roof areas and actual usable parts after the analysis

	Total roof area (m^2)	Available area with E_{gt} > 660 kWh/m^2/yr (m^2)	Available area with E_{gt} > 880 kWh/m^2/yr (m^2)
a	2069.45	1023.44	400.20
b	2546.77	1121.32	545.37
c	1666.46	688.67	114.01

Results highlight the differences that exist among the investigated neighborhoods in terms of solar accessibility and solar energy potential. When considering the area of highly irradiated surfaces, this ranges from 40% (neighborhood ‘c’) to 50% (neighborhood ‘a’) of the total neighborhood area in each case study. Conversely, the portions of roofs with a very high solar potential varies between 6% (neighborhood ‘c’) to 20% (neighborhood ‘b’) of the total neighborhood area (Table 3).

Table 3: Percentages of usable area after changing the minimum irradiance threshold

	% of usable area with E_{gt} > 660 kWh/m^2/yr	% of usable area with E_{gt} > 880 kWh/m^2/yr
a	49.45 %	19.34 %
b	44.03 %	21.41 %
c	41.33 %	6.64 %

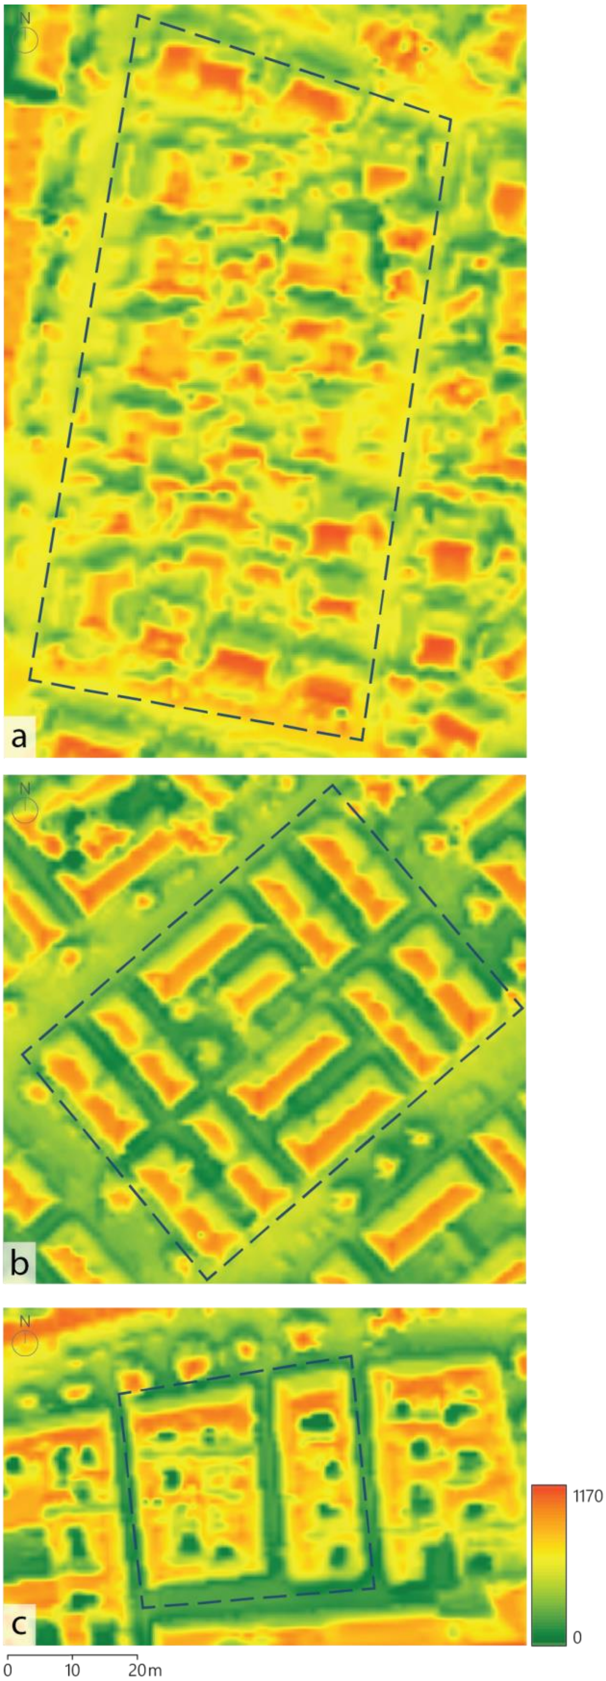

Figure 3: Annual solar irradiation (kWh/m^2/yr) calculated in the three neighborhoods.

Figure 4: Available roof area resulted considering E_{gt} higher than 660 kWh/m2/yr and 880 kWh/m2/yr.

The limited number of neighborhood case studies (3) prevents conducting robust correlation analysis between neighborhood density and the total area of available surfaces for PV installation. Nonetheless, it is worth highlighting that, among the percentages reported in Table 3, the lowest value is always associated to the high-density neighborhood.

This is due to (i) the proximity of the buildings, which facilitates mutual shading, and (ii) the lower ratio of the roof area to the total area of the building's envelope, resulting in a greater presence of elements installed on a rooftop compared to neighborhoods ‘a’ and ‘b’.

Comparison with existing solar modeling tools

ArcGIS geoprocessing tools such as the Raster Solar Radiation tool *(https://pro.arcgis.com/en/pro-app/latest/tool-reference/spatial-analyst/raster-solar-radiation.htm)* allow for conducting solar analyses with shorter computational time. However, they require the utilization of other models for calibration (Choi et al., 2019; Kausika & van Sark, 2021). Furthermore, those methods are characterized by a low level of users’ customization (i.e., forced data inputs) of the simulation parameters, particularly, the temporal resolution that is fixed to one year. The use of more interoperable software permits to perform sub-yearly analysis, allowing the customization of input parameters such as weather data sources and time intervals.

Two online platforms for the visualization of the solar potential of roof surfaces are already available in Norway. These are characterized by different spatial scales: the Solkart spans across the whole country, while the Oslo Solkart covers the Oslo municipality. A visual comparison of the national Solkart and the solar cadaster approach applied in this study is shown in Figure 5.

There is a difference in the spatial resolution of the output data. The Solkart shows the solar potential of any roof slope as uniformly distributed, providing a single solar irradiance value for each surface. The Oslo Solkart has gradient values, but both existing Solkart neglect the identification of the rooftop areas suitable for PV installation considering the presence of obstructions or lower level of irradiation. The presented approach, on the other hand, provides a solar irradiance value for each pixel of the neighborhood’s raster image, presenting a heterogenous spatial distribution of the solar irradiation on any rooftop slope. The calculation of the irradiation value on each part of the roof made it possible to identify the areas that are exposed to irradiation greater than 660 kWh/m^2/yr and 880 kWh/m^2/yr, highlighting the area available for new installations.

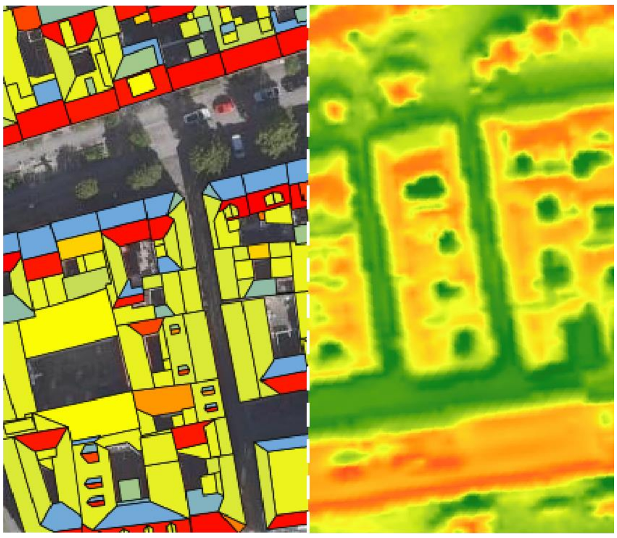

Figure 5: Visual comparison between the Solkart (left) and the solar cadaster approach from (Desthieux et al., 2018) *(right), applied to neighborhood 'b' (medium density).*

Finally, while the solar analysis performed with the Solkart does not account for the presence of trees, the method developer in the solar cadaster from (Desthieux et al., 2018) demonstrates the capability to process shadows casted from urban greenery included in the DSM.

Limitations of the study

This research study has three main limitations. Firstly, the weather data retrieved from Meteonorm v7.3 are collected by the meteorological station at Værnes airport, located 35 km outside of the Trondheim municipality. Indeed, this is the closest weather station to Trondheim which is available in Meteonorm database. Meteonorm was chosen over local weather stations to ensure a generic and easily replicable workflow for other case studies. Having more local data would allow for a more accurate analysis. Secondly, developing the process by implementing multiple software and tools allowed the results to be detailed, but at the same time having all the different working environments and code programming languages led to a fragmented process. The process is not automated, and the file recognition steps need to be filled in manually when switching from a software to another. Finally, only three case studies are considered for the calculation of the available roof area for PV installation. This limits the capability of identifying strong correlations between the model outputs and neighborhood density. Increasing the number of neighborhood case studies and expanding the analyses to the whole city of Trondheim can reinforce the conclusions drawn.

Processing the whole city of Trondheim will require to use the GPU machine installed at HEPIA (Stendardo et al., 2020), as for the solar cadaster in Geneva, which in particular allows to speed up the calculation of shadows implemented in the CUDA language.

Processing the solar analysis of a tile with a surface area of 9 km^2 takes approximately from one 1 to 1.5 hours. Therefore, analyzing the whole city of Trondheim, which has an area of 340 km^2, would take from 50 to 55 hours, which is acceptable for such an area. Computational time could be improved through parallelization.

Conclusions

The solar cadaster approach developed by Desthieux et al. (Desthieux et al., 2018) is applied to three neighborhoods in Trondheim (i.e., low-, medium-, and high-density neighborhoods). The proposed method is at the forefront of interoperability between software for managing urban geometry models and those for processing territorial data. The main findings of the study concern the identification of the best irradiated portion of the roofs suitable for installing PV systems. Results demonstrate the need for more refined analyses compared to existing online platform in Norway. Achieving this level of precision currently requires a combination of various software and types of information (i.e., meteorological, geometrical, and territorial vector and raster data). From the social perspective, the proposed solar cadaster approach aligns with the ongoing trend toward smart and sustainable cities. Informing citizens and municipalities about the solar potential of the building stock reflects a commitment to harnessing affordable and user-friendly technology for creating more efficient, sustainable, and livable built environments (Xue et al., 2021). Future advancements in this field may concern (i) enhancing the workflow through automation, parallelization, and reduction of the fragmentation to reduce the computational time especially for the whole city territory; (ii) exploiting the use of the local data and validating the results against real measurements; (iii) extending the analysis to the entire city territory of Trondheim; and (iv) creating an accessible online platform (i.e., solar cadaster) at the cityscape level to engage public and private stakeholders and the interaction with the individual users. Additionally, (v) extending the analysis to vertical surfaces (i.e., the facades) by including the optical properties of materials and the detection of architectural elements (i.e., windows, doors, balconies, overhanging parts) in the calculation will be important to increase the level of information on the most irradiated parts of the facades, especially at high latitudes where the vertical surfaces received the annual highest irradiance (Formolli et al., 2023). Therefore, it will be necessary to progress the research about material detection and image recognition techniques.

INTELLIGENT RETROFITS IN RESIDENTIAL BUILDINGS: A KNOWLEDGE -BASED APPROACH

Sobia Bano, Usman Ali, Divyanshu Sood and James O'Donnell
School of Mechanical and Materials Engineering and UCD Energy Institute, UCD, Dublin, Ireland

Abstract

Building Life Cycle Assessment (LCA) is crucial to mitigate the environmental impact of residential retrofits. However, a significant gap exists in evaluating the complexity of building life cycles in the context of residential renovations. The proposed intelligent Knowledge Base System methodology integrates existing building materials, stock data, typologies, and retrofit scenarios, employing a hybrid approach that combines rule-based, case-based, and frame-based systems for comprehensive life cycle assessment. The case study focuses on retrofitting the semi-detached housing typology, transitioning from a boiler to a heat pump, and results in a reduction of total carbon emissions to 184 tCO_2e and 90 tCO_2e over 60 years. This study aids energy policymakers, urban planners, and researchers by offering an intelligent framework to promote eco-friendly renovations and advance sustainable building practices.

Introduction

Buildings are a major source of emissions, accounting for 39% of global energy-related carbon emissions, split between operational emissions (28%) and emissions from materials and construction (11%) (WGBC, 2023). The entire life cycle of a building, from material extraction to demolition, contributes to its carbon footprint. Emissions are categorized into operational (from daily operations) and embodied (from materials, construction, transportation, and demolition) (Fenner et al., 2020). Addressing these emissions is crucial for achieving near-zero carbon targets, requiring effective methods and strategies to assess and reduce carbon emissions throughout a building life cycle assessment (LCA).

A big challenge in applying LCA during initial design or retrofitting is the scarcity or complexity of data (Kadrić et al., 2023; Roberts et al., 2020). This complexity hinders stakeholders from developing and implementing effective retrofit measures (Zuo et al., 2017; Najjar et al., 2019). Conducting LCAs to upgrade residential building stock is crucial, as it allows for assessing long-term environmental and cost impacts throughout the buildings' lifespan, as discussed previously, and all subsequent phases. Despite the widespread adoption and standardization of LCA methodologies and the growing availability of data through tools like Environmental Product Declarations (EPD), a significant research gap still needs to be addressed. This gap mainly lies in integrating and interpreting complex data for specific scenarios. The complexity increases when dealing with residential renovations, where factors such as renovation type, materials used, and the building's operational phase add complexity (Roberts et al., 2020).

Furthermore, despite the benefits of sustainably retrofitted buildings, key stakeholders often lack a system to generate new knowledge while incorporating the entire lifecycle of a building. This includes selecting sustainable materials and transferring related information between stages. However, integrating complex data across different LCA phases and needing a flexible and scalable solution represents a significant research gap in Building LCA (Hollberg et al., 2021).

The importance of comparing different existing LCA analyses of buildings has been widely acknowledged. For instance, Röck et al. (2020) analyzed 238 buildings from 54 scientific articles, focusing on embodied and operational emissions. They emphasized the need for comparative LCA studies due to varying energy performance standards. Previous research has concentrated on implementing LCA frameworks in buildings to assess environmental impacts. Waldman et al. (2020) proposed a methodology for assessing construction materials during the specification and procurement stages of LCA. Balouktsi et al. (2020) explored the level of designers' awareness of environmental performance assessments and LCA in buildings. A study by Sharma et al. (2011) demonstrated large discrepancies in LCA results for 13 buildings, highlighting that commercial buildings have a greater environmental impact than residential ones. Similarly, Säynäjoki et al. (2017) reviewed 116 buildings and compared their GHG emissions during pre-use life cycle stages, finding significant inconsistencies in LCA results, ranging from 0.03 to 2.00 tons of CO_2 eq. per m^2. Data reliability and geographic relevance are crucial for accurate LCA methodologies across different buildings. Another challenge is the lack of collaboration among LCA practitioners, including designers, architects, building consultants, and engineers. Bridging this gap and promoting collaboration is a key objective of this study.

A survey by Jusselme et al. (2020) highlighted the time-consuming nature of LCA in the design stage, ranging from 18 to 33 hours from data collection to result interpretation. This adds to the time and cost of the process. Identifying strategies for efficient LCA analysis is therefore crucial. Various LCA databases, such as One Click LCA, Eco Invent, SimaPro, and the ULSCI database, offer different strengths and weaknesses. Each database, like Eco Invent v3 with its 10,000 interlinked datasets, or SimaPro, suitable for cradle-to-grave assessments, has unique features

(Wernet et al., 2016). Mohammadpourkarbasi et al. (2023) performed a comparative study of retrofit approaches for life cycle carbon assessment of decarbonizing UK's hard-to-treat homes. However, integrating data from multiple databases, establishing relationships, and reducing redundancies and discrepancies can greatly benefit decision-makers and stakeholders. Furthermore, studies rely on predefined retrofit scenarios and require intelligent solutions to recommend environmentally friendly retrofit scenarios for buildings based on their requirements.

The aim of this study is to propose a methodology for an intelligent Knowledge Base System (iKBS) for residential building LCA. The knowledge-base system integrates and analyzes complex, various data sources using knowledge acquisition, knowledge pre-processing (transforming unstructured data into structured data), and knowledge management. A novel feature of this system is knowledge inference, specifically tailored to generate new pieces of information from existing data. Furthermore, this research compares various knowledge-based approaches, such as rule-based, case-based, and frame-based systems for building LCA. This comparative analysis led to the development of a recommendation system for stakeholders that provides deep insights into the embodied energy aspects of residential renovations, a critical factor in understanding and improving the environmental performance of the building stock. The semi-detached housing typology case study shows that combining various knowledge leads to low-energy, cost-effective retrofit material recommendations.

Traditional LCA methods often rely on static, linear approaches to assess the environmental impacts of building projects. These methods may not adequately capture the complexities and interdependencies inherent in building life cycles, particularly for residential renovations. They typically struggle with dynamically incorporating new data or adjusting to novel scenarios without substantial manual intervention that accounts for updates during the life cycle. This can lead to inaccuracies in modeling the environmental impacts of different materials, processes, and retrofit options. In contrast, iKBS offers a dynamic, adaptive, and comprehensive framework for LCA. iKBS is built upon a hybrid model that combines the strengths of rule-based, case-based, and frame-based reasoning to handle diverse data types and complex analysis scenarios. The iKBS is capable of automating the data acquisition, preprocessing, and analysis processes, significantly reducing the time and effort required while enhancing the accuracy and relevance of the assessments. This integration allows for the sophisticated handling of diverse data types and complex analysis scenarios, facilitating the assimilation and processing of vast amounts of building material, stock data, residential typologies, and retrofit scenarios. the proposed intelligent framework can adapt and learn from new information, providing a more nuanced understanding of environmental impacts and facilitating the generation of actionable recommendations tailored to specific renovation projects.

The paper follows a structured format, with Section 2 presenting the methodology employed in the research. Section 3 examines a comprehensive Irish case study, providing real-world context for the study's findings. Finally, Section 4 concludes the paper and outlines potential avenues for future research.

Methodology

This paper presents a comprehensive methodology for an intelligent Knowledge-based System to facilitate detailed Life Cycle Impact (LCI) Assessments for the building and construction sector, integrating environmental and economic performance metrics for sustainable decision-making (Figure 1). The proposed development for residential building stock, based on the ISO 14040/44 standards (Principles and Framework for Life Cycle Assessment), comprises four phases: goal and scope definition, life cycle inventory, life cycle impact assessment, and interpretation. Each phase is crucial and builds upon the previous one, ensuring a comprehensive and systematic approach to assessing the environmental impacts of residential building renovations.

The proposed methodology encompasses several key steps: 1. Goal and Scope Definition to outline the study objectives, 2. Development of a Knowledge-based System for LCI to gather relevant data or knowledge; 3. Integration of Life Cycle Impact Assessment via an Inference Engine, and 4. Creation of an LCA Interface for Recommendations, facilitating informed decision-making. This comprehensive approach ensures thorough analysis and informed choices throughout the lifecycle assessment process, emphasizing requirements, steps, and effective implementation strategies.

Goal and Scope Definition

The methodology begins with defining the goal and scope of the building life cycle assessment. The goals are to understand its initiation reasons, identify potential applications, and specify the target audience. The scope includes specifying the application, approach, data requirements, study period, functional unit, and system boundary. These parameters are essential for guiding the overall development process and ensuring the assessment aligns with the intended purpose. The goal and scope definition serves as the foundation for developing an iKBS to strategically identify areas for enhancement in the building's environmental performance. Furthermore, the methodology is beneficial in determining the best retrofit options, providing in-depth cost-benefit analysis, and conducting comprehensive sustainability assessments by defining proper goals and requirements.

Knowledge-based System for LCI Development

Life Cycle Inventory (LCI) is a core step of LCA and represents the quantification of inputs and outputs for a product throughout its life cycle (Wernet et al., 2016). In the

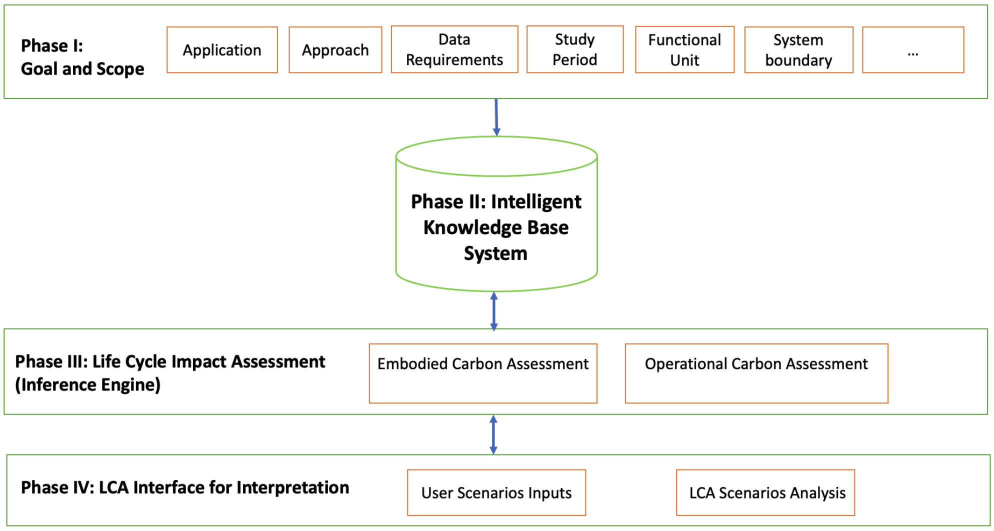

Figure 1: Methodology for intelligent Knowledge-based system for comprehensive life cycle assessment of residential buildings

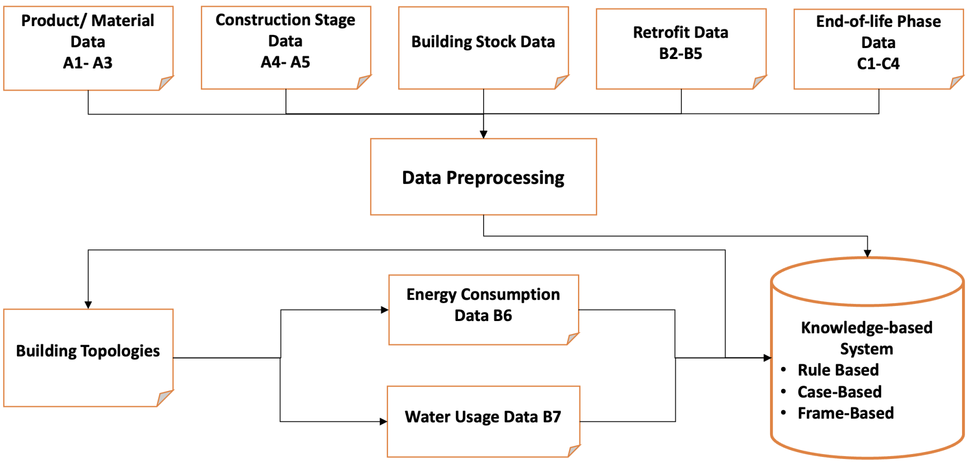

Figure 2: Sub-methodology for knowledge-based system for life cycle inventory development

context of buildings, LCI data include the energy, materials, and emissions associated with the construction, operation, maintenance, and eventual deconstruction of buildings. Several databases provide LCI data with embodied carbon values for various construction materials and processes, such as the Inventory of Carbon and Energy (ICE) database from the University of Bath (ICE, 2024), which can be used exclusively for calculating embodied energy from a prospective perspective, and Ecoinvent (Ecoinvent, 2024) considered to be the largest transparent unit-process. Similarly, various regions and organizations maintain databases of EPDs, which provide standardized LCA-based reports for specific products, including many construction products (Feng et al., 2023). Generally, Building LCA is categorized into different stages: A1-A3 for material extraction and transport, A4-A5 for construction and waste management, B1-B7 for use and renovation, C1-C4 for end-of-life disposal, and D for the environmental benefits of recovery. The process consists of multiple steps: Knowledge Acquisition and Preprocessing, Building Typologies, Knowledge-Based System Development, and Inference Engine for assessments (Figure 2).

Knowledge Acquisition and Preprocessing

The knowledge Acquisition phase for the iKBS involves gathering a wide range of information to create a comprehensive understanding of various aspects of building construction and maintenance. The knowledge acquisition in this phase is segmented into various categories:

- Product/Material Data (A1-A3): This involves gathering data on all materials and products used in the construction process, from extraction to processing.
- Construction Stage Data (A4-A5): Data related to the construction activities, including transportation and on-site processes.
- Building Stock Data: Information on the existing buildings, including their types, ages, and materials.
- Retrofit Data (B2-B5): Information on any renovation or updates made to existing buildings.

- End-of-life Phase Data (C1-C4): Data concerning the demolition, waste processing, and disposal or recycling of building materials or products.

The acquired knowledge undergoes a pre-processing stage to ensure it is consistent, accurate, and relevant for developing the iKBS. The methodology uses different data pre-processing methods such as data cleaning, data transformation, and data integration. The fuzzy-based method is used for identifying and merging records that refer to the same entities across different databases. This step is crucial to ensure the iKBS can effectively use the knowledge for intelligent decision-making in construction projects, sustainability assessments, and lifecycle management of buildings.

Building Typologies

Buildings often share common characteristics and can be classified into a building typology. This can also be referred to as a reference building, which is a representative structure capturing the typical characteristics and performance of a specific category or group of buildings within a larger building stock. This data can be sourced from established national building stock databases, such as TABULA or EPC databases (Ali et al., 2024). Building typologies data is further used for the B1 stage, which evaluates the building's performance in terms of energy and water usage. These data can also be generated using a thermal simulation engine such as EnergyPlus and IES for the generation of energy and water consumption data based on retrofit scenarios (Ali et al., 2024).

Intelligent Knowledge-based System Development

The proposed iKBS is an advanced framework to analyze the complex decision-making process. This process integrates pre-processed and simulated data from the Life Cycle Inventory Development, accommodating the vast array of data and variables in assessing a building's life cycle. The system comprises various intelligent knowledge representation and recommendation methods, including Rule-Based, Case-Based, and Frame-Based systems. Rule-based systems express knowledge concepts as a conjunction of conditions and conclusions (Santos et al., 2020). A rules-based system can be developed for LCA in residential buildings to evaluate environmental impacts based on specific criteria, such as material selection. For instance, a rule might state, *"If a building's construction year is old, then the materials used in the building are of low performance."* Case-based reasoning solves new problems by extracting and applying solutions previously adopted for similar problems (Zhao et al., 2019). In the context of LCA, past LCA studies or available data from similar residential buildings can be used to predict the environmental impact of a new building project. Frame-based systems use structured templates or frames to represent knowledge and infer new information based on existing structures and relationships within the frames (Nazaruks and Osis, 2021). These systems use detailed, available data in structured frames or templates. Each frame can represent different aspects of LCA, like materials, energy efficiency, or water usage, with slots for specific attributes and values.

Typically, KBS (Knowledge-Based Systems) stores all data in databases such as PostgreSQL and MySQL for structured data with well-defined schemas, and MongoDB, Cassandra, or Couchbase for unstructured or semi-structured data. In this paper, MongoDB and Python are used to implement a hybrid approach of Rule-Based, Case-Based, and Frame-Based systems that store different types of unstructured or semi-structured data.

This study comprehensively assesses each system based on accuracy, complexity, flexibility, and scalability. However, due to the complex nature of building lifecycle assessment and data requirements, this study proposes a hybrid approach for effective life cycle assessment. Furthermore, the hybrid approach offers a comprehensive, adaptable, and flexible method to handle unique scenarios, making it a robust solution for sustainable building practices.

Life Cycle Impact Assessment (Inference Engine)

An inference engine that evaluates the environmental implications of a building throughout its life cycle. Environmental performance assessment focuses on embodied energy (energy used in the production of the building materials) and operational energy (energy used during the building's operation).

LCA Interface for Recommendation

Stakeholders can input or query different scenarios to the inference engine to see how changes might affect the life cycle impacts. The inference engine gives recommendations based on input or query to analyze various scenarios to help decision-making. The system provides a comprehensive analysis that enables users to accurately interpret the life cycle impacts of buildings. It allows for assessing different scenarios and helps make informed decisions to improve environmental and economic performance.

The LCA interface empowers stakeholders to input or query diverse scenarios into developed iKBS using an intelligent inference engine. Furthermore, the interface provides a detailed and comprehensive analysis of environmentally sustainable and efficient materials. The IKBS is a pivotal tool in driving eco-friendly viable building and infrastructure development practices.

Case Study

This case study focuses on analyzing the impact of renovation on the life cycle of an Irish semi-detached building. This study demonstrates the application of an Intelligent Knowledge-based System (iKBS) for detailed residential building LCA (Figure 3).

Intelligent Knowledge-based System Development

This case study aims to evaluate the environmental impact of existing Irish semi-detached typology and recommend the best materials and components for retrofits. The scope encompasses assessing embodied energy, operational en-

Table 1: Data knowledge requirement for Irish case study knowledge-base development

knowledge Requirement	Irish Case Study

Building Typologies	Irish TABULA, EnergyPlus

ergy, and potential retrofitting options for energy efficiency improvement. The study targets policymakers, contractors, and homeowners to provide insights into sustainable building practices. The scope of this case study includes specifying the application, approach, data requirements, study period, functional unit, and system boundary.

The knowledge-based development phase involves an extensive collection and analysis of knowledge for the life cycle of buildings, focusing on the context of Ireland. This process uses a variety of sources, including the Irish Energy Performance Certificate (EPC) database, the Irish database for embodied energy and materials, the International ICE database, and retrofit scenarios data relevant to Ireland (Table 1).

The knowledge of building materials for constructing Irish houses encompasses stages A1-A5 or C1-C5, ranging from raw material production to end of life. This information is gathered from the Irish National Material Database, the ICE, Ecoinvent, and TM65 databases. (ICE, 2024; Ecoinvent, 2024). These databases contained embodied energy and carbon emissions associated with different materials that contribute to global warming and climate change and information related to the transportation of materials and the actual on-site construction processes (Table 1). The building stock knowledge component offers detailed information about existing houses in Ireland, including their age, construction materials, and build type. This knowledge is collected from the Irish EPC database of 1 million buildings. Retrofit scenarios encompass information about renovations to enhance building energy efficiency collected from existing retrofit schemes in Ireland nationally (Figure 3)(CAP, 2024).

The study used typologies of existing residential buildings in Ireland from the TABULA project. These typologies aid in evaluating the buildings' energy and water usage, focusing on the usage data generation. TABULA provides typological data for the 34 Irish dwelling types across 10 age bands. The Irish TABULA project also provides baseline knowledge for building elements, such as exterior walls, roofs, windows, and floors. The baseline knowledge helps to identify recommended retrofit scenarios for target buildings. This study uses the EnergyPlus simulation engine for energy and water consumption, as well as B6 and B7 usage data generation based on retrofit scenarios.

The integration of acquired Irish knowledge within the iKBS begins with a critical pre-processing stage designed to ensure the accuracy and consistency of the data. This foundational step is crucial for preparing the information for sophisticated analysis and decision-making processes. The iKBS integrates pre-processed data and typologies knowledge using Rule-Based, Case-Based, and Frame-Based systems for intelligent decision-making. These knowledge-based approaches, commonly used based on existing studies, are considered optimal for Knowledge-Based Systems (Santos et al., 2020; Zhao et al., 2019; Nazaruks and Osis, 2021). In this study, MongoDB is used for storing knowledge because of its ability to handle unstructured or semi-structured data. This system enables the evaluation of environmental impacts based on criteria such as material selection and energy efficiency.

The Rule-Based system is pivotal in identifying construction materials used in typology, considering various attributes such as layers, thickness, conductivity, and cost. The Frame-Based system facilitates the retrieval of all data in frames, simplifying interaction with the inference engine for estimating total embodied energy and U-values. This study also compares the embodied carbon of materi-

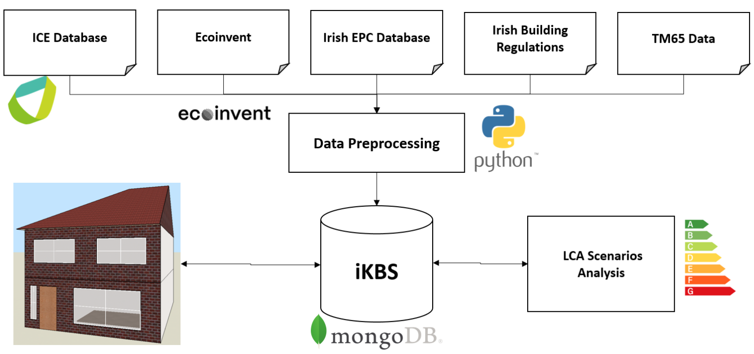

Figure 3: Irish case study knowledge-based development process diagram for LCA analysis

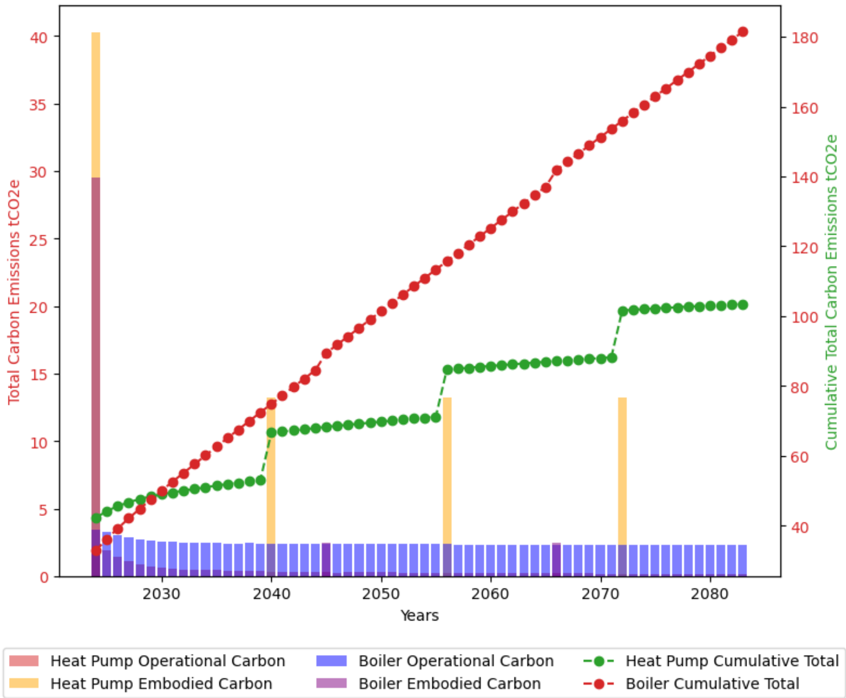

Figure 4: Long-Term impact of retrofitting measures on CO_2e emissions in semi-detached topology residential buildings: A 60-year lifecycle assessment

Table 2: Pre and post-retrofit scenarios for the semi-detached topology building for LCA analysis

	Pre-Retrofit	Post-Retrofit (Boiler)	Post-Retrofit (Heat Pump)
Wall U-value	0.6	0.21	0.21
Roof U-value	0.4	0.13	0.13
Floor U-value	0.64	0.21	0.21
Window U-value	3.1	1.6	1.6
Heating Efficiency/COP	0.7	0.9	3
EUI	290	148	78
Energy Rating	D2	B3	B1

als with those in the Irish material database and other available databases, such as ICE and Ecoinvent. The frame-based system organizes and stores data in a structured format known as frames, which facilitates the efficient retrieval and analysis of information related to construction materials.

Furthermore, the Case-Based system develops recommendations for stakeholders to find insulation materials with minimal embodied carbon. This system identifies similar cases using a fuzzy string-matching approach, helping to find materials by name or category. The fuzzy approach is the most robust in handling variations in input data and string matching, based on existing studies (Zhao et al., 2019). The case-based system uses historical knowledge of insulation materials to recommend options with minimal embodied carbon for new construction projects.

Overall, the hybrid approach is used in the inference engine to assess the environmental and economic impacts of the buildings. This integration offers a robust framework for intelligent decision-making, providing flexibility, adaptability, and comprehensive analysis. The system provides recommendations and a comprehensive analysis of existing and retrofit material, allowing users to explore various scenarios for improved environmental performance.

LCA for Semi-detached typology using iKBS

The case study of the semi-detached typology demonstrates how iKBS can lead to recommendations for materials with minimal embodied energy or operational energy for retrofitting. The typology of a semi-detached house built between 1983 and 1993 features cavity walls and pitched roofs with a floor area of 106.27 m^2. The pre-retrofit typology U-values are 0.6 $W/(m^2{\cdot}K)$ for walls, 0.4 $W/(m^2{\cdot}K)$ for roofs, and 0.64 $W/(m^2{\cdot}K)$ for floors, with double-glazed, PVC-framed windows at 3.1 $W/(m^2{\cdot}K)$, and a boiler efficiency of 70%, leading to an energy rating of D2 and a total Energy Use Intensity (EUI) of 290 $kWh/(m^2.yr)$. These figures indicate significant potential for improvement. The iKBS recommended various insulation materials based on their thermal conductivity and embodied energy values to enhance the U-values of the walls, roof, floor, and window (Table 2).

The iKBS recommends various insulation materials, including Extruded Polystyrene (XPS) and mineral wool, to improve the U-values of building structures such as walls, roofs, and floors. These recommendations based on Low thermal conductivity ensure that materials like XPS offer superior insulation performance, effectively reducing heat transfer through walls and floors. Furthermore, these materials enhance a building's energy efficiency and contribute to a more stable and comfortable indoor environment. On the other hand, mineral wool is highlighted for roof insulation due to excellent thermal resistance and ability to manage moisture, further optimizing the building's thermal performance. The iKBS aims to promote sustainable construction practices that minimize energy consumption and carbon footprint, aligning with broader environmental conservation efforts.

In this study, two heating system scenarios are considered for post-retrofit scenarios, such as employing a condensing boiler with 90% efficiency and an air source heat pump with a Coefficient of Performance (COP) of 3.0 (Table 2). The life cycle assessment of retrofitting measures in a semi-detached building, analyzed over a 60-year life span, highlights the significant environmental benefits of retrofitting despite initial increases in total CO_2 emissions due to embodied carbon from materials and heat pump installations (Figure 4). The analysis reveals a significant reduction in operational emissions post-retrofit when compared to both boiler and heat pump heating systems, validating the efficacy of retrofitting in reducing operational carbon.

Despite the initial environmental cost indicated by the surge in total emissions due to the heat pump (40 tCO_2e) and boiler installation (30 tCO_2e), the operational savings quickly compensate for these impacts, leading to a considerable reduction in the building's carbon footprint over the long term. The periodic accounting for the embodied emissions of heat pumps every 15 years and boilers every 20 years takes into account the replacement cycles of the equipment, underscoring the necessity of long-term sustainability planning.

Overall, the LCA demonstrates that retrofitting significantly contributes to environmental sustainability by lowering operational emissions, emphasizing the long-term benefits of such interventions in residential building management. Retrofitting with a boiler decreases the EUI from 290 to 149 kWh/(m^2.yr), enhancing the energy rating from D2 to B3, with a 184 tCO_2e emission. Similarly, Retrofitting with a heat pump reduces the Energy Use Intensity (EUI) from 290 to 78 kWh/(m^2.yr), upgrading the energy rating from D2 to B1 and resulting in a reduction of 90 tCO_2e emission.

This case study demonstrated the effective application of an iKBS in the context of Irish housing stock. The study provided valuable insights into sustainable building practices by integrating comprehensive data sources, highlighting areas for embodied energy efficiency improvements and potential retrofit options. The approach underscores the importance of detailed life cycle assessments in guiding sustainable decision-making in the building and construction sector.

The results show that iKBS enabled the quantification of energy and emissions savings with greater specificity, demonstrating significant improvements in energy use intensity and carbon emissions reductions through various retrofit scenarios. Traditional methods might not fully capture the nuanced impacts of different retrofit options due to complex interactions between various building materials, usage patterns, and lifecycle stages. This methodology offers a more dynamic and comprehensive tool for policymakers, urban planners, and researchers aiming to optimize residential renovations for sustainability and climate mitigation.

Conclusions

This study bridged a significant gap in Building LCA for residential renovations by integrating diverse data sources such as existing building stock data, residential typologies, retrofit scenarios, and building materials data into an intelligent Knowledge Base System (iKBS). This research has advanced the understanding of the environmental impacts of residential renovations. Knowledge-based system development represents a novel approach to assessing building life cycles, particularly in the national residential building stock context.

The comparative analysis of various KBS approaches, including rule-based, case-based, and frame-based systems, has provided valuable insights into operational and embodied energy aspects. This work is particularly noteworthy for contributing to eco-friendly renovation practices and advancing sustainable building methodologies. The findings of this study are a valuable resource for energy policymakers, urban planners, and researchers, offering a new and intelligent framework for promoting sustainable practices in the building sector.

Future work would expand the methodology's applicability by encompassing diverse geographic regions building typologies and retrofit scenarios thereby enhancing its utility and relevance. Furthermore, integrating emerging technologies such as machine learning and big data analytics could further refine the accuracy and efficiency of the LCA process. Collaborating with industry stakeholders and policymakers will be vital in implementing these advanced tools in practical scenarios. Finally, the ongoing evolution of this research can significantly contribute to the global effort to create sustainable and eco-friendly buildings.

Product and Process Modelling

AUTOMATED GEOMETRIC-SEMANTIC DIGITAL TWINNING OF STAIRCASES FROM DENSE LASER SCANNER POINT CLOUDS BY PARAMETRIC PROTOTYPE MODELS

Mansour Mehranfar[1], Alexander Braun[1], and André Borrmann[1]
[1]Technical University of Munich, Munich, Germany

Abstract

Digital Twins (DTs) have become as valuable tools for management, and operation of assets. A main challenge, however, persists in the automated creation of high-quality buildings DTs, providing both precise geometry and semantics. This paper introduces a novel hybrid bottom-up, top-down approach for the automated creation of DT models of staircase structures using laser scanner point cloud. The proposed workflow involves separating inclined staircase points, designing parametric DT models, and model fitting through an optimization process. The results demonstrate the effectiveness of the proposed with an average accuracy of about 4 cm in determining the dimensions of the model's elements.

Introduction

The automatic creation of DTs for the built environment has emerged as a prominent and demanding field within the AEC domain (Volk et al., 2014; Bosché et al., 2015; Drobnyi et al., 2023). A DT is a virtual replica of physical assets that facilitates real-time simulation and monitoring. DTs offer numerous possibilities for resource and facility management, enabling more intelligent analysis and interactions (Drobnyi et al., 2023). When it comes to creating DT models for exiting buildings with rich semantic content and coherent geometry, an important first step is to acquire relevant data, especially visual and spatial data. In this regard, laser scanning technology plays a crucial role, enabling the meticulous collection of point cloud data and the creation of virtual replicas for both indoor and outdoor environments (Noichl and Borrmann, 2022; Pan et al., 2023; Abdollahi et al., 2023; Martens and Blankenbach, 2023). This technology plays a pivotal role in advancing the domains of building performance and sustainability.

In the past decade, significant progress has been achieved in the field of point cloud processing techniques and 3D scene understanding methodologies, with a specific emphasis on automatically generating accurate geometric-semantic DT models from point cloud data. Nevertheless, developing a comprehensive and precise algorithm for this purpose has encountered numerous challenges, primarily arising from noise, clutter, obstructions, and the representation of volumetric-semantic models (Ochmann et al., 2016). Furthermore, most of the existing approaches have primarily focused on creating 3D models of structural elements such as ceilings, floors, and walls while neglecting the intricate modeling of other structural components, notably staircases, which play a pivotal role in the reconstruction of DTs for multi-story buildings (Nikoohemat et al., 2020). This oversight can be attributed to the inherent complexities associated with indoor scenes and the intricacies involved in reconstructing staircase structures (Schmittwilken et al., 2009). Staircase structures assume diverse shapes and configurations based on varying specifications, making the automatic reconstruction of 3D models a challenging task.

In the realm of urban planning and facility management, digital staircase models are vital for optimizing pedestrian flow and enhancing public safety. In this regard, the automatic creation of digital staircase models from point cloud data empowers facility managers and builders to conduct virtual walkthroughs, identify potential conflicts, and reduce construction and maintenance costs.

In the research presented in this paper, the primary objective is to introduce an automated workflow that combines both bottom-up and top-down approaches to extract staircase points within the indoor environment and generate parametric DT models with coherent geometry. The key contribution lies in utilizing domain knowledge to formulate parametric models for the building's staircase structures and subsequently fitting the designed rough models to point cloud data to achieve a close representation of reality.

Background and related work

Digital building twin creation

With the increase in demands for the creation of DT models for the built environment, indoor digital twinning has become an intensively researched topic in AEC domain (Borrmann et al., 2023). In this context, laser scanners and photogrammetry technologies are the most modern and efficient measurement tools, facilitating the acquisition of accurate geometric and semantic information, which are widely used in the realm of automatic creation of 3D digital models. However, despite all progress made, the automatic creation of digital building twin from point cloud data remains only partially resolved, and most developed methods are designed for specific types of buildings and restricted to reconstructing specific kinds of objects based on use cases.

In this regard, Xiong et al. (2013) proposed an automated 3D reconstruction framework utilizing a voxelized point cloud to identify patches, such as walls, ceilings, and floors, by adhering to boundary constraints. Monszpart et al. (2015) proposed the regular arrangements of planes (RAP) technique for reconstructing indoor 3D scenes using point cloud data. The proposed method uses local plane-based approximations and global inter-plane relations to simplify the arrangement of planes fitted to the points of the environment. Ochmann et al. (2019) proposed an innovative approach for reconstructing volumetric building DT models, encompassing floor, ceiling, and wall elements. They employed a linear optimization framework to disjoint distinct 3D spaces and determine the positions of common wall instances shared among them. Tran and Khoshelham (2020) employed a reversible jump Markov Chain Monte Carlo (rjMCMC) algorithm to facilitate the application of shape grammar rules in the procedural-based reconstruction of 3D indoor models from dense point cloud data. Abdollahi et al. (2023) introduced a progressive model-driven approach for the 3D modeling of indoor spaces employing watertight predefined models. This approach initially segmented spaces into rectangular and non-rectangular regions with an even number of sides. Subsequently, a point density occupancy map is used to enhance the level of detail in the intrusion and protrusion parts of Manhattan and non-Manhattan models.

Recent advancements in artificial intelligence (AI) and machine learning (ML) technology provide an effective solution for accurate point cloud processing, reducing the manual effort required in creating DTs. In this regard, Mehranfar et al. (2022) proposed a hybrid bottom-up, top-down method using AI semantic segmentation network to separate the 3D space in simple and complex indoor point cloud. Mehranfar et al. (2023) also combined domain knowledge in construction and architectural design with the capabilities of AI techniques in scene understanding to create highly parameterized building models with rich semantic and coherent geometry from dense point clouds. The proposed method employs the parametric modeling approach and model fitting through an optimization process to overcome common indoor point cloud challenges, including noise, gap, and clutter. Kellner et al. (2023) developed a multi-step data-driven algorithm enriched with AI techniques for the 3D reconstruction of building models at Level of Development (LoD) 400. The proposed approach utilizes an AI semantic segmentation network to separate the following classes: doors, door leaves, windows, walls, ceilings, floors, and clutter. Subsequently, a 2D projection combined with a neighborhood graph structure is employed to partition 3D space within indoor environments, followed by applying the RANSAC plane fitting algorithm to reconstruct 3D models of walls. Ultimately, a bounding box is fitted to the points pertaining to each individual instance of door and window elements.

Staircase points detection and modeling

Staircase detection within point clouds and the subsequent creation of staircase DT models is an area of research that has received less attention compared to other applications of point cloud processing. Staircases exhibit diverse shapes and dimensions, and their visual representation can be influenced by different factors, such as structural design and the quality of the point cloud data. This complexity introduces challenges in developing robust and broadly applicable staircase detection algorithms. Additionally, utilizing ML approaches for staircase detection heavily relies on huge labeled datasets for network training purposes. The scarcity of such datasets specifically for staircases has impeded progress in research within this domain. Among the little research conducted on staircase point detection and digital model reconstruction, Schmittwilken et al. (2009) introduced a low-level module based on the random sample consensus (RANSAC) algorithm to generate planar polygonal patches for building facades and the surrounding ground. They employed Conditional Random Fields (CRFs) to classify patches into facade, window, door, and staircase classes, considering local neighborhood information and incorporating attribute grammar, including object partonomy and observable geometric constraints.

In 2009, Schmittwilken and Plümer (2009) proposed a top-down approach for reconstructing symmetric and partly recursive objects, such as a triple-run staircase from point cloud data. The proposed method utilizes an attribute grammar formulation using geometric dependencies for the design of 3D models and subsequently employs the random sample consensus paradigm for model selection and extraction of the geometric parameter of each 3D object. Sinha et al. (2014) presented a data-driven approach that employs a minimal 3D map representation and calculates step-like local features using point neighborhoods to detect staircase points. Yang et al. (2019) employed a bottom-up hierarchical semantic classification method, incorporating various semantic definitions, such as planarity of wall, ceiling, and floor surfaces at the geometric primitive level, to establish relationships between the staircase connection space and indoor space. For the coarse segmentation of staircase points, the height histogram of points is used to identify the void region between the planar surfaces of solid slabs and the connection space with staircases. Subsequently, the connected component algorithm is applied to cluster distinct pieces, planes, and clusters of staircases. Finally, the α-shapes algorithm is employed to construct the surface model for each step of the staircase.

In conclusion, the automatic creation of digital building twins using point cloud data is a research field constantly facing challenges such as complex space layouts, clutter, obstructions, and the need to provide methods for representing volumetric semantic models. The challenges become even more complex for elements such as staircases, which can have varying appearances based on their design. In the research presented in this paper, we aim to develop a hybrid bottom-up, top-down method for the automatic creation of a DT model for staircase structures using point cloud data. The proposed method leverages domain knowledge in construction and design to create para-

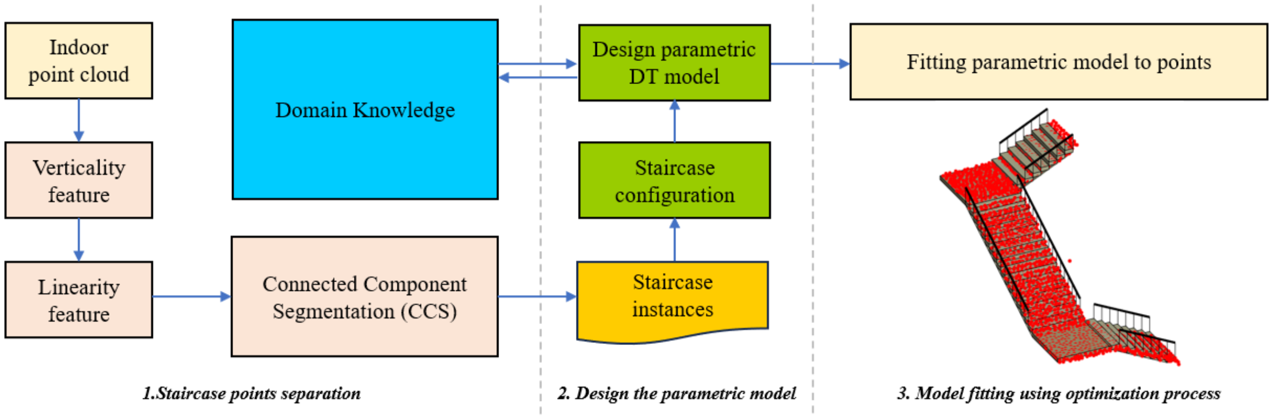

Figure 1: The proposed workflow for creating the DT model of the staircase.

metric models that can consider semantic relationships between components, allowing to overcome challenges such as noise and obstructions.

Methodology

As shown in Figure 1, the proposed workflow for the automatic creation of the DT model for staircase elements consists of three major steps, including 1) staircase points separation, 2) designing the parametric model of the staircase, and 3) model fitting using an optimization process. The details of the steps are given in the following subsections.

Staircase points separation

Staircase structures are typically inclined and constructed with a specific slope. Various factors, such as building regulations, architectural preferences, and the intended purpose of the staircases determine the inclination angle of a staircase. In residential and educational buildings, staircases are often designed with a relatively gentle incline to provide comfort and ease of use, such as for the convenience of (elderly) occupants. In the proposed method, the Verticality geometric feature is employed to distinguish inclined staircase points from other structural elements within the point cloud space, including vertically oriented walls and horizontally oriented ceilings and floors (Figure 2b).

To calculate the Verticality feature for each point in the point cloud space, the equation 1 is used with a neighborhood of 25 cm (Grilli et al., 2019). The selected neighborhood radius value ensure the presence of a minimum number of neighboring points for accurate estimation of Verticality features for the main structural elements, as well as small furniture objects.

$$Verticality = 1 - nz, \tag{1}$$

where nz is the normal vector value toward the Z axis, which is calculated by the covariance matrix and eigenvector values of the nearest neighboring points using equation 2 (Grilli et al., 2019):

$$c = \frac{1}{k}\sum_{i=1}^{n}(pi - \bar{p}).(pi - \bar{p})^{T}, \tag{2}$$

where k is the number of neighboring points, pi and p also refer to the 3D coordinates of the points being considered. Additionally, the eigenvalues and eigenvectors are determined by equation 3 where λ and $\vec{v}$ are eigenvalues and eigenvectors respectively (Grilli et al., 2019):

$$c.\vec{v}_j = \lambda_j.\vec{v}_j, \quad j \in \{0,1,2\} \tag{3}$$

Points associated with entirely horizontal elements are assigned a Verticality value of zero, while points pertaining to completely vertical elements are assigned a Verticality value of one. In this case, a confidence interval of 45%, characterized by approximate slopes ranging from 0.05% to 0.5%, is considered to extract the inclined points (Figure 2c).

The output of this process includes inclined staircase points, edge points of walls and ceilings, floor elements, noise points, and clutter. To extract points specific to each staircase instances, we adopt a two-step approach. Initially, the Linearity feature of the points is leveraged using equation 4 to eliminate the edge points of wall and ceiling elements (Figure 2e). Subsequently, the Connected Component Segmentation (CCS) algorithm is employed to segment points into distinct groups based on their connectivity, effectively isolating small segments that often appear as clutter within the point cloud space (Figure 2f) Trevor et al. (2013).

$$Linearity = \frac{\lambda_1 - \lambda_2}{\lambda_1} \tag{4}$$

As shown in Figure 3a, the extracted staircase lacks points corresponding to the horizontal planes of the staircase landing tread. This omission is due to the exclusion of horizontal points in the filtering process of the previous step. However, this information gap proves advantageous in subsequent steps for separating staircase components and their configuration analysis.

Design the parametric model of staircase

The structural configuration of interconnecting staircases between building levels frequently comprises multiple stair tread parts and incorporates two or more landing treads. The design and structural morphology of these staircases is inherently influenced by factors such as the flow of ingress and egress and the placement of landing treads. To quantify the number of landings and determine their direction, the central portion of the staircase points is examined using 3D point density analysis (Figure 3b). This analysis reveals that the extracted staircase element comprises three flows and two landing treads that run from left to right, top to down, and right to left, respectively (Figure 3c). This information serves as valuable input for subsequent steps, particularly within the parametric design of the staircase structure.

The staircase structure typically consists of distinct primary components such as step riser, step tread, railing etc. The differences between staircases primarily pertain to the number and dimensions of the primary components (e.g. number of steps, width, length, depth of steps, and landing treads) as well as the specific modes of flow rotation and positioning of the landing tread. Specifically, we consider four possible rotation types, denoted by numerical identifiers 1, 2, 3, and 4, corresponding to left-to-right, right-to-left, bottom-to-top, and top-to-bottom orientations, respectively (Figure 4a). For instance, the primary configuration of the extracted staircase is represented by the array ”142” (Figure 4b). This signifies that the staircase in question consists of three flows and two landing treads, each being successively positioned from left to right, top to bottom, and right to left. Consequently, a library of parametric models is systematically generated based on the number of landing treads and flow patterns.

Model fitting using optimization process

The designed parametric model has low geometric accuracy but a consistent semantic topology. To determine the optimal geometric values of the DT model's components, the optimization process is used to fit the designed parametric model to the extracted staircase points. The Nelder-Mead optimization algorithm fits the initial parametric model to points (Nelder and Mead, 1965). Within this context, the objective function employed during the model-to-point fitting process is defined as follows (5) :

$$Obj = min(G + \frac{F}{10}) \tag{5}$$

The term G refers to the distance between the points and the step planes, which is a critical factor for the vertical alignment of the parametric model toward the staircase points (6) (Figure 5):

$$G = \sum_{i=1,j=1}^{n,k} |p_i - plane_j| \tag{6}$$

where the p_i is the staircase point i, $plane_j$ is the jth plane of parametric model, p_{stairs} is the number staircase points

and p_{in} is the number staircase points inside the step box of staircase model.

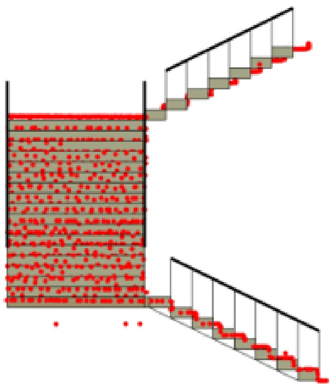

Figure 5: Fitting parametric model of staircase to points; Vertical alignment of the parametric model toward the staircase points (term G).

The term F is related to the number of steps present within each flow connecting the landing treads, as well as the placement of the parametric model planes on the staircase points on the X-Y plane (7) (Figure 6):

$$F = |p_{stairs} - \sum_{i=1}^{steps} p_{in}| \tag{7}$$

where the p_{stairs} is the number of staircase points and p_{in} is the number of staircase points inside the step box of the staircase model. To enhance the process of fitting a model to the points, in each iteration, the 3D points inside each box of the model are extracted and used in the optimization process. This includes the points on the landing treads that were omited during the staircase points separation step.

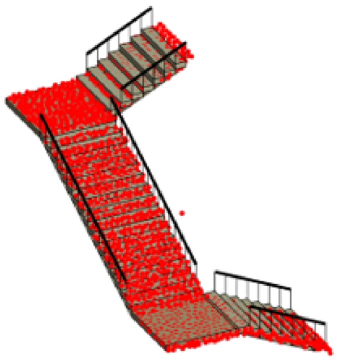

Figure 6: Fitting parametric model of staircase to points; placement of the parametric model planes on the staircase points (term F).

During the model fitting process, the points inside each box of the DT models are extracted and appended to the previously extracted staircase points to improve the model fitting, specifically in the parts of landing treads. In between, adding excessive steps may not change the overall distance value between the staircase points and the model planes. To address this challenge, a penalty factor is incorporated into the objective function. Specifically, if an additional step does not encompass any points within the 2D X-Y plane, a penalty value of 10000 is appended to the final value of the objective function (8):

$$if\, p_{in} == 0 \;\; then \;\; Obj = min(G + \frac{F}{10}) + 10000 \tag{8}$$

Result

To evaluate the proposed method, the dense point cloud dataset is used that has been captured by the authors at the City campus of the Technical University of Munich (TUM). The TUM building in question (Building 1) is a multi-story structure comprising four floors. The point cloud data was captured using NavVis laser scanner with a spatial resolution of 0.1 cm (https://www.navvis.com/). Figure 7 illustrates an overview of the data.

Figure 7: Overview of the TUM Building 1 data.

Experimental results on staircase points separation

To extract the staircase points within each floor's point cloud, first, the Verticality feature is calculated for the points in each floor by considering the neighborhood radius of 0.25 cm. Next, the inclined points of staircases are extracted from the point cloud space considering a confidence interval of 45%, which encompasses the points with the Verticality feature between 0.05 to 0.5. As mentioned in Section 2, the result of this step contains noise and clutter. In this regard, the linearity feature is calculated for each point considering the neighborhood radius of 0.50 cm to detect the noise and boundary points between the ceiling, floor, and wall elements. Finally, the CCS method is employed to segment the points belonging to each staircase instance. In this case, the distance threshold for connecting the points in each segment is considered as 25 cm and the minimum number of points to segment each staircase instance is specified equal to 5000. Figure 8 shows the result of staircase point separation for different floors of the TUM Building 1 dataset.

To assess the effectiveness of the staircase points separation step, the manually annotated point cloud and the extracted staircase points are compared, and the results are reported in Table 3 based on Equations (9-11). In this regard, an overall accuracy of about 95% for separating staircase points from other elements in the point cloud space highlights the performance of the proposed workflow for separating staircase points, which significantly influences the quality of the model fitting steps.

$$Precision = \frac{TP}{TP+FP} \tag{9}$$

$$Recall = \frac{TP}{TP+FN} \tag{10}$$

$$F\text{-}score = 2.\frac{Precision.Recall}{Precision+Recall} \tag{11}$$

Experimental results on creation parametric model of staircase

First, the central parts of the extracted staircase points are examined to design the parametric DT model for the extracted staircase instances. In this regard, the structure of staircase instances in the point cloud of the second to third floor is determined by array 142. This means the corresponding staircase structure consists of two landing treads and three flows formed from left to right, up to down, and right to left, respectively. Also, the staircase structure extracted in the point cloud floor fourth is determined by array 32, meaning that this staircase consists of one landing tread element and two flows, which are formed from bottom to top and from right to left.

Subsequently, parametric DT models are designed based

Table 1: Accuracy evaluation of staircase points separation.

Dataset	F (2)	F (3)	F (4)
Precision	0.75	0.60	0.70
Recall	0.80	0.73	0.85
F-Score	0.77	0.64	0.75
Overall accuracy = 0.95			

on the provided information for each staircase instance. These models incorporate various parameters and consider their relation, including the number of steps between landing treads and dimensional values of geometric properties such as width, depth, and height, which, in addition to maintaining the semantic relation between the staircase components, also promotes geometric integrity. Following this, the designed parametric models are fitted to the extracted staircase points to estimate optimal values for the parameters of the created DT models. As discussed earlier, the Nelder-Mead optimization method and the objective function are employed to fit the model to the points and extract optimal parameters for the designed DT models, ensuring that the models closely resemble real-world structures.

(b)

(c)

Figure 9: The result of staircase points separation for TUM Building 1 dataset: (a) floor-2, (b) floor-3, and (c) floor-4.

To evaluate the proposed method for the automatic creation of the staircase DT model, the differences between distances and dimensional values of the staircase components in the reference DT models and the generated models are calculated. For each dataset, the standard metric of mean error is presented in Table 4. Furthermore, the distance between the model and the extracted staircase points is measured for each dataset, indicating the closeness of the created model to the captured point cloud. The overall mean accuracy of about 0.04 m highlights the performance and effectiveness of the proposed method for the automatic creation of DT models for staircase structures in the built environment.

Table 2: Accuracy evaluation of staircase DT creation.

Dataset	F (2)	F (3)	F (4)

Points to Model	0.08	0.11	0.07

Conclusion

This research presents a novel hybrid bottom-up, top-down method to create the highly parameterized DT model of a staircase structure. The proposed method aligns existing knowledge in the design and construction of building elements with the parametric modeling framework, allowing us to consider different degrees of freedom to model a wide range of staircase models in the real world. By considering semantic relationships between staircase components, the presented approach provides solutions to overcome challenges such as point cloud obstruction, noise, and complexity in the representation of 3D geometric models. In this regard, an overall mean error of about 0.04 m in creating a highly parameterized DT model for a staircase structure with different shapes and designs promises significant progress in the field of "Scan-to-BIM" that ultimately provides high-quality DTs with rich semantics and coherent geometry. Despite diligent considerations, the proposed method has inherent limitations in creating digital models of round staircases with non-Manhattan designs, which will be addressed in future works.

Acknowledgments

The research presented has been performed in the frame of the project AI4TWINNING (Artificial Intelligence for the automated creation of multi-scale digital twins of the built world) funded by the TUM Georg Nemetschek Institute Artificial Intelligence for the Built World (GNI).

AUTOMATING AS-BUILT-MODELLING BY USING DELIVERY DOCUMENTS

[3]comstruct ICT GmbH, Munich, Germany

Abstract

Building Information Modeling (BIM) promises advantages for Facility Management (FM) by integrating the lifecycle phases of a building. Especially the optimized start-up phase is mentioned as one key advantage of the BIM method. In order to implement a successful start-up, a holistic as-built model is necessary, in which all relevant information for FM is stored. Actually, for the generation of an as-built model a high manual effort is necessary. This paper aims to develop an automated as-built model by using delivery documents. Therefore, this paper presents a process using Optical Character Recognition and analyze the process in a proof-of-concept.

Introduction

Building Information Modeling (BIM) aims to integrate all stakeholders by using a digital building model throughout the lifecycle (Borrmann et al. 2021). The focus here is particularly on the consistent exchange of information using open data exchange formats (Baranova 2021). One important standard to exchange data throughout the lifecycle is the Standard of the Industry Foundation Classes (IFC) (ISO 16739-1). Especially IFC-based as-built models could support an efficient information exchange between BIM systems and FM systems, as Computer Aided Facility Management (Matarneh et al. 2019; Ensafi et al. 2022).

As-built models hereby describes the actual state of the building, as it is constructed and commissioned (Bartels 2020). It represents the update of the as-planned model, which describes the target status of the building and includes graphical and alphanumerical data (Pilling 2016). By integrating all FM-relevant data and the data of the service provisioning during the Operations & Maintenance (O&M) phase, an As-Operated model is generated (RealFM 2021). The maturity of the models is shown in Figure 1.

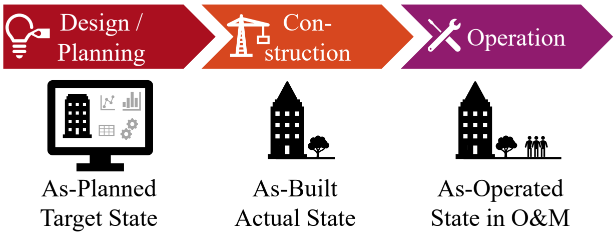

Figure 1: Maturity Levels of the BIM models throughout the lifecycle

While as-planned states the status of the design phase, the as-built modelling requires a finer level of detail, a more precise modelling as well as an accurate data import and maintenance (Pătrăucean et al. 2015). But these data is often poorly collected, processed and revised in practice, what especially applies to asset-specific engineering data (Asmar et al. 2022; Hellenborn et al. 2023). This is especially due to the manual data entry during the construction and commissioning phase and the need for manual verification of Facility Managers (Klein et al. 2012).

1. In order to define the necessary data in the as-built model, it is necessary to unambiguously and clearly define the owner requirements, specially through exchange information requirements (EIR) and Asset Information Requirements (AIR). Research studies show, that the client's requirements are often not clear and specified (Hellenborn et al. 2023). Furthermore, the requirements change from client to client (Di Filippo et al. 2021).
2. In addition to that, especially for Construction Managers the usage of BIM software tools is often not common. Actually, the Construction Managers are using specific tools, such as MS Project or ERP to manage their processes as well as MS Office products, such as Word or Excel. This particularly applies to medium-sized companies (Lauer 2021).
3. The needed information is stored in documents, which are handed over in paper form or as a digital file. In particular, smaller craft businesses that work as subcontractors hand over their documents in paper form, which leads to a high documentation effort (Hausmann et al. 2022).

Actually, there is no connection between the delivery documents and the revision documents with the digital building model, although all needed information is stored in these two documents. Various studies focused on the processing of geometry to develop an as-built model (e.g. (Klein et al. 2012)) or on the documentation of construction specifics, such as timetables (e.g. (Park und Cai 2017)). The needed information for the asset owner and Facility Management are mostly not taken into account. Especially the information is not automatically read out of documents and assigned to objects in the model.

Therefore, it is necessary to implement an IFC-based interface, that enables the construction managers and their companies to automatically fill in all relevant data on the objects in the digital building model. By developing such an interface, the modelling of as-built models could be highly improved.

Based on this, the Facility Management is able to transfer and use all data in their Computer Aided Facility Management (CAFM) systems. This would lead to a better understanding of the building and improvements of efficiency by the FM as well as an increasement of user satisfaction (Bartels 2020).

Literature Review

Existing Solutions

In order to evaluate the state-of-the-art of as-built models, existing solutions for data acquisition, data integration, and data visualization need to be analyzed.
In recent years, various solutions for data acquisition for as-built models have been published. The earliest presented solutions are based on 3D laser scanning for building or geotechnical sites in order to generate geometric as-built models (Su et al. 2006; Deruyter et al.). Based on that research, further solutions for the acquisition of geometric data use advanced technologies, such as Autonomous Unmanned Aerial Vehicles, Imaging technologies or Augmented Reality were published (Omar und Nehdi 2016; Freimuth und König 2019). Not only geometrical but also alphanumeric data was integrated in as-built models, such as construction dates or production data (Son et al. 2017; Son et al. 2015). The analysis of these case studies shows, that the processes are regularly done manually. One presented solution for automated as-built models are sensors (Moselhi et al. 2020).
For data integration the solutions can be divided in solutions that (1) use proprietary exchange formats and (2) that use the open exchange format of the Industry Foundation Classes (IFC). Moretti et al 2020 use IfcSharedFacilitiesElements for the integration of as-built data (Moretti et al. 2020). Also solutions for as-built-schedules are presented by using an integrated entity information model based on ID of attributes (Fagiar et al. 2023).
For data visualization especially site photography is mentioned. Therefore, workflows were developed to efficient processing of unordered photos (Jadidi et al. 2015). This case study as well as the majority of the other case studies emphasizes that humans need to be trained and that humans are a central part for generating as-built models successfully. Furthermore, the analysis shows, that especially the geometric aspect is in the foreground.

Interoperability and Data Exchange standardization

This case study focusses on open exchange standards. Therefore, it is necessary to analyze the Model View Definitions (MVD) that are defined in the IFC standard. Furthermore, the state of the art of the Information Delivery Specifications (IDS) need the be analyzed.
The MVD is used to define a subset of the IFC data and defines exchange requirements (buildingSMART international 2024b). An IDS is a document, that can be interpretated by a computer and defines how information are delivered in a project. It hereby combines IFC and other extensions, such as company specific properties or properties of the buildingSMART Data Dictionary (buildingSMART international 2024a). While the concept of MVD deals with the content that is relevant for software manufacturers (e.g. mapping the class hierarchy and the transfer of geometry) and is the basis for use-case based Software Certification, the concept of IDS defines the alphanumeric information content of models and is therefore the more relevant concept for users and as-built models, because it describes all data that is needed.
One important definition for the handover to FM and therefore for as-built modeling are the FM-Handover-Aquarium and the FM Basic Handover, that is defined as MVD in IFC 2x3. The MVD aims to define the handover of information from Design and Construction Phase to FM software, such as CAFM and CMMS (buildingSMART international). The MVD are based are based on the entities and Property Sets (PSet) in IFC.
IFC is a central data format for IDS related to FM. Although there is currently no separate FM domain in IFC 4.3 (this still existed in IFC 2x3), the entities, such as

- Shared Facilities Elements – IfcInventory, IfcFurniture, IfcAsset and IfcOccupant
- Shared Management Elements – IfcActionRequest, IfcOccupent, IfcOrderAction, IfcProjectOrder, IfcPermit, IfcCost, IfcCostSchedule, IfcWorkCalendar, IfcWorkPlan, IfcTask and IfcEvent.

and Property Sets, such as, PSet_ProjectOrderMaintenance-WorkOrder, PSet_Utility, PSet_Warranty or PSet_ActionRequest are integrated for FM in IFC. There are also other class-specific PSets, quantity sets and other attributes relevant to FM. The classes defined in IFC are particularly suitable for describing as-built data. These can be used to fundamentally describe the building and the associated technical systems. There are also individual classes that can map FM process data (Bartels 2020; Bartels und Wimmer 2024).

Methodology

In order to implement an interface that allows an automated filling of the missing attributes from the as-planned state to the as-built state by taking IFC and IDS into account, four steps were taken. These steps are shown in Figure 2.

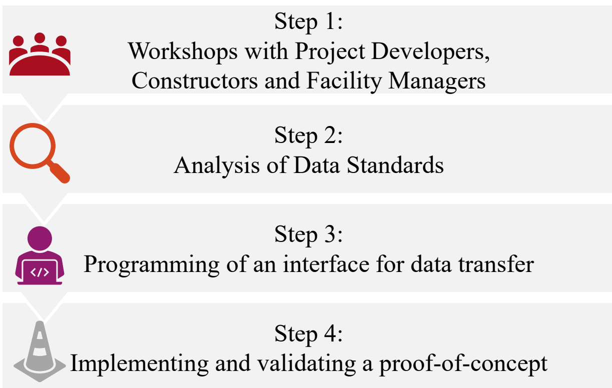

Figure 2: Methodology of this paper

First, workshops were conducted with Developers, Constructors, Planners and Facility Managers in order to get to know the needed attributes and the state-of-the-art. Secondly, data standards were analyzed to develop data specifications, with whom it is possible to filter the needed data out of documents and to transfer the needed data into an IFC-file by applying IDS. Thirdly, an interface was programmed and implemented to transfer the files.

Fourth, the programming and the process was implemented in a proof-of-concept to validate the programming, its acceptance and to analyze the results.

Data Analysis

Evaluation of the basis for information exchange

To implement an interface for transferring data and information from delivery and revisional documents to the digital building model by using IFC, the Exchange Information Requirements and Asset Information Requirements were evaluated with workshops.

Therefore, all in all 9 workshops were conducted, respectively 3 workshops with project developers and owners, 3 workshops with construction companies and 3 workshops with FM companies. The workshops took place from June 2023 to September 2023 and were conducted in person as well as online.

The workshops showed, that as-built models are more and more requested in building projects. In most of the cases, IFC is asked as exchange format for as-built models. But also proprietary formats (especially Revit) are requested.

Furthermore, the workshops showed, that there is a need for the automated reading and transferring of information out of delivery and revisional documents to the digital building model. Especially the project developers stated, that this would improve the information exchange across the whole lifecycle and would perfectly fit to their aim of having as-built data for all developed building. For the Construction companies, the linking of documents and the digital building model also offers opportunities and is viewed positively; in addition, the aspect of a possible tracking of deliveries and thus a should-is comparison is emphasized as an advantage.

Lastly, the workshops aimed to evaluate the needed information of the stakeholders. The project developers stated, that the EIR and AIR are still not finalized and change slightly in the projects. The same effects are stated by the construction and FM companies. This often causes incomplete or wrong information in the as-built models due to missing definitions of the EIR and AIR in contracts. Therefore, some of the construction and FM companies developed their own AIR and EIR. Although the AIR and EIR vary slightly, the experts stated, that the information requirements are usually based on the Construction-Operations Building information exchange (COBie) or the German standard CAFM-Connect (CC). Especially CC is used in most of the projects as basis for the Information Requirements. An analysis of these exchange formats is shown in the next section.

Relevant Exchange formats

Due to its complexity, IFC is not specific and fully suitable transferring and storing FM data throughout the lifecycle of a building (Yalcinkaya und Singh 2019). Therefore, formats have been developed to transfer FM data properly and to get as-built models. As shown in the next section, the IFC-based exchange formats CAFM-Connect and COBie are the most mentioned formats for the delivery of as-built models. The workshops showed, that the EIR and AIR are based on the attributes mentioned in these two standards.

COBie was developed in 2007 by Bill East form the United States Army Corps of Engineers (Lavy et al. 2019). The format uses spreadsheets to transfer BIM information from the Design and Construction process to FM (FM Handover). COBie defines three types of information delivery, one for information, that is created by designers, one that is created by contractors and one that is created by both of them. Hereby COBie defines information requirements for spatial and equipment assets (East 2013).

CAFM Connect is a German IFC-based initiative of various CAFM vendors. CC aims to capture the data collected in the Design and Planning phase and transfer it in a usable way into CAFM systems (Verband für die Digitalisierung im Immobilienbetrieb, CAFM RING e. V. 2019). Therefore, various lists were developed, to define all relevant data for the building objects, e. g. based on the German standard DIN 276 (Otto und Bartels 2018).

In the following, a door will be used as example for the requested data in CC. IFC defines a door with the entity IfcDoor, a subtype of IfcProduct. Various Property Sets assign to the entity IfcDoor, such as PSet_IfcDoorCommon, PSet_DoorLiningProperty. But also FM-data could be assigned by using PSet_Warranty, PSet_Manufacturer or PSet_MaintenanceStrategy (buildingSMART international 2022). These attributes are the basis for CAFM Connect and further defined in the lists. An example for the standardized attributes of a door (IfcElement IfcDoor) is shown in Table 1.

Table 1: Example of CAFM-Connect Attributes (ifcDoor)

IfcElement	DIN 276	Attribute	Type
IfcDoor	334.10	Door Stop	IfcText
IfcDoor	334.10	Number of wings	IfcText
IfcDoor	334.10	Automatic drive	Ifc Boolean
IfcDoor	334.10	Year of manufacture	IfcReal
IfcDoor	334.10	Description	IfcText
IfcDoor	334.10	DiBT approval number	IfcReal
IfcDoor	334.10	Hold-open system	IfcText
IfcDoor	334.10	Fire resistance class	IfcText
IfcDoor	334.10	Escape door	Ifc Boolean
IfcDoor	334.10	Manufacturer	IfcText
IfcDoor	334.10	Emergency exit lock	Ifc Boolean
IfcDoor	334.10	Overhead door closer	Ifc Boolean
IfcDoor	334.10	Opening type	IfcText
IfcDoor	334.10	Protection requirement	IfcText

Furthermore, CAFM Connect developed so called BIM profiles, in which relevant attribute for FM services are defined (Verband für die Digitalisierung im Immobilienbetrieb, CAFM RING e. V. 2023).

Development of an attribute list and process

Based on these data exchange formats, a consolidated list of attributes for building objects has been developed. The following Figure 3 shows the attributes of a door, all based on the global unique identifier (GUID), as example and in which phase data is actually included in the model. It furthermore shows, that various stakeholders need to enter data throughout the lifecycle. At the beginning of the project, the planners (e.g., Architects) enter various planning data. These data are needed for tendering and awarding.

Maturity Level	Source of Information	Attributes / Information
As-Planned	Digital Building Model / Door List (BIM-Software) *Planner (here: Architect)*	GUID Name Description Emergency Exit lock Protection Requirements Number of wings Opening Type Overhead door closer Fire resistance class Emergency Exit Fire Protection Door Stop Hold-open system
As-Built	Delivery Note *Construction Manager*	Manufacturer Year of Construction Serial number Automatic drive DiBT approval number
	Revision Documents *Construction Manager / Commissioning Manager*	Inspection intervall Maintenance intervall Commissioning date Qualification of the examiner
As-Operated	Contract *Facility Manager*	Contracter Fault Priority
	Service Provisioning Documentation (CAFM) *Facility Manager*	Inspection Report Result Description Responsible Person Date of Maintenance Next Maintenance Result *plus* *Building Automation System and IoT-Data*

Figure 3: Data entry throughout the lifecycle

Based on that data, the Constructor execute his services. Due to the incomplete data and changes in the construction phase, it is necessary to enter further data. During the construction phase, the Construction Manager need to enter various data to achieve an as-built model. Especially data about the manufacturer and the year of Construction as well as serial numbers need to be entered in the digital building model. Beside that data also data of the commissioning is needed to receive an as-built model. Therefore, after the Commissioning additional data need to be entered in the digital building model. These data are especially Commissioning Dates and data about the service provisioning for Facility Management.

The remaining data is entered during the O&M phase of the building by the Facility Management and includes data about the service provisioning. These data could be transferred out of the CAFM system by using IFC.

Especially the data, that need to be entered by the Constructors is a key success criterion. On the other hand, that data is often not fully entered in the digital building model. The workshops with the constructors showed, that the Construction Manager is not capable to enter all relevant data due to

1. a lack of knowledge regarding BIM, especially in entering data
2. an insufficient hard- and software equipment on the construction site,
3. especially a lack of time due to the task on the construction site
4. belayed information of the sub-contractors due to missing documents.

The numbers 1-3 could be solved by the suggested approach of this paper. Furthermore, number 4 could also be solved, if the delivery of the documents is ruled in the contracts and the delivery of documents could even better be controlled.

Development of an automated document-based as-built model

Based on the data standards and processes, an automated exchange process to receive an as-built model has been developed.

Extraction of information on delivery documents

Currently the technical capabilities of material suppliers vary substantially. Around 1 percent of suppliers can share delivery bills via an API with defined End Points that can be accessed from external parties. Approximately 5 percent of material suppliers offer customer portals, where they upload electronically generated PDFs . The majority of suppliers, around 74%, are able to send scans or electronically generated PDFs of the delivery bills to an agreed upon mailing address. Only 20% of suppliers are not able to electronically transfer the delivery receipt. The only way for them to transmit the information is to bring the physical document to the construction site or send it via post. To mitigate this problem and enable all delivery receipts to be pushed into the digital workflow a scanning application on the construction site is unavoidable.

After each document is at least available as a digital picture the next step is to retrieve the information of the scanned documents. This can already be done with common OCR applications (to transform the scan into a machine-readable string. (Memon et al. 2020; Chaudhuri et al. 2017) After all documents are in machine-readable format the varying formats need to be mapped on one central standard. To guarantee a very high data quality this mapping is currently still done manually but large language models already show to be a great way to automate this task. An extract of a delivery bill of the example project is shown in Figure 4.

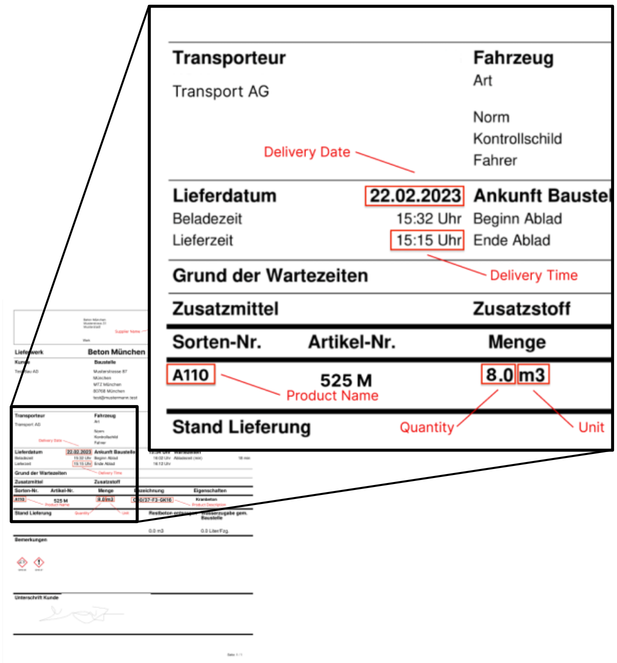

Figure 4: Extract of the exemplary delivery bill

IFC integration – Developing a process of automated as-built-documentation

The process of automatic as-built documentation on the IFC model is represented by a two-track, interlinked workflow between the construction site ("on-site") and the material dispatcher ("off-site") and is shown in Figure 5. As in the conventional workflow, the construction site is the starting point: The site manager or foreman determines the time of a material delivery. For this purpose, a task is created in a model-based construction management software, which consists of the following information: (1) time of delivery (date and time), (2) location of delivery (linked components or GUIDs), (3) product specifications (e.g., compressive strength of the concrete), and the (4) order quantity (e.g., m^3 of the delivery). While information (1) and (2) is entered individually by the ordering party, (3) can be read from the stored IFC file and thus pre-filled for the order. The construction site management would then only have to send the order information in the next step after checking the order. The order information, including the linked GUID(s), is then automatically sent via an interface (API) to the ERP system of the dispatcher, who checks the incoming order electronically and releases and picks the goods accordingly. After the final check, the physical delivery process can be started while the information flows back into the construction site management software via the updated delivery information in the ERP system. This means that the status of the delivery is visible at all times, as well as the expected time of arrival (ETA) and the underlying material information. When the delivery finally arrives and all materials have been delivered as ordered, the delivered and thus installed material information must be integrated back into the building model. There are two possible ways of doing this: using ML, as described in the section before, or sending delivery bills electronically. If the information contained in the delivery bill cannot be transferred from the dispatcher's ERP system to the construction site management software via the interface, the delivery bill would have to be scanned manually on site. The use of ML allows the automatic capture and evaluation of the information depicted on the delivery bill and thus the transfer into a digital format. By matching the previously placed digital order and uploading the delivery bill, the delivery bill can be subsequently linked to the order and thus to the underlying GUIDs. Ideally, however, the use of a paper-based delivery bill should be avoided anyway.

In this case, the delivery bill would be sent digitally via API when the physical materials are dispatched. The previously placed order is linked to the components, making it easy for the construction site team to compare them when goods are received for verification purposes.

Once the information on the delivery bills has been successfully processed electronically, the semantic interoperability of the collected information is permanently guaranteed. This is due to the storage of the information in a model-based and document-oriented NoSQL database management system. Although this database system is initially independent of the IFC standard, the export of the data from the software allows it to be converted into a wide variety of formats. Both API requests and the export as an IFC file itself access the database and convert it into the desired format with respective PSets.

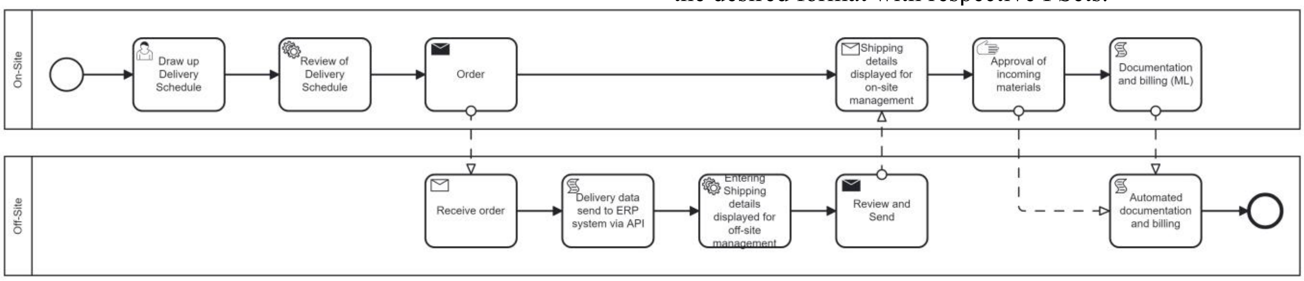

Figure 5: Process of integrating information in BIM

Critical reflection on surplus value

The process of automatic as-built documentation on the basis of model-based deliveries provides great added value, particularly for users on the construction site, but also for all other project stakeholders. The results show, that a majority of the demanded information (see previous chapters) could be filled in automatically by using OCR in combination with BIM.

The proof-of-concept also shows, that the added value arises primarily in the following four areas for the construction site: (1) order information, (2) communication, (3) documentation and (4) archiving.

Firstly, material information already contained in the model does not have to be entered again when filling in the order information. Instead, the quality and quantity can be pre-filled and only needs to be checked before the order is placed. In shell construction in particular, where measurements are still taken using analog, laborious and error-prone processes based on 2D plans, time savings of over 60% (equivalent to around 2 minutes per order) can be achieved for a typical order. Whereas previously, for example, the length, width and height of foundations were multiplied and then added together by number, the site team now obtains this information by simply clicking on the components.

Secondly, the information can subsequently be transmitted electronically via an interface to the dispatcher's ERP system. This process eliminates the need to prepare the order information again (e.g., as a PDF for sending by e-mail) or to call the material supplier. As a result, time savings of around 80% (equivalent to around 1 minutes per order) can be observed.

However, the greatest added value for the construction site comes from automated documentation. Today, manual diaries ("delivery lists"), for example in the form of an Excel spreadsheet, are created at great expense, particularly for concrete but also steel deliveries. Almost all the information typically contained there, such as the installation date, the delivery bill number, the quantity, the component or the location, could be automated using the process outlined above. What would currently require time-consuming updating could be generated and pre-filled at the touch of a button, leaving just one verification process. Time savings of over 90% (equivalent to approx. 3 minutes per order) seem plausible.

Finally, the filing of delivery bills in physical orders or the filing of scanned or digitally transmitted delivery bills in digital folders is also overdue. Delivery bills would be automatically linked to the IFC model and made available to everyone at any time via an interface to Common Data Environments or billing software, without the need for manual intervention. Time savings of almost 100% (equivalent to approx. 1 minutes per order) can therefore be realized.

For the construction site team alone, this results in a time saving of 7 minutes per order and documentation process. For a medium-sized construction project (roughly 5 Mio EUR construction volume) with approx. 300 delivery bills per months, resulting in roughly 10,000 orders, this would mean 1,170 hours in total. Additional time and cost savings can be expected from the reduction in human error when planning and rescheduling orders, as well as from automatic version management and the resulting traceability of changes. Finally, there are possibilities for data analysis and evaluation, e.g., with regard to target/actual materials or CO_2 values, which were previously unheard of or only possible with great effort, if a material database is connected accordingly.

Conclusion

This paper presented an automated approach to generate as-built models by using the BIM method in combination with OCR. It hereby combines an IFC-based model with information out of delivery documents. A process has been developed and implemented in a proof-of-concept.

By doing so, the efficiency of the information exchange and maintenance has been increased in the proof-of-concept. Furthermore, the automated exchange of information – based on IFC – lead to a more precise delivery of the information, that were evaluated in the workshops with project developers and facility managers.

This paper is a first approach for automated as-built models, that was evaluated in practice. the PoC shows that the process outlined in this paper can be used to automate data enrichment from BIM models to as-built models, further research is needed. The PoC shows in particular, that not all relevant information for FM could be extracted of the delivery documents. That means, that further documents – especially the revisional documents – need to be integrated in the process. In addition to that, the workshops with the experts showed, that not all companies are using digital delivery documents, but some still have delivery bills in paper form. This makes it necessary to scan or photograph the delivery documents. One solution is to use other internal systems (such as ERP).

All in all, this paper shows, that the manual integration of information could be reduced to a minimum by using OCR or related systems. Furthermore, it shows, that all relevant software systems, such as ERP-systems, need to be connected to the digital building model in order to fill in information automatically. Furthermore, PSets for IFC should be developed to generate as-built models out of delivery bills.

MODELING AND ANALYSIS OF JOINT WORK PACKAGE SIZING AND PROJECT SCHEDULING CONSIDERING RESOURCE CONSTRAINTS

Nianmin Zhang[1] and Xiao Li[1]
[1]Department of Civil Engineering, The University of Hong Kong SAR, China

Abstract

Effective work package sizing and project scheduling are essential problems in construction project management. In current studies, they are often treated as separate optimization problems. However, in practical situations where resources are limited, there is a growing recognition of the need to integrate these two processes to achieve more efficient and effective project management. This research aims to fill this gap by developing an integer non-linear programming model incorporating work package sizing and project scheduling while considering resource limitations. To evaluate the effectiveness of our model, we utilized Gurobi optimization software to solve nine project instances obtained from RanGen, each characterized by its unique complexities. Furthermore, we analyzed the impact of resource utilization on work package sizing and the project schedule, and we found that both excessive and inadequate resource availability can increase project costs.

Introduction

Effective project scheduling is a crucial problem in project management, as highlighted by several studies (Li et al., 2018; Tsz Wai et al., 2023). This problem becomes even more challenging in a resource-constrained environment, where project tasks exhibit interdependencies in two key aspects. Firstly, tasks compete for limited resources, and sufficient availability of resources is essential for initiating and executing construction tasks. Secondly, the project workflow imposes precedence constraints, whereby certain tasks must be performed based on the completion of specific scheduled tasks. These two interdependencies are encompassed within the resource-constrained project scheduling problem (RCPSP), which is widely recognized and formalized in the project scheduling literature (Hartmann and Briskorn, 2022).

From a perspective of scheduling scope and complexity, RCPSP can be categorized into two groups. The first group is the resource-constrained single project scheduling problem (RCSPSP), which aims to optimize the schedule and resource allocation for a single project to ensure timely project completion. In RCSPSP, the scheduling process is task-based, and each task to be scheduled has specified work content, such as processing duration and resource requirement, as well as an execution scope, such as precedence relationships among tasks. The second group is the resource-constrained multiple project scheduling problem (RCMPSP), which involves coordinating and prioritizing schedules across multiple projects that share common resources. The objective is to balance the workload across projects, ensure the timely completion of each individual project, and achieve the overall goals of the project portfolio (Issa and Tu, 2020).

With the implementation of the work breakdown structure (WBS) method in the construction industry, the RCPSP for construction projects has evolved into a work package-based scheduling problem, which can be considered as a complex extension of the RCPSP (Li et al., 2022). For example, the production of a modular room can be decomposed hierarchically into six work packages, including structure production, door/window production, wall production, print, electric service, and test, using WBS tools for planning or scheduling (Liu et al., 2023). Each work package typically consists of one or more elemental tasks that are not further decomposed (Li and Hall, 2019). Specifically, the work package for structure production may include elemental tasks such as board production, 2D assembly, and concrete curing. Therefore, in construction projects, not only should the resource and precedence constraints be considered in the RCPSP, but the size of the work package also has a significant impact on project performance. Specifically, smaller work packages tend to increase project complexity and workload while diminishing economies of scale. Conversely, larger work packages require a higher allocation of resources, potentially straining resource availability and leading to bottlenecks or delays. Furthermore, as demonstrated by Blazewicz et al. (1983), the RCPSP belongs to the category of strongly NP-hard problems, presenting a significant challenge in obtaining the optimal solution for RCPSP and acting as a bottleneck for further improvements in project performance. By considering a more comprehensive set of influential factors in the RCPSP, there is potential to enhance project management capabilities and improve the efficiency of resource utilization.

Work package sizing has garnered considerable attention, with studies demonstrating the significance of optimizing work package size to reduce project costs (Li and Hall, 2019; Li et al., 2021b). This optimization encompasses various factors, including minimizing costs associated with inaccurate estimation, monitoring, and control of work packages. Moreover, the sizing of work packages has implications for the project's economies of scale and discounted cash flow, further emphasizing the importance of this optimization in cost reduction endeavors (Liu et al., 2023).

While the optimization of work package sizing has enabled a trade-off among multiple objectives, there are still limitations in current studies that hinder the improvement of project performance. One limitation is that the work package sizing process often takes place during the initial planning stage of a construction project, without considering detailed task information such as task durations, resource requirements, and precedence relations among tasks (Li et al., 2023). However, resource constraints are common in construction projects and significantly impact the feasibility and effectiveness of work packages (Li et al., 2021a). This can lead to the creation of unsatisfactory project schedules during the project scheduling stage, ultimately resulting in poor project performance. Moreover, the work packages in RCPSP are predetermined and do not allow for splitting or recombination, limiting the flexibility of project managers to schedule work packages and effectively utilize resources in the project scheduling stage (Du et al., 2021).

To summarize, work package sizing and construction project scheduling are interdependent activities that should be considered simultaneously to mitigate project delays, cost overruns, and disruptions, particularly in resource-constrained and uncertain project scenarios. Work package sizing involves grouping tasks into cohesive work packages, which determine the resource requirements and processing time. These factors then influence scheduling decisions and the overall project cost. Project scheduling decisions, in turn, have a significant impact on resource availability, which affects the feasibility of work package splitting and recombination (Pellerin et al., 2020). By integrating work package sizing and project scheduling, project stakeholders can better manage resources, optimize project timelines, and mitigate potential bottlenecks or resource conflicts (Zaman et al., 2021).

However, most studies treat work package sizing and project scheduling as separate problems, neglecting the interrelationship between them in resource-constrained construction projects. To the best of our knowledge, no research to date provides an integrated resource-constrained project scheduling and work package sizing method while considering the interrelationship between them. Therefore, it is crucial to propose a new integrated method that combines work package sizing and project scheduling under resource and precedence constraints to reduce project costs while improving resource efficiency (Zhang et al., 2024).

To address the existing research gap, we present a joint model for project scheduling and work package sizing that takes into account both precedence and resource constraints. Our proposed approach makes the following contributions: 1) For the first time, we introduce an integrated model that considers the interplay between project scheduling and work package sizing. 2) To validate the effectiveness of our model, we conducted various experiments using Gurobi with nine project instances obtained from RanGen. 3) We analyze the impact of resources on project schedule and work package size by changing availability.

Methodology

Assumptions

- We assume that the project has been planned into a given set of tasks that are elemental. That is, no further breakdown of those tasks is possible for reasons that may be technical, logistical, financial, administrative, or cultural.
- Only the active tasks can be grouped into a work package due to the specific role in the construction project.
- Considering the mass production in real scenarios (e.g., reduction in set-up time, material preparation, mass workforce, and new production tech), lag time is considered among tasks that are grouped into the same package, while the package-to-package is still regarded to be hard precedence-constrained.

Problem Modeling

Consider an task-on-node (TON) project network described by $G(N,A,W)$, where N denotes a set of tasks in the project ($N = \{0,1,2,\ldots,\bar{n},\bar{n}+1,...,\bar{n}+m,\bar{n}+m+1\}$). Each activity has a given work duration $d_i \geq 0, i \in N$ and given work content $x_i \geq 0, i \in N$. We assume that there are K types of renewable resources, and each resource $k \in \{1,2,3,...,K\}$ has a limited capacity a_k available. When a task i is executed, its requirement for resource type $k \in \{1,...,K\}$ at each time period is a fixed integer $r_{i,k} \geq 0$. Tasks 0 and $\bar{n}+m+1$ are the dummy start and end of the project ($(Task_0, Task_{\bar{n}+m+1}) \in N_{Dummy}$), whose process duration, work content and required resource are both 0. More specifically, let $N_A = \{1,...,\bar{n}\}$ denotes the active tasks that can be grouped into work packages, while $N_I = \{\bar{n}+1,...,\bar{n}+m\}$ is the inactive task set, which can only be regarded as single work package due to several fac-tors, such as the responsibility assignment, internal cohe-sion or risk control (Li and Hall, 2019); thus we can get that $N = N_A \cup N_I \cup N_{Dummy}$. A represents a set of precedence relationships among tasks, ($A \subseteq N \times N$), if $(i, j) \in A$ that means $Task_j$ cannot start before $Task_i$ is finished. W is the set of weights on the arcs that denotes the minimum time lags between tasks grouped into a single work package, $W = \{\delta_{i,j} \geq 0 | (i, j) \in A\}$. When $s_i - s_j > \delta_{i,j}, (i, j) \in A$ is satisfied, the $Task_i$ can be conducted, where s_i and s_j are the start times of tasks i and j,respectively. More specifi-cally, (1) if $\delta_{i,j} = 0$, then tasks i and j can be completely overlapped, i.e. they can be executed in parallel; (2) if $d_i \geq \delta_{i,j}$, then tasks i and j can be partially overlapped, i.e. activity j can only begin after activity i has been in ex-ecution for at least $\delta_{i,j}$ time units; (3) if $\delta_{i,j} \geq d_i$, then tasks i and j are executed sequentially, i.e. activity j can only begin after activity i is completed. Figure 1 presents an example illustrating the above three cases of activity overlap, namely, complete overlap, partial overlap, and no overlap with respect to two tasks. These variables and additional notation are summarized in Table 1.

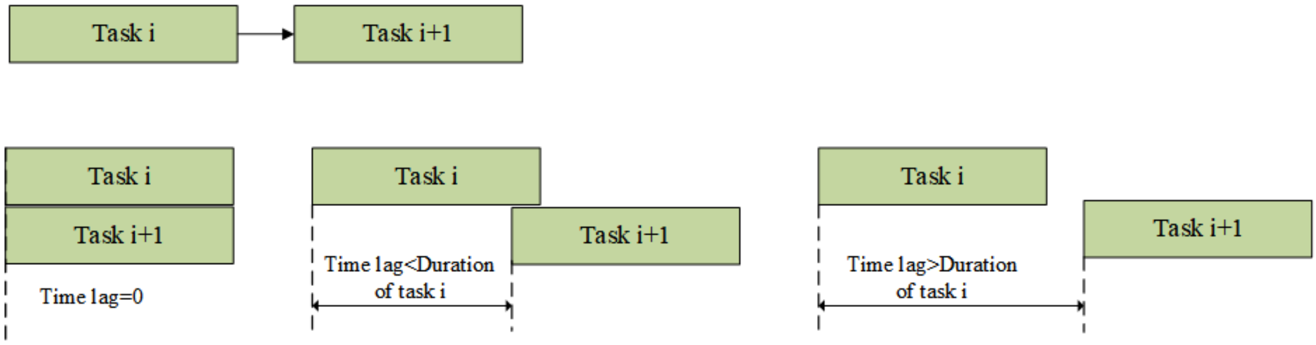

Figure 1: The lag time of the tasks.

The Objective Function

In this study, we adopted a combination of objectives (minimize the total project makespan and project cost) to optimize the work package sizing and work package scheduling in a resource-constrained environment (Li and Hall, 2019). Assuming that all the tasks are ready to be allocated to a total of $\bar{n}+m$ work packages, the objective function can be expressed as follows:

$$Minimize \qquad J = \lambda F_t + (1-\lambda)F_c, \tag{1}$$

$$F_c = \omega(p+m) + \sum_{j=1}^{\bar{n}+m} F(X_{w_j}) + \xi \sum_{j=1}^{\bar{n}+m} X_{w_j}(1-e^{-\alpha C_{w_j}}), \tag{2}$$

$$F_t = Max(C_{w_j}), \qquad \forall j \in \{1,2,...,\bar{n},...\bar{n}+m\} \tag{3}$$

$$F(X_{w_j}) = f(X_{w_j}) + g(X_{w_j}) + h(X_{w_j}), \quad \forall j \in \{1,2,...,\bar{n},...\bar{n}+m\} \tag{4}$$

where F_c and F_t are the project cost and makespan, and λ is the weight of the time part. For the most part, $p \in \{\bar{p}, \bar{p}+1,...,\bar{n}+m\}$ is the number of work packages that contain at least one task, where $\bar{p}$ is the lower bound for any feasible solutions that can be derived from the theory of critical path. ω is the fixed cost of the work package and X_{w_j} is the j_{th} work package's work content. C_{w_j} is the complete time of the j_{th} work package. We model the cost of inaccuracy in time estimation of a work package as function $f(X_{w_j})$, the cost for monitoring and controlling the progress of the work package as function $g(X_{w_j})$ and the economies of scale from repetition and similarity of tasks within a work package as function $h(X_{w_j})$, which are functions of the work packages' work content. Additionally, work package sizing poses impacts on cash flow, which is modeled as $\xi \sum_{j=1}^{\bar{n}+m} X_{w_j}(1-e^{-\alpha C_{w_j}})$, where ξ and α are parameters for cash flow cost function.

Work Package Sizing Constraints

work package sizing is conducted based on the structure of the given activity network and relies on the requirement that the network of work packages cannot contain cycles (Lambrechts et al., 2008). Additionally, the active tasks need to be allocated to the work package $P_A \in \{1,2,3,...,\bar{n}\}$, while the inactive tasks should be allocated to $P_I \in \{\bar{n}, \bar{n}+1,...,\bar{n}+m\}$. $b_{i,j}$ is the decision variable, which is 1 if activity $i \in N$ is allocated to work package $j \in P_A \cap P_I$, and 0 otherwise. The work package sizing constraints are as follows:

$$b_{i,j} + b_{i',j} \le 1, \qquad \forall i,i' \in N_A, \quad \forall i' \in \bigcup_{i'' \in Succ(i) \cap N_I} Succ(i''), \forall j \in \{1,2,3...,\bar{n}\} \tag{5}$$

$$b_{i,j} + b_{i',j} \le 1, \qquad \forall i,i' \in N_A, \quad \forall i' \in \bigcup_{i'' \in Pre(i) \cap N_I} Pre(i''), \quad \forall j \in \{1,2,3...,\bar{n}\} \tag{6}$$

$$b_{i',j} b_{i'',j} \le b_{i,j}, \qquad \forall i,i',i'' \in N_A, \quad \forall i' \in Succ(i), \quad \forall i'' \in Pre(i), \quad \forall j,j' \in \{1,...,\bar{n}\} \tag{7}$$

$$\sum_{j \in P_A} b_{i,j} = 1, \qquad \forall i \in N_A \tag{8}$$

$$\sum_{j \in P_I} b_{i,j} = 1, \qquad \forall i \in N_I \tag{9}$$

$$\sum_{i \in N_I} b_{i,j} = 1, \qquad \forall j \in P_I \tag{10}$$

$$z_j = max\{b_{i,j}\}, \qquad \forall j \in P_A, \quad \forall i \in N_A \tag{11}$$

$$p = \sum_{j \in P_A} z_j, \tag{12}$$

$$X_{w_j} = \sum_{i \in N} b_{i,j} x_i, \qquad \forall j \in \{1,...,\bar{n}+m\} \tag{13}$$

$$r_{w_j,k} = \sum_{i \in N} b_{i,j} r_{i,k}, \qquad \forall j \in \{1,...,\bar{n}+m\}, \quad \forall k \in K \tag{14}$$

$$b_{i,j} \in \{0,1\}, \qquad \forall i \in N, \quad \forall j \in \{1,...,\bar{n}+m\} \tag{15}$$

$$z_j \in \{0,1\}, \qquad \{\forall j \in 1,2,...,\bar{n}+m\} \tag{16}$$

where constraints (5)-(6) refer to that if an inactive task i'' is a predecessor/successor of activity i, then no predecessor/successor of task i'' should be grouped into the same work package with activity i. Constrain (7) shows that any pairs of a predecessor and a successor activity of active activity i are not allowed to be grouped into a single work package while without activity i. Otherwise, there will be a cycle in the work packages network. constraints (8)-(10) represent that an active/inactive activity can only be allocated to an active/inactive work package, and each inactive work package only contains a single inactive task. We il-

Table 1: Nomenclature

Notaion	Explanation
N	The set of project tasks.
N_A	The set of active tasks.
N_I	The set of inactive tasks.
N_{Dummy}	The set of dummy tasks.
K	The set of resource types.
T	The set of time.
P_A	The set of work packages for active tasks,$P_A = \{1,2,3,...,\bar{n}\}$.
P_I	The set of work packages for inactive packages, $P_I = \{\bar{n}+1, \bar{n}+2, \bar{n}+3, ..., \bar{n}+m\}$.
d_i	Duration of task $i \in N$.
$r_{i,k}$	The quantity of required resource $k \in K$ for task $i \in N$.
$\delta(i', i)$	Time lag between task $i \in N_A$ and task $i' \in N_A$.
a_k	The initial quantity of resource $k \in K$.
c_k	The cost of each unit of resource $k \in K$.
x_i	Work content of task $i \in N$.
$b_{i,j}$	1 if task $i \in N_A$ is allocated to active work package $j \in P_A$; 0 otherwise.
$q_{i,t}$	1 if task $i \in N$ starts at time t; 0 otherwise.
$a_{j,t}$	1 if work package $j \in P_A \cap P_I$ is processed at time t; 0 otherwise.
z_j	1 if active work package $j \in P_A$ is not empty; 0 otherwise.

lustrate the relationship between the active tasks and the active work packages in Constraint (11) and Constraint (16). If some active tasks are grouped into active work package j, z_j is 1, which means that the active work package is not empty, and 0 otherwise. Constraint (12)-(14) shows that we can get p effective active work packages that are not empty, and the work content and the resource requirement of these work packages are the sum of the tasks in the corresponding work package. Constrain (15) shows that $b_{i,j}$ is a binary decision variable.

Work Package Scheduling constraints

Assuming that the project is conducted within $T \in (T_{lower}, T_{upper})$ time units, where T_{lower} and T_{upper} are the lower bound and upper bound of a project. They can be estimated by the project's activity graph. Taking into account the presence of precedence and resource constraints both among work packages and tasks within the same work package, we outline the following work package scheduling constraints:

$$\sum_{t \in T} t q_{i,t} = s_i, \qquad \forall i \in N \tag{17}$$

$$\sum_{t \in T} q_{i,t} = 1, \qquad \forall i \in N \tag{18}$$

$$s_i \geq b_{i',j} C_{w_j} (1 - b_{i,j}), \qquad \forall i \in N, \quad \forall j \in P_A \cup P_I, \quad \forall i' \in Pre(i) \tag{19}$$

$$s_i \geq b_{i,j} b_{i',j} (s_{i'} + \delta(i', i)), \qquad \forall i \in N_A, \quad \forall j \in P_A, \quad \forall i' \in Pre(i) \cap N_A \tag{20}$$

$$c_i = d_i + s_i \qquad \forall i \in N, \tag{21}$$

$$S_{w_j} = min\{s_i b_{i,j}\}, \qquad \forall i \in N, \quad \forall j \in \{1, ..., \bar{n}+m\} \tag{22}$$

$$C_{w_j} = max\{c_i b_{i,j}\}, \qquad \forall i \in N, \quad \forall j \in \{1, ..., \bar{n}+m\} \tag{23}$$

$$a_{j,t} = \sum_{i \in N_I} \sum_{t'=t-d_i+1}^{t} b_{i,j} q_{i,t'}, \qquad \forall j \in P_I \tag{24}$$

$$\sum_{i \in N_A} \sum_{t'=t-d_i+1}^{t} b_{i,j} q_{i,t'} - M a_{j,t} \leq 0, \qquad \forall j \in P_A \tag{25}$$

$$a_k \geq \sum_{j=1}^{\bar{n}+m} r_{w_j,k} a_{j,t}. \qquad \forall t \in T \tag{26}$$

$$q_{i,t} \in \{0,1\}, \qquad \forall i \in N \tag{27}$$

$$a_{j,t} \in \{0,1\}, \qquad \forall j \in P_A \cap P_{I]} \quad \forall t \in T \tag{28}$$

where the variables s_i and c_i represent the starting time and completion time of activity i, while S_{w_j} and C_{w_j} represent the starting time and completion time of work package j, respectively. The decision variable $q_{i,t}$ in constrain (17) corresponds to the start processing time of the i_{th} activity, taking a value of 1 if activity i starts at time t, and 0 otherwise. Constraint (17) indicates that task execution is non-preemptive. Once a task starts at time t, it will continue without interruption until the task is complete. Constraints (19)-(20) enforce precedence constraints on the start time of task i. More specifically, constraint (19) ensures that task i can only begin after all the predecessor work packages have been completed. Constraint (20) specifies that the start time of activity i within work package j must not exceed the start time of the preceding activity within the same work package, and any required lag time must be satisfied prior to execution. Constraints (22)-(23) indicate that the starting and completion times of the work package are determined based on the earliest and latest starting and completion times of the tasks within that work package. Specifically, constraint (22) specifies that the starting time of the work package cannot be later than the earliest starting time among its tasks. On the other hand, constraint (23) ensures that the completion time of the work package is not earlier than the latest completion time among its tasks. After that, constraints (24)-(26) give the resource constraints for the work packages. $a_{j,t}$ is 1 if any tasks in work package w_j is processing at time t, 0 otherwise. Constrain (24) gives $a_{j,t}$ for inactive work packages while constrain (25) gives it for active work packages using the big-M method. Constraint (26) illustrates that the amount of resources $\sum_{j=1}^{\bar{n}+m} r_{w_j,k} a_{j,t}$ needed by all the executing work packages at any time t should not exceed the current amount of available resources a_k.

Experiments and Analysis

This section validates the effectiveness of the proposed work package sizing and scheduling model with nine projects from Rangen (Demeulemeester et al., 2003; Vanhoucke et al., 2008). These nine projects are categorized into three types, each consisting of a different number of tasks: 10, 20, and 30, respectively. The experiments are conducted using Gurobi 11.0 optimization software and executed on a PC platform running the Windows 11 64-bit operating system, Intel i9-13900KF processor.

Validation of Our Model

To obtain the nine projects, we first generate the task networks using RanGen2 with the following network measures:

- Network size indicator I_1: the number of the tasks including the active tasks and inactive tasks.
- Serial or parallel indicator I_2: $I_2 = (\eta - 1)/(I_1 - 1)$, where η is the depth of the network, and $0 \leq I_2 \leq 1$.
- Resource factor RF: an indicator of average resource availability

$$\mathrm{RF} = \frac{1}{nK} \sum_{i=1}^{n} \sum_{k=1}^{K} \begin{cases} 1, & \text{if } r_{ik} > 0 \\ 0, & \text{otherwise} \end{cases}$$

- Resource strength (RS): an indicator of resource availability at the peak time, where $r_k^{\min} = max\{r_{i,k}\}, \forall i \in N$ and $r^{\max}$ is the peak requirement of resource $k \in K$ in a schedule with the precedence constraints

$$\mathrm{RS}_k = \frac{a_k - r_k^{\min}}{r_k^{\max} - r_k^{\min}} \quad (29)$$

If the value of I_2 approaches 1, the generated network exhibits characteristics similar to a serial network, where tasks are sequentially executed. Conversely, if I_2 approaches 0, the network resembles a parallel network, where all tasks can be executed simultaneously. RF represents the typical distribution of resource types that are requested by each activity, while RS serves as a metric for assessing the level of complexity involved in scheduling a project that is constrained by limited resources. As for the remaining network measures of RanGen, we utilize their default settings to ensure consistency and comparability in our analysis. We have defined the following parameters for the three groups of project instances: I_i is set to $\{10, 20, 30\}$, I_2 is set to $\{0.8, 0.8, 0.8\}$, RF is set to $\{0.4, 0.4, 0.4\}$, RS is set to $\{0.2, 0.2, 0.2\}$ and $K = 4$. To evaluate the performance of our model, we have generated three test instances for each group, resulting in a total of nine instances. In accordance with the work by Li and Hall (2019), we have set the discount rate as $\alpha = 0.00025$, and used values of $\lambda = 0.5, \omega = 50$, $\xi = 50$, $f(x) = 3x^{0.8}$, $g(x) = h(x) = x^{1.2}$, to define our objective function. Although Gurobi is more proficient in solving linear models, our problem includes a nonlinear objective term. However, by introducing auxiliary variables, we can still utilize Gurobi to solve it.

The results of the nine projects from RanGen are presented in Table 2. In Group 1, each project instance consists of 10 tasks (nodes), with 8 active tasks and 2 inactive tasks. All experiments for this group were completed within 520 seconds, yielding objective values of 317.31, 325.29, and 304.84 for Project 1, Project 2, and Project 3, respectively. In Group 2, each instance comprises 20 tasks, with 14 active tasks and 6 inactive tasks. However, the running time for each experiment significantly increased, with Project 4, Project 5, and Project 6 taking 15,007, 24,428, and 23,674 seconds, respectively. The corresponding objective values for these projects are 516.16, 579.00, and 532.21. Projects in Group 3 consist of 21 active tasks and 9 inactive tasks, with a total of 30 tasks packaged into approximately 18 packages. Although we were able to achieve objective values of 815.70, 869.14, and 765.43 for Project 7, Project 8, and Project 10, respectively Balouka and Cohen (2021).

Overall, the results of these experiments provide compelling evidence to support the effectiveness of our modeling method that integrates work package sizing and scheduling in a resource-constrained environment. Additionally, our model takes into account the significance of striking a balance between timely completion, reasonable management cost, and maintaining a healthy cash flow in real-world construction projects. This is demonstrated in Table 2, where the makespan is included as part of the objective. By incorporating these relevant practical considerations, our model offers a more comprehensive and realistic solution for effectively managing construction projects in real-world scenarios.

Indicator	Group 1			Group 2			Group 3		
	P 1	P 2	P 3	P 4	P 5	P 6	P 7	P 8	P 9
Node	10	10	10	20	20	20	30	30	30
$Node_A$	8	8	8	14	14	14	21	21	21
$Node_I$	2	2	2	6	6	6	9	9	9
Runtime	131	520	473	15007	24428	23674	98078	107645	188763
Packages	8	8	8	11	12	12	18	17	18
Makespan	41	39	30	75	88	56	105	89	98
Objective	317.31	325.29	304.84	516.16	579.00	532.21	815.70	869.14	765.43

Sensitivity Analysis

Given the significant impact of resource availability on the work package sizing and scheduling process in our problem, we conducted a sensitivity analysis to further investigate this relationship. During the sensitivity analysis, we systematically varied the resource availability levels with project 1 in group 1 (with resource {10,10,10,10}, {20,20,20,20}, {30,30,30,30} and {50,50,50,50}) and observed the corresponding changes in work package sizes. Figure 2 illustrates the initial structure of the tasks, while Figure 3 shows the work package structure under an environment with 10 units of each type of resource. Due to the limited resource availability, it is not feasible to group tasks into a single package. As a result, the work package structure remains the same as the initial one.

As the resource availability increases, more tasks can be grouped into packages. In Figure 4 and Figure 5, where there are 20 and 30 units of resources respectively, we observe the presence of 8 packages, with each package accommodating a maximum of 3 tasks. Figure 6 demonstrates a scenario where resource availability is no longer a constraint. This allows tasks to be packaged as long as the precedence constraints are satisfied. As a result, the number of packages is minimized. Overall, these figures highlight the impact of resource availability on the work package structure. With limited resources, fewer tasks can be grouped together, resulting in a larger number of packages. However, as resource availability increases, more tasks can be efficiently packaged, leading to a decrease in the number of packages.

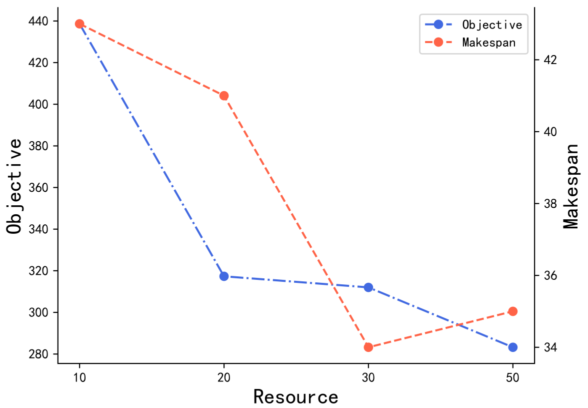

Figure 7: The comparisons of the makespan and objection.

Figure 7 presents a line graph showcasing the relationship between the objective function and makespan as the resource availability varies. As the resource availability increases from 10 to 30, the objective function shows a declining trend, decreasing from 440 to 290. This indicates that with more resources allocated, the total project cost decreases, reflecting improved efficiency and cost-effectiveness. However, when the resource availability reaches 50, the objective function starts to increase, reaching a value of 305. This suggests that excessive resource allocation beyond a certain point can lead to resource waste and increased project costs. Therefore, it is crucial to determine the appropriate level of resource availability that strikes a balance between cost reduction and resource utilization. In contrast, the makespan shows a declining trend as resource availability increases. This means that with more resources, the project duration or completion time decreases. This aligns with the intuition that additional resources enable tasks to be completed more quickly, resulting in a shorter overall project duration.

Conclusions

This paper presents an integrated model that addresses the challenges of work package sizing and scheduling in resource-constrained construction projects. To validate the effectiveness of our model, we utilized Gurobi, a powerful optimization solver, to search for optimal solutions, which demonstrates our model's effectiveness. Furthermore, we conducted an analysis to investigate the influence of resource availability on the work package sizing and scheduling process. By considering different resource levels, we find that proper resources are crucial for reducing the project's cost. However, solving our problem using Gurobi is time-consuming and not suitable for practical applications. In the future, we plan to develop algorithms that can efficiently solve our problem.

DYNAMIC MATERIAL PASSPORTS FOR SUSTAINABLE MATERIAL MANAGEMENT: A CONCEPTUAL FRAMEWORK

Ioannis Markou[1], Derek Sinnott[1], and Ken Thomas[1]
[1]Department of Architecture & Built Environment, South East Technological University (SETU), Waterford City, Co. Waterford, Ireland

Abstract

The Construction sector faces a pressing need for whole life cycle sustainable material management. This paper presents the development of a theoretical framework for Dynamic Material Passports. Existing literature identified that Material Passports concept is new, lacking real-time updates and standardized methods with limited data and accuracy. Additionally, the current extensive manual input process discourages adoption. The framework, aligned with the ISO19650 standard, encompasses vital material information, environmental metrics such as Life-Cycle Assessment Data and Circularity Index, with real-time updates. This innovative framework enhances whole life material management, empowering industry stakeholders to make more informed Design and Procurement decisions.

Introduction

The construction industry stands as a substantial contributor to environmental harm, encompassing issues like natural resource depletion, waste generation, and greenhouse gas emissions (MacArthur Foundation, 2022; UN, 2016). In response to these pressing challenges, there has been a growing emphasis on the adoption of circular economy principles in recent times. The Circular Economy (CE), as an economic model, is aims to maximize the utilization of resources, minimize waste, and reduce adverse environmental impacts (MacArthur Foundation, 2022) In this context, Dynamic Material Passports (DMPs) emerge as a promising tool within the Architecture, Engineering, and Construction (AEC) sector.

In the Built Environment (BE), Material Passports (MPs) function as digital records, meticulously documenting the materials employed in construction, from their composition to their origin and location, throughout their lifecycle. This important information opens avenues for the efficient reuse, recycling, or repurposing of materials, significantly reducing waste, and promoting resource efficiency (Çetin, Straub, et al., 2022; Honic, Kovacic and Rechberger, 2019a, 2019b).

Nevertheless, considering its potential, the deployment of MPs faces certain challenges, particularly lack of standard methods of creation, compatibility, and currently have static form, without real-time updates (Honic et al., 2021)To address those obstacles, this research paper seeks to provide with a BIM-based framework for the development of DMPs, aligned with the information management processes described in EN ISO 19650, part 2 for a BIM level 2 project, that will promote CE practices in the BE. BIM is a form of digital technology that involves the creation and management of a digital model of a building, which include both its functional and physical properties (Becker et al., 2018). When it is used during design, construction, and operational stages, it creates a detailed and simple to access record of the materials used (M. Honic et al., 2019).

Hence, this research paper discusses the gaps based on the current state of MPs, the preliminary findings, and a proposed conceptual framework, which aims to fill the gaps identified from the literature review. The proposed framework involves four key stages: data collection, data management, data analysis, and data dissemination.

Literature Review

MPs and CE

Over the pass years, the construction industry is experiencing a significant transformation, and the emerging concept of MPs plays a crucial role to it (Çetin et al., 2022b). They have the ability to significantly improve resource management processes and the same time to simplify the transition of the BE to a CE perspective (Honic et al., 2021, 2019a, 2019b; Soman et al., 2022).

MPs, as comprehensive documentation systems, provide in-depth information about construction materials and products throughout their life cycle, covering details about their origin, characteristics, and environmental and sustainability attributes (Honic et al., 2019a; Kedir et al., 2021) Some example of data that may be included in MPs are manufacturing information, physical properties, chemical or biological properties, quality of material, design related information, location and transportation information, disassembly/ deconstruction manuals and sustainability information, such as embodied carbon and Circularity Index (Stella et al., 2023).

The Circularity Index or Indicator was developed by Ellen Macarthur Foundation (2016), as a tool for measuring the materials circularity, considering the amount of recycled material content the potential for reuse and recyclability of materials. It is calculated on the scale of 0% to 100%, with the higher percentage indicating the higher circularity. This indicator it can be used to assess the circularity of individual materials and products (Ellen Macarthur Foundation, 2016). Similarly, Madaster, a Dutch company that developed a digital platform for producing MPs, developed the Building Circularity Index based on MacArthur's Circularity Indicator, which measures the circularity of a building, taking into consideration the amount of recycled materials used in a building (Madaster, 2018).

Also, it was found that there are different levels of MPs (Çetin et al. 2023). At the product level, "Material-Level Passports" set the foundation, while at the “Building level”, specific design stages come into play (Çetin et al. 2023a; Stella et al. 2023). During “Design for construction stage” detailed material specifications are introduced while at construction stage with documentation of “as-built” information is complied, and “in used” stage focusing on the operational phase with regular updates to the MPs. For “End-of-life” stage marks the identification of information crucial for the considerations (Stella et al., 2023).

Historically, the BE has followed a linear economic model defined by resource consumption, use and disposal of building materials with the creation of significant amount of waste (MacArthur Foundation, 2022). Such an approach is both ecologically untenable as well as financially inefficient. Considering the current concerns about resource scarcity, deterioration of the environment, and global warming to move to a more circular and sustainable system for managing construction materials (Çetin et al., 2022a; Charef, 2022).

Therefore, as a fundamental concept, CE aspires to reduce waste and increase resource efficiency by encouraging recycling, reuse, and repurposing of materials across their life span (MacArthur Foundation, 2022). It encourages to “close the loops”, from a linear economy to a more circular, in which items and materials are continuously refurbished, reused, and remanufactured, lowering the demand for raw materials and reducing the ecological effects of waste disposal (Pomponi and Moncaster, 2017).

Also, the implementation of MPs in the BE is completely compatible with the CE principles (Çetin et al., 2023; Çetin, Straub, et al., 2022). They can assist in the tracking, control and optimization of the use of building materials (Atta et al., 2021; Honic, Kovacic and Rechberger, 2019a; Munaro and Tavares, 2021). Additionally, they can provide comprehensive information on each material used in a building, providing accurate and thorough documentation through the building’s entire life span. MPs can also assist stakeholders to make informed decisions about material procurement, selection and consumption with focus on sustainability and resource efficiency (Honic et al. 2019a; Munaro and Tavares 2021).

MPs and Building information Modelling (BIM)

BIM constitutes an advanced technological method that effectively combines planning, design, construction, and asset management in the BE. This digital tool, which assist to the representation both the functional and physical features of building assets allow successful cooperation among stakeholders (Becker et al., 2018).

Furthermore, BIM encourages transparency, collaboration, and decision-making based on data throughout the life circle of a building boosting sustainable practices and waste reduction (Pishdad-Bozorgi et al., 2018; Sacks et al., 2018).

The combined approach of BIM and MPs offer great potential for sustainable building practices, since it provides a digital basis for a detailed 3D model (Alshammari et al., 2021; Pehlken and Baumann, 2020; Shahzad et al., 2022). Hence, a BIM-based method of producing a MP can be employed to improve the building design by considering resource efficiency and detailed documentation of materials used. BIM is used as a resource of information regarding the material quantities, overall building geometry and location within the building, while linking secondary databases to obtain their physical properties and evaluate their environmental impact or recycling potential(Honic et al., 2019a).

Additionally, the combination of MPs with BIM contributes to the successful collection and storage critical information on building materials increasing transparency and efficiency (Atta et al., 2021). A good example of that is a case study in Egypt, where a parametric BIM model permitted the automatic development of sustainable metrics for a residential building. This demonstrated that BIM improved the sustainability of the project through the use of resources efficiently, decreasing waste and enabling material monitoring for reuse (Atta et al., 2021). The BIM-based method takes use of the technologies capacity to integrate environmental impact evaluations via Life Cycle Assessment (LCA) via, giving a holistic approach to developing of sustainable buildings (Atta et al., 2021; Honic et al., 2019a; Kedir et al., 2021). Additionally, this combination can foster CE concepts in the BE by increasing transparency, traceability and accountability during the asset’s life cycle (M. Honic et al., 2019).

LCA is a standardised method for assessing the environmental impact of a product, throughout its lifecycle and is based on ISO 14040, It includes greenhouse gas (GHG) emissions which is measured through Global Warming Potential (GWP). GWP is expressed in the equivalent amount carbon dioxide (CO_2) (McGrady, 2022). Other indicators that are used in LCA are Acidification Potential (AP) measuring the potential of emissions to cause acidification, and ISO 14040 describes that LCA is carried out in four steps: goal and scope definition, inventory analysis, impact assessment and interpretation (Muralikrishna and Manickam, 2017).

However, BIM is more than 3D visual representation, they contain essential data about the building’s structure and its elements (Volk et al., 2014). An effective exchange of information can be achieved through Industry Foundation Classes (IFC) (buildingSMART, 2023). IFC was created by BuildingSMART as an open standard for transferring building data amongst different BIM tools. It also assures the compatibility and vendor neutrality, allowing project teams to use their preferred software while ensuring data usability (Jiang et al., 2019) IFC classes are also specified in ISO 19650 series as am appropriate format of storing the BIM model, due to interoperability (Earley Michael et al., 2022). Moreover, Madaster platform, allows uploading the BIM model in IFC format, in order to produce MPs (Madaster, 2023).

MPs and Artificial Intelligence (AI)

The data compilation for creating MPs has been traditionally a time-consuming operation. As some researchers stated, manual procedures need precise data gathering, which is a laborious and inclined to errors (Honic et al., 2021, 2019a; Hunhevicz et al., 2023; Kovacic et al., 2020). Hence, they are an urgent need for standardized protocols and tools (Atta et al., 2021; Göswein et al., 2022) which created the ground work for Deep Learning (DL), a particular type of AI. DL specializes in optimizing and automating complex procedures in MPs development (Akanbi et al., 2020; Oluleye et al., 2023), providing immediate updates and precision across the building's lifespan (Çetin et al., 2022a).

DL, was influence by the functions of human brain, emerging this way, as a transforming force in CE activities. Its forecasting ability is aligned with the requirements of sustainable material management (Lu and Chen, 2022), enabling the creation of a more sustainable BE adaptable to changing demands. Contrary, Machine Learning (ML), is based on algorithms that analyses and forecast based on data (Noman et al., 2022). ML is extremely useful for CE as it can assess material consumption patterns and foreseeing trends for enhancing resource (Çetin et al., 2023). Through sophisticated algorithms, both DL and ML provide possibilities for developing a circular BE, outcoming from technological, economic environment and social aspects (Akanbi et al., 2020; Oluleye et al., 2023).

The selection of an AI approach for developing an MP framework requires a considerable deliberation. Current research describes three approaches for developing MPs: the top-down, the bottom up and hybrid methods (Honic et al., 2021), that demand an extensive understanding of the building materials. As a result, such methods may be easier to be examined by DL given that they have higher accuracy, flexibility and capacity to handle large datasets, making it the best choice, enabling stakeholders taking better decisions.

Current state of MPs

The present form of MPs in the BE includes technological, economic, environmental, and social factors. Current studies proposed that a standardized method for generating and managing MPs, pointing out the need of uniformity and accessibility (Atta et al., 2021; Honic et al., 2019a). Several studies restate the need for consistent guidelines and protocols across the sector (Göswein et al., 2022; Negendahl et al., 2022).

In respect to technological factors, current methods of creating MPs can be quite laborious. Their creation requires substantial time as it involves to extract material information from the BIM model to an excel file, collect information from material inventories and then manually input in the excel document, which will finally be linked back to the BIM model, using unique identifiers (Atta et al., 2021; Honic et al., 2019a; Kovacic et al., 2020).

The implementation of MPs is also considered as economically feasible with possible cost decreases through material reuse (Smeets et al., 2019). Furthermore, significant economic benefits can be achieved through the digitalization of MP (Çetin et al., 2022a), in conjunction with the best practices (Heinrich and Lang, 2019).

From an environmental perspective, MPs are touted as catalysts for sustainability, enabling high levels of material recycling (Honic et al., 2019b)s and stock flow modelling emphasize the potential to calculate circularity (Göswein et al., 2022; Negendahl et al., 2022).

On the social front, transparency, accountability, and stakeholder engagement take centre stage. Digital platforms integrating MPs with stakeholder engagement are recommended (Hunhevicz et al., 2023; Kovacic et al., 2020). The importance of stakeholder engagement, especially in the end-of-life stage of buildings, is highlighted (Honic et al., 2021). Additionally, local scenarios play significant role on the choice of sustainable construction materials, as evidenced by a case study suggesting that a building MP for wood construction system in Brazil, could significantly reduce the environmental impact of construction versus more conventional materials, such as a concrete and steel (Munaro et al., 2019).

Gaps and Challenges

MPs have great potential with their deployment in the BE although they are facing significant challenges. Their major disadvantage is their static form, that limit them to no frequent updates, that are necessary to accurately reflect real-time changes in a material's composition, condition, and lifecycle, enabling informed decision making for sustainable resource management and end-of life strategies (Atta et al., 2021; Kovacic et al., 2020). Their stationary state compromises MPs' adaptive perspective, in terms or real-time updates, reducing their level of accuracy and efficacy through sustainable material management. Due to that static nature and high level of manual input for updating material data also their inability of optimizing and automate processes reduce their long-term effectiveness (Atta et al., 2021; Honic et al., 2019a; Kovacic et al., 2020) .

Another challenge for the development of MPs is the lack of a standardized methods for compiling MPs. MPs appear in a variety of formats, including paper-based and digital, with varied degrees of details, causing in inaccuracies and limiting sharing of data among stakeholders (Heinrich and Lang, 2019; Honic et al., 2021). Developing a consistent approach for producing MPs is critical that contributes to the reduction of errors and ensuring that correct information is exchanged between the stakeholders such as AEC professionals, waste managing and material suppliers (Kovacic et al., 2020).

Another challenge that affects the implementation of MPs in the BE, is the insufficient incentives for their implementation. MPs adoption is not adequately motivated by the current economic and regulatory frameworks, but also the BE gives higher priority to the speed and cost reduction rather than sustainability (Göswein et al., 2022). In order to promote the broad use of MPs, policymakers must provide regulations and incentives, such as tax reliefs or financing green procurement for sustainable construction (Smeets et al., 2019).

A further obstacle involves the quality, accessibility and data administration. All building materials have different origin, making it difficult to collect and maintain their specific data (Atta et al., 2021; Honic et al., 2019a). To guarantee the accuracy and accuracy of MPs data, improved data management systems and quality control techniques are required. Additionally, the environmental implications of building materials are frequently neglected, when implementing MPs. There is no assessment of the materials' long-term environment impacts in the existing MPs frameworks (Heisel and Rau-Oberhuber, 2020). To provide a thorough understanding about their environmental effects, using standardized methods for environmental assessments into MPs frameworks.

MPs also face challenges related to the end-of-life state of buildings, such as disassembly or deconstruction instructions. Therefore, buildings are often thought to be demolished as the best solution, rather than carefully dismantled, leading to destruction of possible healthy reusable materials, creating this way construction waste. Hence, by integrating MP data into waste management strategies can help avoid unnecessary demolition and waste, preserving essential materials and resources (Honic et al., 2019b). Successful reuse and recycling necessitate improved coordination among stakeholders and waste management professionals.

Methodology

The present research provides a conceptual framework for Dynamic Material Passports (DPMs) using a strong approach based on in-depth literature review. The main emphasis is on analysing the present status of MPs in recent literature understanding the data needs for constructing MPs, defining how their features could be implemented in the DMPs in accordance with existing standards and finally identifying the gaps in the current state. The process entails a comprehensive literature review, followed by an inductive research approach to develop this conceptual framework. The framework is refined by a comparison of various MPs approaches, as described in "current state". The compilation of qualitative data from different methodologies adds to a practical conceptual framework, providing useful insights for its future application in the BE.

Proposed Conceptual Framework

The conceptual framework intends fill the gaps for the static data of current MPs approaches and to address the tracking of the material differenced in terms of future retrofitting and refurbishment, through a project's life circle (See Table 1). The emphasis will be initially on the creation pf DMPs at "Material level" with information that collected during the design stages. The DMPs will incorporate technologies such as BIM, GS1 barcoding standards and AI. This strategy addresses will address towards the improvement of data accessibility, accuracy and regular updating thought the building's life span.

Table 1: "Current State" Vs "Future State"

Feature	Current State (MPs)	Future State (DMPs)
Definition	Tracks and documents materials used in construction or manufacturing	Real-time, digital tracking throughout the lifecycle
Scope	One-time documentation at construction/manufacturing	Continuous monitoring and updates
Data Update	Static information; that cannot update	Dynamic, allows real-time updates
Tech. Integration	Relies on traditional methods with substantial manual input	BIM, AI, QR codes
Use	Snapshot for end-of-life recycling/reuse	Critical for asset management throughout life cycle

In the context of this study, a BIM model for a proposed new building is generated as the initial step (Step 1, Fig.1). This involves creating a digital representation of the physical structure using BIM tools like Revit and adhering to the ISO 19650 for "BIM Stage 2" modelling guidelines. Clause 5 of the ISO 19650-2 describes in detail the processes and processes that are necessary to compile the Project Information Model (PIM) during the design stages. Also, the information that will be required for DMPs will be included in the Project Information Requirements (PIR) and Exchange Information Requirements (EIR), both compiled during the process 5.1: Assessment for Need, as described in the relevant clause.

Following the PIM creation, the primary components for constructing the DMPs are identified. Recognizing the absence of a standard method for data requirements, the material data considered is refined in subsequent stages, drawing from recent literature. The data encompasses three categories: material information (type, physical properties), sustainability indicators (such as the Circularity Index), and component information (including manufacturing, installation, maintenance, disassembly instructions, and expected lifespan and performance data). Simultaneously, while setting up the initial BIM model, a material inventory is established based on information for each piece, using unique identification and names specified in ISO 19650 (Step 2, Fig.1). Also, is worth

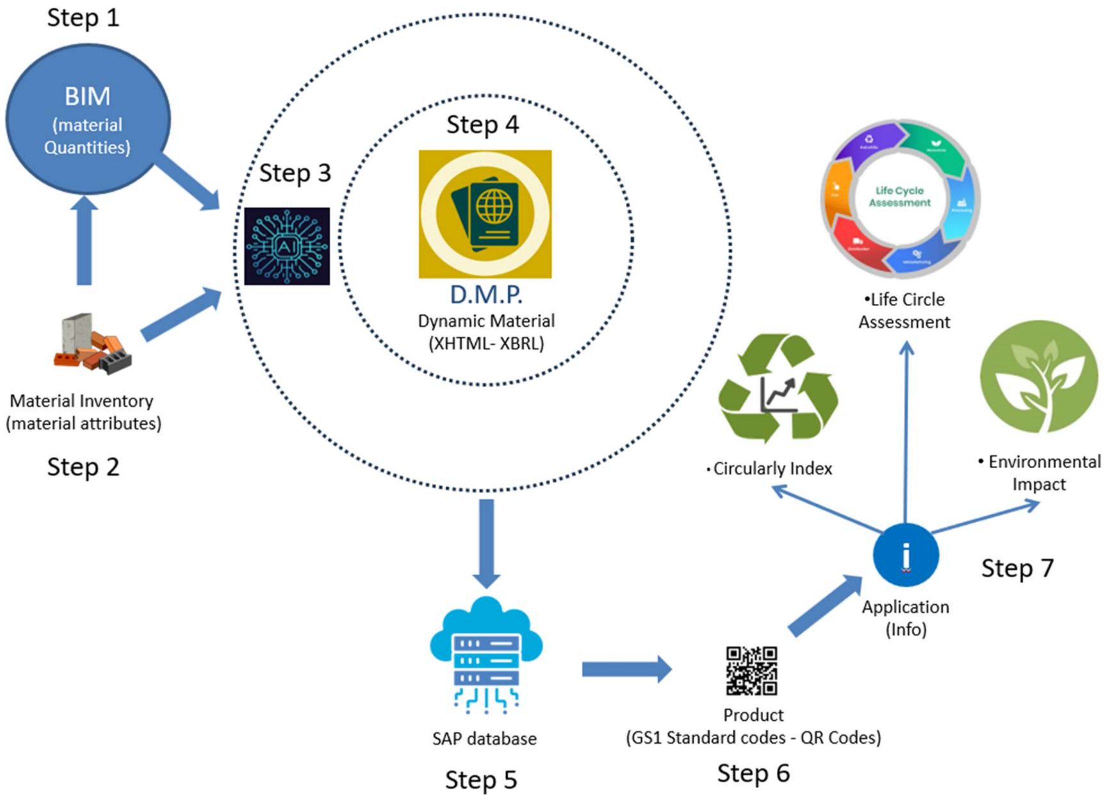

Figure 1: Conceptual framework for DMPs (own illustration)

mentioning, part of the dynamic nature of DMPs, it would require to be linked to 4D ontology. 4D ontology refers to the integration of time (the fourth dimension) into the digital representation of a building. This will enable the capturing and visualisation of how elements of the project change and interact over time, but also simulate and anticipate future changes throughout the lifecycle of the project.

AI techniques, including ML and DL, may be deployed to collect diverse attributes of the supplied content (Step 3). ML algorithms can analyse existing data sources, such as supplier documentation and manufacturing records, to identify patterns and relationships. Additionally, ML predictive models can assist in forecasting potential gaps and areas of uncertainty, prompting proactive measures. On the other hand, DL models, equipped with neural networks, are advance in processing complex and unstructured data. Furthermore, DL models, can handle sequential data, ensuring a more refined understanding of materials' dynamic attributes over time. These techniques contribute to the identification, categorization, and tracking of materials, assessing their origins, environmental impact, and even predicting future performance (Çetin et al. 2023b). DL algorithms automate material-related data acquisition from various sources like product databases, material suppliers, manufacturers, and construction documents. They can navigate websites to extract essential data from digital sources, eliminating the need for extensive manual labour.

DMPs may be created as an Extensible Hypertext Mark-up Language (XHTML) document adorned with eXtensible Business Reporting Language (XBRL) tags (Step 4, Fig.1). XHTML, as opposed to HTML, has more rigid syntax and formatting restrictions. It is also guaranteeing that web browsers and interpreter programs can process it seamlessly. Usually, it is standard practice to combine XHTML with XBL in order to ensure data integrity and interoperability across systems, particularly on the internet (Stewart, 2020).

In financial reporting, XHTML formats interconnected with XBRL tags are commonly employed, giving a dual-readable structure for both people and machines. XBRL tags are used to insert standardized and machine- readable data into an XHTML file, facilitating financial report processing and analysis. This unified technique reduces inconsistencies and simplifies the filing process, resulting in a strong resolution for financial reporting requirements (Siddle 2020; Stewart 2020). The use of XHTML with XBRL tags is an effective form for storing and evaluating material and sustainability data. Hence, the ability of XBRL to stipulate context, combined with XHTML is quite beneficial for DMPs.

The next step is proposed that store the files in Single Access Point (SAP) database, similar to European Single Access Point (ESAP) which is used for (Step 5, Fig.1). As in ESAP, SAP will provide access to publicly available information related to MPs data. Therefore, this will be consistent whit the EU' Digital Strategy and the targets of

European Green Deal, fostering transparency and accelerating decision-making for stakeholders (European Commission 2023).

SAP will constitute a regulated platform, will encompass various features, including a web portal, API for data retrieval, multilingual search function, information viewer, machine translation service, download service, and notification service for updates. This can be particularly crucial for Small and Medium Enterprises (SMEs), for future sustainable related decision-making (European Commission 2023).

The subsequent step involves exporting BIM model and data related to building elements, their layers, volumes, thicknesses, and individual components to be linked to a Quick Response code based on GS1 standards (Step 6, Fig1). Essential standards include the Global Trade Item Number (GTIN), GS1-128, Global Location Number (GLN), and Global Data Synchronization Network (GDSN) to ensure accurate and updated data accessibility across the supply chain (GS1 2023).

A method of barcoding involves Quick Response (QR) codes, with dynamic QR codes being considered for this research. Dynamic QR codes have the capability to employ an intermediate concise URL for redirecting, enabling modification of stored data within the same printed QR code. Recent research highlights the effectiveness of QR codes in tracking materials, providing essential information about each building element (Byers et al., 2022). These QR codes improve material tracking in the construction process, offering real-time updates to the MP, especially concerning location.

Real-time update is crucial will be enabled by scanning the QR code, especially during and construction phases, or refurbishments which allows access to the material's geo-location through GIS, by scanning by using a phone or tablets. Some of the building materials like concrete, steel, and brick exhibit relatively stable properties over time. Unlike dynamic assets that undergo frequent changes or degradation, the characteristics of these materials remain largely consistent throughout their lifespan. Therefore, the need for real-time updating to capture sudden variations or anomalies may be minimal, as gradual changes can be adequately monitored through periodic assessment. AI techniques, including computer vision, enable the scanning of QR codes and linking to relevant data, facilitating estimations such as embodied carbon due to transportation.

For example, a DMP for items such as electrical motors within ventilation systems which have relatively shorter lifecycle than the building structure and envelop, will allow instant access to current data on the origin, composition, and quality of its components. As the motor has been replaced, then with DMP will be easier to be tracked in order to obtain the embodied carbon. With the aid of AI, the DMP will be able to collect missing information, in respect to the physical or manufacturing characteristics, as well as LCA calculations, and updated information. The combination of the BIM 4D ontology will enable to track the motors' state over time, such operation and maintenance stages, capturing crucial details about the history and condition of motor. Also, the use of the QR codes will facilitate easier retrieval of the motor information using mobile devices, as well as tracking the geolocation. In this way, informed decision-marking is enabled, in respect to the mor' maintenance, repair, or end-of-life options and ultimately will assist to reduce the environmental impact of the motor's lifecycle. Additionally, the DMPs will include automated sustainability indicators such percentage of recyclable materials, waste, and environmental impacts, LCA calculations expressed by the use of algorithms, in terms of Global Warming Potential (GWP), Acidification Potential (AP), and Potential Energy Index (PEI) (Step 7, Fig.1). Also, the inclusion of Circularity Index created by McArthur Foundation to DMPs will allow to score the circularity of the building based on the percentage of recycled materials used. AI plays a significant role in enhancing the accuracy of these environmental impact assessments. ML algorithms process large datasets to identify patterns and correlations, providing insights into material performance and environmental impact.

Limitations and Challenges for Implementing the Conceptual Framework

DMPs implementations in the BE faces significant limitations. Those major challenges include industry's opposition, anchored in old procedures, necessitates careful positioning to explain the befits of DMPs while addressing concerns from moving traditional approaches. A further challenge is the financial limitations, particularly for SMEs, that need to deliberate cost reductions. Also, interoperability concerns between many stakeholders who use different BIM software, demand careful planning and possible plugin development. In addition to that, maintaining data accuracy among the supply chain is difficult, requiring coordinated collaborations common data dictionaries. In relation to data, concerns about privacy and security is another limitation.

Finally, the lack of standard and regulations for creating MPs and educating professionals in the use of new technologies such as DMPs could be really challenging. Considering these problems as possibilities for improvement, can lead to a more robust implementation of DMPs in the BE.

Conclusions and Future Work

The proposed conceptual framework of DMPs intends to fill the gaps of current state of MPs, such as its current static form, lack of regular real-time updates for the material information throughout a buildings life cycle which current requires a lot of manual input. This is may lead to errors and included information to be included in the MPs current state.

DMPs is proposing the use of BIM model, in conjunction with the BIM standards of ISO19650-2 "Delivery phase of an Asset", which give a detail the processes of creating a BIM model in addition to information management for a BIM level 2 project. The BIM model will provide the quantities and specific location of materials in the building. In conjunction to AI techniques of collecting and analysing complex data, and also scanning codes based on GS1 standards, will enable the DMPs to provide up-to-date information of about the construction materials. Furthermore, the incorporation of LCA into DMPs will add sustainability aspect to the framework, contribute to the reduction of the carbon footprint of the BE.

The future research will focus on the creation of the prototype DMP and further investigation of the use of appropriate AI techniques. Following the creation of the prototype, collaboration with industry will take place to run a Pilot Case study for the DMPs implementation in the BE that will allow the assessment of its effectiveness. This will allow feedback from industry that will be assessed and contributes to the continues improvement of the prototype and based on the lessons learned from this pilot study.

Acknowledgments

The Author would like to thank the co-writers of this paper for their assistance in completing this paper. Also, the author would like to express his sincere gratitude to Ms. Anastasia Stella, Sustainability Associate at Waterman's Group (UK) and co-founder of "CIRCULAND", for her support during this research. The research is funded by "Build Digital Project" from Department of Public Expenditure, Republic of Ireland.

Abstract

The construction industry is transitioning from traditional linear methodologies to the Total Life Cycle Process (TLCP) based on DIN EN ISO 19650 principles. TLCP employs database-supported information models (dIMs) and Information Requirement Matrices (IRMs) to enhance project management, focusing on sustainability. This method improves communication, ensures timely access to critical information and optimizes resource use. By integrating the Level of Information Need (LOIN) concept and web-based tools, TLCP supports agile transitions and technological adaptation. This paper showcases TLCP's practical applications, promoting sustainable construction management and encouraging industry-wide discourse, ultimately contributing to long-term environmental and economic benefits.

Introduction

The construction industry has focused on conserving resources in recent years to align with the Sustainable Development Goals (SDGs) (United Nations, 2023) and the Green Deal (European Commission, 2023). The Green Deal promotes forward-thinking actions and responsible resource management through terms such as sustainable production and sustainable decisions. These terms serve as specialized language. The importance of forward-looking planning and conscientious resource utilization is emphasised by these terms. A comprehensive strategy for managing raw materials is presented, which emphasizes savings while also promoting reuse and reduction of excess, such as construction waste. Although foundational elements in the construction industry, the sustainability factor involved in action and decision-making has not received enough attention in public discourse, despite its critical role in achieving the aforementioned goals.

The state of disrepair in infrastructure (Norddeutscher Rundfunk, 2023) has long been a public concern. The list of reasons for recent failures highlights structural flaws in the industry that neglect the life cycles of infrastructure such as bridges, roads, and railways. It is crucial to understand the temporal significance of structures and their relationship with sustainability. Infrastructure should not be viewed as disposable, but rather as part of a recurring cycle. They should not be forgotten once built. Adherence to academic norms, objectivity, and formal language is essential. The object life cycle can be divided into five phases: initiation (0), planning (1), execution (2), operation (3), and optimized initiation renewal (4). However, as the physical existence of the object is limited to phases 2 and 3, the term project life cycle is used to emphasize its place within the broader process. Sustainability is an important consideration in project management, which involves the overall execution of projects. Project management provides a more comprehensive framework for considering sustainability compared to the project life cycle.

This study aims to establish links between temporal processes and modern digitisation techniques. Additionally, this paper proposes a novel approach to developing project-specific temporal processes. This will result in clearly defined tasks that enhance project management in the construction industry. The ultimate goal is to contribute to the long-term sustainability and future prospects of the German construction sector through the use of TLCP.

Sustainability integration in lifecycle processes

In contemporary discourse, sustainability is moving beyond its traditional definition to become a multifaceted concept, often divided into three domains: economic, environmental and social (von Hauff et al., 2005). Current research efforts focus on effectively integrating these domains within work systems to facilitate concerted action, taking into account both immediate and future impacts. This holistic approach to sustainability, often referred to as the sustainable polygon, requires a thorough understanding of the underlying mechanisms, which requires iterative development and analysis in real-world contexts for practical applicability (Flemisch et al., 2023).

Skilled planners play a crucial role in the efficient use of available resources to achieve cost effectiveness in building construction, while ensuring suitability throughout the life cycle. This involves careful consideration of materials, processes and responsible resource management over the life of the building. In Germany, the Fee Structure for Architects and Engineers (HOAI) further delineates these phases, resulting in up to ten phase levels, with phase (0) serving as an initialisation or preliminary feasibility study.

However, this traditional approach to project billing in Germany has its limitations, particularly in addressing gaps and information loss during project execution, given the iterative life cycle of products and technological advances such as model-based computer systems and

Building Information Modelling (BIM). Several factors contribute to these shortcomings, including compliance with regulatory requirements, prioritisation of social needs over technical optimisation, and challenges such as lack of digitisation, transparency and effective communication (Weber-Lewerenz, 2021).

Figure 1: Stages within the project Management

Integrating sustainability principles into project management practices is essential to promote project sustainability. According to the German National Standard (DIN) 69901-5 (DIN e.V., 2023), project management encompasses various tasks, techniques and means necessary for initiating, defining, planning, controlling, coordinating and completing projects. This includes overseeing phases (0)-(3) of the product lifecycle, as shown in Figure 1. However, project management responsibility typically only extends to the end of the warranty period of the contracted services in phase (3).

Efforts to embed sustainability in project management include the simultaneous consideration of economic efficiency, material selection and social aspects (Silvius, 2017). For example, during the planning phase, conducting a product life cycle analysis can help assess the impact of actions on the three pillars of sustainability. Project management plays a critical role in either analysing the impact of sustainability measures or coordinating their implementation (Project Management Institute, 2021).

Holzbauer et al. (2021) further categorize sustainability processes in project management into three areas: internal processes, management of projects, and project-specific processes. Emphasizing a broader perspective on projects, sustainability in project management entails coordinating the overall process, networking internal and external influences, and applying known sustainability principles (Stumpf et al., 2012).

Sustainability in project management practices

To effectively embed sustainability into project management practices, it is imperative to adopt a comprehensive approach that encompasses various aspects of project execution. This involves integrating sustainability considerations into internal processes, such as resource allocation and risk management, to ensure that economic, ecological, and social factors are adequately addressed throughout the project lifecycle. Moreover, managing projects with sustainability in mind requires proactive measures to minimize environmental impact, promote social equity, and optimize economic viability.

Project-specific sustainability processes entail tailoring sustainability initiatives to meet the unique requirements of each project. This may involve conducting thorough assessments of environmental impact, implementing green building practices, and fostering stakeholder engagement to ensure alignment with sustainability goals. By incorporating sustainability principles into project management practices, organizations can enhance their reputation, reduce costs, and contribute to long-term environmental and social well-being.

In conclusion, sustainability in project management is integral to achieving lasting success in today's dynamic business environment. By integrating sustainability considerations into project planning, execution, and evaluation, organizations can mitigate risks, capitalize on opportunities, and create value for stakeholders. Through collaborative efforts and strategic initiatives, project managers can drive positive change and foster sustainable development for future generations.

Managing Information Transfer Complexity in AEC Projects

Effective information transfer is crucial for the success of AEC projects, yet it often presents significant challenges due to the multifaceted nature of project requirements and stakeholder involvement. This subsection delves into the various facets of managing information transfer complexity within AEC projects, highlighting key considerations and strategies for addressing these challenges with a focus on the German construction industry.

Navigating the regulatory landscape, including frameworks such as the HOAI, introduces complexities in information transfer processes. Compliance with regulatory requirements adds layers of intricacy to data exchange, necessitating clear understanding and adherence to legal standards. Moreover, ambiguity in information requirements further complicates the transfer process, as stakeholders may struggle to discern the specific data needed for each project phase. This ambiguity can result in inefficiencies and delays, underscoring the importance of clarifying information needs and ensuring compliance with regulatory guidelines (Mohan et al., 2021).

Effective information transfer hinges on seamless collaboration among project stakeholders, including architects, engineers, contractors, and clients.

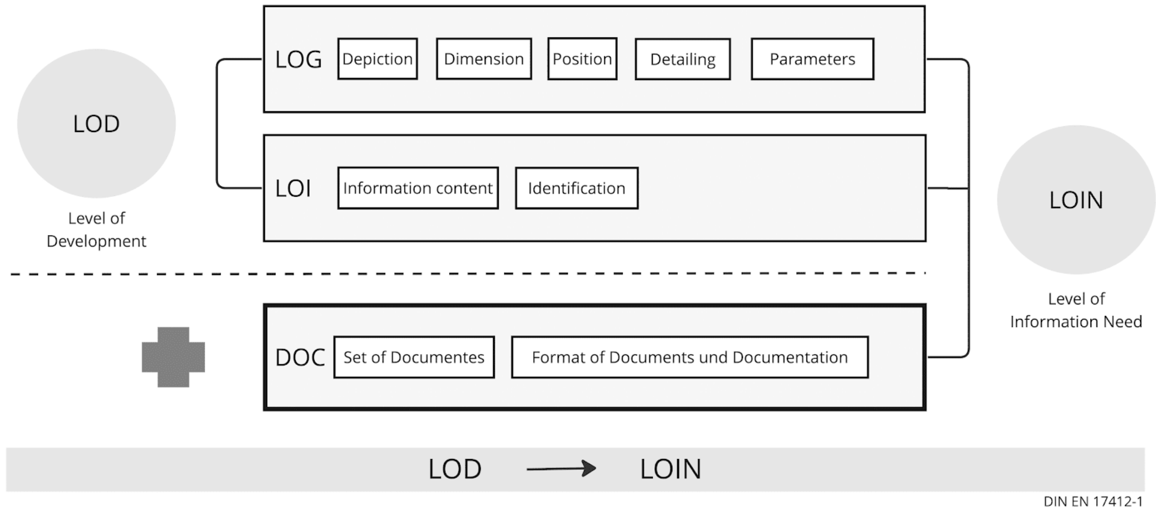

Figure 2: Level of Information Need (LOIN) (DIN e.V., 2023)

Coordinating diverse teams and aligning their efforts towards shared project goals requires robust communication channels and established information-sharing protocols. Clear delineation of roles and responsibilities, along with regular communication and collaboration platforms, fosters synergy among stakeholders, facilitating the smooth flow of information throughout the project lifecycle.

As all project participants have different starting points, it is essential to have a defined digital knowledge transfer to ensure accurate and transparent information transfer.

Table 1: Table 1: IRM concept based on LOIN use case with consideration of TLCP (Mohan et al., 2023)

Key Data	Content
Use Case	Why is the information required?
Milestone	When is the information required?
Objects	What / *Which Information* is required? (LOG/LOI/DOC)
Actors	Who required the information? ***Who delivers the information?***

Implementation of Digital Knowledge Transfer Solutions and the Effect of TLCP

In response to the challenges posed by information transfer complexity, digital knowledge transfer solutions emerge as indispensable tools for streamlining communication and data exchange. Centralized databases and information management systems provide a centralized repository for project-related information, enabling real-time updates and seamless accessibility for all stakeholders. Standardized information formats and protocols ensure consistency and accuracy in data transfer, reducing the risk of errors and discrepancies. Additionally, digital tools and technologies, such as Building Information Modelling (BIM) software, offer advanced capabilities for visualizing project data and facilitating collaborative decision-making, further enhancing the efficiency of information transfer processes (Vaatz et al., 2023).

Implementing the TLCP not only provides a comprehensive view of the product lifecycle in the AEC industry but also offers a strategic approach towards sustainable project management. Through a dIM, TLCP facilitates the structured capture, management, and exchange of project-relevant information, ensuring its availability and quality while fostering efficient communication, transparency, and collaboration among all stakeholders.

Real-time updates and easy accessibility of information in the dIM significantly enhance decision-making and planning accuracy, which are essential components in sustainable project management practices.

Incorporating sustainability principles into TLCP, Table 1 and Figure 2 outline the IRM and its components, such as Level of Geometry (LOG), Level of Information (LOI), and Documentation (DOC), forming the foundation for managing the dIM. Informed by insights gleaned from past and ongoing projects, TLCP development underscores the importance of standardized information requests and effective communication channels in sustainable project management efforts.

TLCP's capabilities, organizations can elevate their project management practices, leading to improved outcomes and greater sustainability across the industry.

Proposed methodology

Implementing TLCP in the current process relies on key factors, including adherence to national and international standards, digitalization through information models,

Table 2: IRM for Infrastructure se case with consideration of TLCP

Key Data	Information Requirements Matrix (Infrastructure)
Use Case	Position of road alignment
Milestone	Preliminary Design to Conceptual Design
Objects	LOG: Geology, hydrography data, environmental constraints, protected areas details, As-is information, information from previous phases (As-is, Feasibility, alternative variations) LOI: Weather data, socio-economic aspects related information, cost-time analysis, infrastructure and utilities, national standards and guidelines, material details, construction phase considerations DOC: Explanatory report, soil report, construction phase line report, safety report
Actors	From Preliminary Design (Who delivers): Owner (Public/Private), Legal& state bodies such as state-approved surveying and information department, specialist/consultant, Fire protection expert, energy suppliers In Conceptual Design (Who requires): Planners, Owners, state authority, civic bodies, energy suppliers

By defining appropriate LOIN use cases adhering to DIN EN 17412-1 (DIN e.V., 2023), TLCP establishes an organized information delivery system for inter-project phase processes, thereby minimizing the risk of unnecessary iteration loops and information gaps. The forthcoming dissemination of LOIN use cases through web-based platforms will adhere to established requirements, foster interdisciplinary collaboration, and ensure consistent scrutiny of information delivery procedures, which are both integral to sustainable project management objectives.

In summary, the Total Life Cycle Process (TLCP) emerges as a fundamental framework for seamlessly integrating sustainability considerations into project management practices within the Architecture, Engineering, and Construction (AEC) industry. By facilitating efficient information management, fostering collaboration, and enabling informed decision-making, TLCP empowers stakeholders to navigate the intricacies of complex project lifecycles while upholding sustainable principles. This comprehensive approach not only ensures the development of environmentally responsible projects but also contributes to the creation of socially beneficial built environments.

Looking ahead, the forthcoming web-based dissemination of Level of Information Need (LOIN) use cases represents a significant advancement in enhancing information exchange efficiency within the AEC sector. Through TLCP, this initiative not only enhances the precision of information delivery but also encourages interdisciplinary collaboration across project phases. By leveraging

systematic derivation of Information Requirements, cross-phase methodology, agile transition, process optimization, and fostering discussion and exploration.

In the course of the study, it emerged that various approaches have developed in the different phases, which require different information requirements. One example from infrastructure planning depicted in Table 2 is that the information from the planning phase must be prepared in such a way that authorisation is possible based on the applicable technical and legal requirements.

Efficient integration of the TLCP process requires a meticulous consideration of not only the primary criteria for information requirements but also the often-overlooked sub-criteria and sub-sub-criteria. Failure to inspect these finer details can result in significant time loss. By adopting this comprehensive approach, TLCP has the potential to evolve beyond a mere project standard to become a standardized practice within the entire organization. This shift ensures a thorough and consistent application of TLCP principles, enhancing overall efficiency and effectiveness across diverse projects and initiatives.

Implementation and integration of TLCP in a web-based information modelling tool

Implementing and integrating life cycle processes in a web-based information-modelling tool is achieved following the steps shown in the process picture (Figure 3) below:

The first step towards implementation of TLCP in a web-based information modelling tool involves identifying and defining all the life cycle processes that are relevant to the project, tailor-made for each life cycle phase, such as preliminary, conceptual, and detailed design, construction, maintenance, renovation, and demolition, among others. In this step, as listed in Table 2, the impacts, input and output, object types and actors with all inter- and outer relations must be defined in data and rule catalogues. Once the processes have been defined, they are to be modelled in the information modelling tools. After this stage, the data and information throughout the entire life cycle of the project would typically look like various islands, which in some cases are connected, and, in some cases, not, in which the data and information flow is not guaranteed during the entire life cycle.

The next step is to establish connections between the different processes. This is typically done through a process flow diagram or a similar tool that shows how the processes interact with each other and with the building model in so-called process catalogues.

Therefore, in the next step, an integration platform should be designed to establish integration between different systems, such as project management systems or cost estimation tools for additional functionality. Web-based platforms are one of the best examples of such smart services in which nested information can be kept, interconnected and analysed based on integration catalogues.

Such web-based information modelling environments are from one side capable of parsing data and models, and interlinking information, and from the other side connect them to resources from manpower to machinery and collaboration between human and technology using Artificial Intelligence (AI) methods. By establishing such connections between various sources, a comprehensive overview of the project lifecycle not only in the planning and design stages but also in the construction, operation and maintenance is ensured. Once the integration platform is set, different layouts can be designed to host the query and filter catalogues and apply them to the nested information based on the profile specs along phases or in the transition processes. These layouts define which data are to be shared with whom and when based on what expectations and with which results. Thus, information sharing between stakeholders and parties involved in the project is in a targeted way so that process-oriented information flow, collaboration and relevant communication is guaranteed. Such layouts can be purposed to target design, construction, operation and maintenance processes; transition processes; machine, human, and technology processes; or sustainability processes. The smart platforms have the capability to keep the information regularly updated and maintained to reflect changes over time with versioning and archiving mechanisms which is crucial especially in the operation, maintenance or renovation processes

In conclusion implementing and integrating TLCP in a web-based information modelling tool improves collaboration, provides more efficient processes, and better management of the project over its entire life cycle.

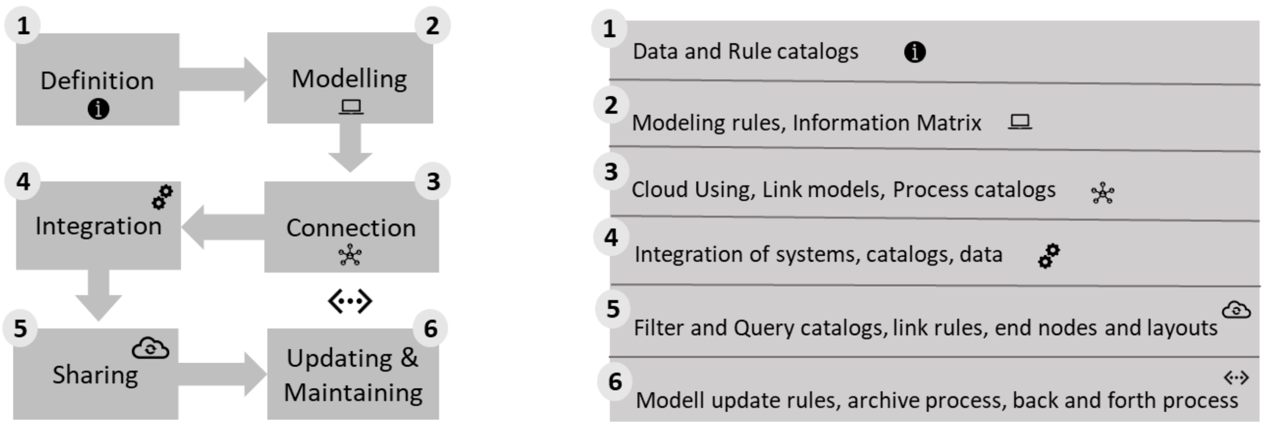

Figure 3: Integration of TLCP in a web-based information-modelling tool

Conclusions and Outlook

The integration of different data sources and information models based on the TLCP is essential to increase efficiency and ultimately promote sustainability in construction. The information management applied enables systematic, evidence-based decision making across the design, construction and management domains, ensuring seamless data exchange and communication between the various project stakeholders across all phases. To improve the flow of information and ensure system interoperability, industry players need to collaborate more and establish common standards and data exchange formats. One promising option is the incorporation of artificial intelligence and machine learning, which could provide the potential for automating analysis and decision support systems in the future. Further research and pilot studies, as well as more widespread use in practice, will drive the development of this methodology and increase its usefulness and practicality.

DEVELOPMENT OF A PROCESS MODEL-BASED TOOL FOR CIRCULAR CONSTRUCTION SUPPLY CHAIN INTEGRATION

Lu Ding[1], Tong Wang[1], Wim Gielingh [2], and Paul Chan[1]
[1]Delft University of Technology, Delft, NL
[2]Real Capital Systems B.V., Nijkerk, NL

Abstract

The recent research focus on circular construction supply chains challenges the integration of supply chain processes. There is a need to build simulation tools for construction, facility management, deconstruction and reuse of building components. This paper introduces a model-based tool to enhance supply chain process integration developed with Business Process Mapping and Notation (BPMN). The model captures the remanufacturing supply chain for façade products that are demounted and reapplied in a different construction project. The paper highlights the tool's potential for predictive analysis and decision support based on supply chain performances. The demonstration shows an innovative approach to CE-driven supply chains.

Introduction

The construction industry is gradually adopting the concept of circular economy (CE) as one of the major transitional goals to reduce greenhouse gas emissions and waste throughout the full building life cycle. Many recent studies have reached a consensus that supply chain wide innovation is a prerequisite for this transition, as well as a focused research agenda for this topic in construction (Akinade and Oyedele 2019; Migliore 2019; Nasir et al. 2017). Construction supply chain management (CSCM), a field of research and practice that has been active for several decades, was introduced because of the growing demand of efficient construction processes and lessons learned from LEAN manufacturing (Eriksson 2010; O'Brien, London, and Vrijhoef 2002). In the background of CE, more studies have revealed strong interest in developing more circular and closed-loop construction supply chains (Adi Wijaya and Armyn Machfudiyanto 2023; Akinade and Oyedele 2019; Incorvaja et al. 2022).

Managing and coordinating construction supply chains is an ambitious task given its 'complex', 'project-based', 'fragmented' and 'contingent' nature (Koolwijk et al. 2018; Koskela, Vrijhoef, and Dana Broft 2020; Vrijhoef and Koskela 2000). Hence, supply chain modelling could provide support for the simulation evaluation, monitoring and prediction of processes (Cheng et al. 2010; O'Brien, London, and Vrijhoef 2004). Considering that CSCM is a vast subject that has been explored by multiple disciplines from various perspectives, it is difficult to find a single model that serves all needs. Both highly abstract mathematical models and more realistic simulation models have been extensively used for the purpose of analysis and optimization in CSCM (Chen and Hammad 2023). As the new digital systems such as digital twins are further developed, more integrated models and applied tools have been proposed to depict the complex supply chain networks and business processes (Cheng et al. 2010; Neuhäuser et al. 2023). Besides, there is also a clear trend of developing CSCM models for sustainability and CE related objectives. Recently, scholars have particularly highlighted the lack of models that integrate the R strategies such as reuse, recycling and remanufacturing (Chen, Feng, and Garcia de Soto 2022; Chen and Hammad 2023; Hussein et al. 2021). Despite that many studies have already addressed various types supply chain models for different challenges of CSCM, they are in most cases based on linear economy scenarios, characterized by forward flows of products and materials. What is missing, is the modelling of circular construction supply chain operations, that, according to the literature review by Ding, Wang, and Chan (2023), shall involve reverse logistics (RL) and process integration of both forward and reverse flows.

To expand knowledge and practices in modelling circular CSCM operations, this study proposes a process centric supply chain model that represents the remanufacturing supply chain for construction products. The model partially captures and simulates the complex remanufacturing procedures in the circular supply chain of recovered construction products. In the project case, wooden frame window and door components are recovered from one demolition site and remanufactured into new façade elements for another construction site in the city of Amsterdam. The framework of Supply Chain Operations Reference Model (SCOR) is used as the core structure to model and elaborate the supply chain processes and performance indicators. And further, the business process model and notation (BPMN) language is utilized to transform the supply chain processes with more detail levels into a digital representation with the potential to build executable software with the Camunda API. A demonstration tool is designed to be accessed by different supply chain stakeholders to interact with input/ output data and gain more insights for critical decision-making.

Theoretical Base for Modelling

Modelling Supply Chain Integration for CE

The efficiency of reverse supply chains can be improved by standardizing processes and procedures, even when the buildings an components are entirely different, and even when the disciplines involved are different. This may bring more commitment and capacities from the supply chain to CE (Koolwijk et al. 2018; Teixeira and Borsato 2019). It is particularly challenging for CE oriented construction projects, given that most of these projects are still experimental pilots There is limited evidence that such practices could be repeated at greater scales. Thus supply chain integration templates for circular projects, that support repeatable processes and continuous improvement, will be highly relevant for tackling the challenges of CE in construction.

A number of studies in the field of supply chain management connected the concept of supply chain integration with the maturity of business processes (Lockamy and McCormack 2004; Trkman et al. 2007). In these frameworks, the more 'mature' supply chain processes evolve from 'Ad Hoc' business operations, where processes are not well documented or structured, to more integrated and standardized processes. The collaboration between companies improves. More repeatable and predictable procedures are set up to reduce overall costs. The model in Figure 1 by Lockamy and McCormack (2004) defines the maturity of supply chain processes in five levels based on the reference to the key supply chain processes defined in the Supply Chain Operations Reference model (SCOR). SCOR is one of the most commonly applied standards to map supply chain configurations and processes (Teixeira and Borsato 2019). The framework defines the following distinctive processes in the supply chain: plan, source, make, deliver, and return. The SCOR features a hierarchical structure of processes, which consists of four levels of detail in process descriptions. The framework provides an appropriate starting point for practitioners to define the key business processes and sub-processes in a supply chain system (Supply Chain Council (SCC) 2017).

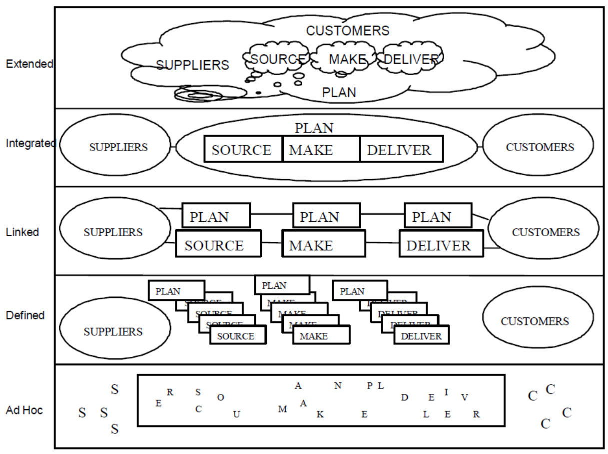

Figure 1: supply chain process maturity model, source: (Lockamy and McCormack 2004)

It would be a rather new experiment to utilize the theory of supply chain process maturity model and SCOR for CE driven initiatives, but there is clearly already a growing discussion on the potential of supply chain integration in circular and sustainable transition. Di Maria, De Marchi, and Galeazzo highlighted that the integration enabled by industry 4.0 technologies such as smart manufacturing play an mediation role for CE performance, because the enhanced links between actors in the supply chain positively affects the utilization of resources in a circular manner (2022). Similar conclusions are drawn by studies in the construction industry, addressing needs for integrating supply chain and logistics processes for the goal of CE in construction projects (Chen et al. 2022; Incorvaja et al. 2022). Modelling the processes of integrated supply chains will be a prerequisite for achieving industrialized CE.

Performance Goals for Circular CSCM

The Ellen MacArthur foundation (Ellen MacArthur Foundation 2013) makes a distinction between the technical cycle, which includes materials that have to be maintained and reprocessed as much as possible as part of a finite material stock, and the biological cycle that may be regenerated by the biosphere. In principle, circular supply chain management for the construction sector will incorporate both loops and should integrate forward and reverse flows of products and services in the full building life cycle (Ding et al. 2023; Farooque et al. 2019). In the ideal condition, a circular supply chain will require the minimum amount of primary resources for production and output zero waste, emissions or hazardous materials (Farooque et al. 2019). However, the more realistic goal definition of circular CSCM will be based on current frameworks of CE and CSCM concepts, that is to systematically integrate CE thinking and R-ladder strategies, such as recycling, remanufacturing and reusing, into the management of resources in construction supply chains, which involves all stakeholders in the construction project life cycle, including construction organizations, manufacturers and waste management agencies (Chen et al. 2022; Ding et al. 2023; Farooque et al. 2019).

The SCOR standard defines 5 main performance attributes: reliability, responsiveness, agility, costs and asset management efficiency. The standard also elaborates more performance metrics and best practices to describe and measure performance both quantitatively and qualitatively. Part of the performance aspects of SCOR already aligns with the performance goals of CE. Especially the cost and asset allocation performance is critical to circular CSCM, because currently the more desired strategies of reuse and remanufacturing of construction products are often hindered by higher material handling cost and increased logistics cost and mismatch between the moments of materials supply and demand. Therefore, in the current context of CE transition, it is reasonable to refer to the SCOR defined performance indicators and prioritize the cost performance while modelling circular construction supply chain processes, hereof the urgent practical goal is that more circular strategies may become more competitive while positioned against traditional linear supply chains.

BPMN

There are multiple ways to model business processes in a supply chain system. Languages such as BPMN and IDEF0 are upon those common standards used for business process management. BPMN is the de facto method for modelling supply chain processes due to its clear logic and visual capabilities. The language is also available in a number of commercial and open source software platforms for customizable development. The combination of SCOR and BPMN has been used by a few previous studies in the manufacturing industry for supply chain modelling (Cheng et al. 2010; Teixeira and Borsato 2019), where the potential to create dynamic and interactive models which industrial participants can understand is demonstrated.

BPMN models of the supply chain system could be approached in different configurations based on how organizational relationships are modelled. The BPMN orchestration model is the basic form that contains a single point of coordination. A collaboration model treats all processes as internal and focuses on only message flows between organizations for inter-organizational processes. The choreography model is designed to highlight interactions between organizations in contrast to internal processes (Eisner 2021). The purpose of modelling for the supply chain determines the method used in BPMN.

Model Construction

This paper proposes an explorative approach to model circular construction supply chain processes, based on demonstration cases of façade element remanufacturing. A few completed construction projects in the Netherlands already demonstrated as pilot projects to recover secondary building façade components and remanufacturer them into new building components in other projects. Based on informal interviews and workshops with the Dutch façade industry stakeholders, some key configurations of the processes are captured for this model. For the purpose of demonstrating the applicability of the model, one pilot case of façade element remanufacturing is used as an example. The case consists of two building sites, project A is a demolition site located in Amsterdam, from which wooden and glass elements from windows and doors have been demounted and then disassembled in factories to be made into new doors and windows for construction project B, which is at another location in the city. Because the part of the project related data is internal for the companies, some assumptions based on the interview and workshops and generated numerical data is used to deliver the proof of concept for the modelling and simulation process as shown in Figure 2.

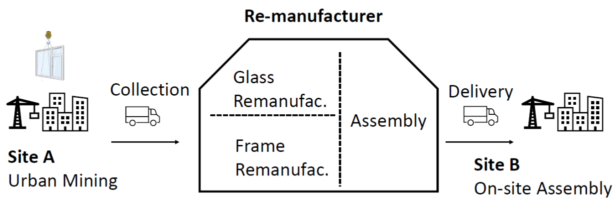

Figure 2: Illustration of the re-manufacturing supply chain

The hierarchical process model defined by SCOR 12.0 is used as the guiding standard for the modelling procedures as shown in Figure 3 (Supply Chain Council (SCC) 2017). The top-level supply chain configuration is modelled to the detail level 1 and 2 defined by SCOR to describe the supply chain actors' goals, responsibilities and process categories. For each actor or stage, key supply chain processes and sub-processes are modelled to the detail level 3 and 4 defined by SCOR and to be ultimately represented in executable BPMN models which could be used to monitor, improve or simulate supply chain processes and performances.

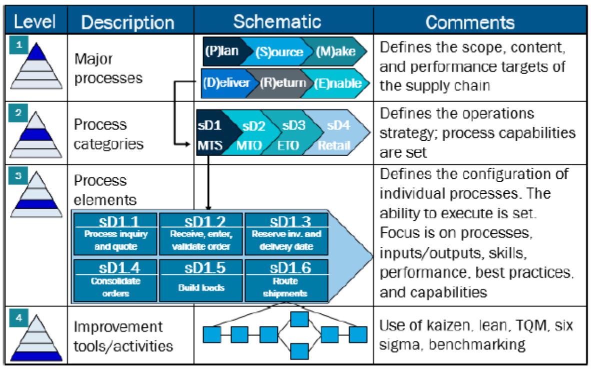

Figure 3: Hierarchical process model defined by SCOR
Source: (Supply Chain Council (SCC) 2017)

Furthermore, to incorporate the performance aspect of the supply chain model, several items from SCOR are chosen to be integrated into the supply chain processes as performance goals for the modelled system. As it will be too complex to implement all performance factors of the SCOR standard, only some of the cost and other matrix related to sourcing and delivery of products and the practice of just-in-time production (JIT) are included in this demonstration model. The reason to emphasize those aspects is that the cases from the pilot project particularly highlighted the challenges of the mismatch between the moments in demolition and construction projects and the increased cost and risk factors due to the increased logistics operations for remanufacturing. The performance indicators are embedded into the BPMN task elements for the evaluation stage of the project. Table 1 shows examples of the performance indicators, selected from SCOR 12.0, to be considered in this demonstration model.

Table1: Performance indicators taken from SCOR

SCOR	Name	Parameters
CO.3.16	Cost to Source Return	On-site treatment and storage cost
CO.3.17	Cost to Deliver Return	Reverse logistics cost to remanufacturer
CO.3.15	Order Delivery Cost	Transportation to construction site
BP.1.10	JIT production	Time of warehousing for products
…	…	…

As the core back-end structure of the model is defined in BPMN, the processes, tasks and required input/output resources are carefully modelled according to the structure defined by SCOR. For the Level 1&2 model, the supply chain for the remanufacturing process consists of four main stakeholders, the project coordinator (often the main contractor), the demolition contractor (urban miner) for project A, the remanufacturer (factory) and the building contractor for the new project B. In this case, the main configuration of the supply chain processes includes project planning, conducting urban mining, delivery to remanufacturer, remanufacturing, delivery to construction site, installation on site. For the Level 3&4 model, sub-processes are created as BPMN tasks to be assigned to the supply chain actors and are detailed for specific operations. The BPMN orchestration model is used to connect the tasks and information flows between different actors. As the remanufacturing supply chain follows a sequential order and the different actors are coordinated as sub-processes of a single project, the model type is suitable for demonstrating the overall supply chain configuration.

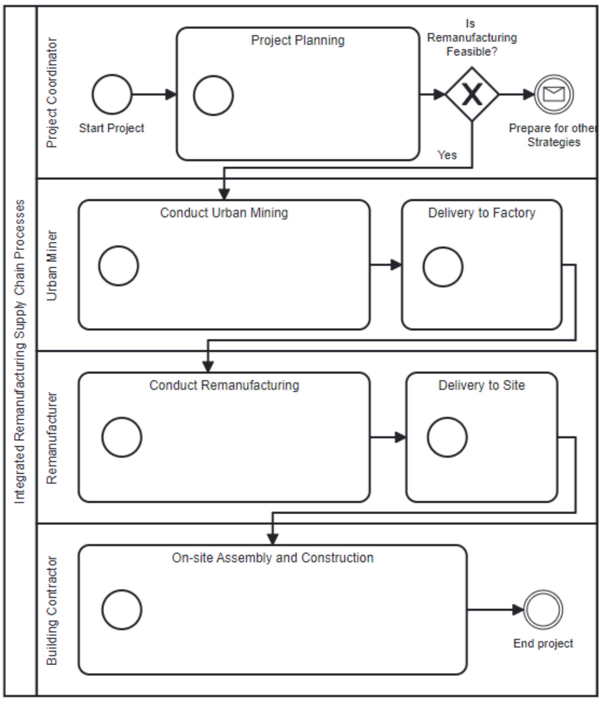

Figure 4: illustration of the main task flows in BPMN

Figure 4 illustrates how the three actors who are responsible for the production processes are controlled by a single point of coordination, which is in this case, the main contractor. Nevertheless, the orchestration model is not fully representative of the real timeline of production. as the four main actors conduct their activities simultaneously and the spatial-temporal coordination between those actors is much more complex than the diagram shows. In this study, the inter-organizational communication between the detailed sub-processes is left out for simplification. The main actors and key processes shown in this overall process diagram is a representation of the detail level 1&2 SCOR process model. The intent wasn't to strictly adhere to the pattern of SCOR for all detailed process definitions but instead to leverage the method and its principles to showcase a proof of concept in remanufacturing operations.

Based on the abovementioned supply chain structures, main process configurations and performance indicators the final BPMN model with detailed sub-tasks is done using Camunda modeler. By using the Camunda API for development, it is possible to attach forms or back-end JAVA classes to certain categories of tasks in the model. Thereby, the supply chain actors are given the possibility to interact with the model through input/output parameters and pre-defined calculations based on the data. Furthermore, the process model could also be executed via the "Deploy" icon within the Camunda portal, and to be accessed by actors through the task list in a web portal interface. More possibilities are allowed by the software architecture of the Camunda API as shown in the diagram Figure 5.

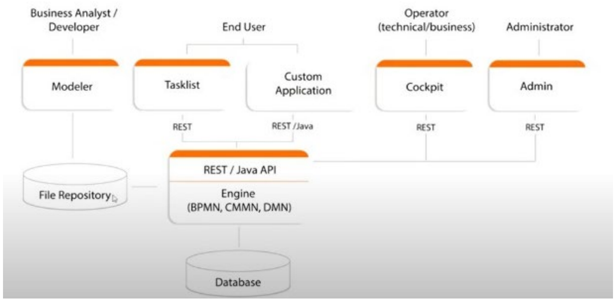

Figure 5: Camunda software architecture, source: (Techbuzz Blog 2022)

Results and Discussion

In this demonstration case, the project-based process of remanufacturing of wooden and glass façade elements is used as both the reference to model the supply chain structure, and also as the application example for potential model utilization. A process-centric model based on the real case is made because most supply chain models without real-world reference will be often quite abstract and could not possibly depict the complexity of processes involving multiple actors and dynamics in CE driven construction activities. On the other hand, the remanufacturing of building products is becoming a more popular and repeated practice in the Dutch construction industry, and the model could potentially be a reference model for other projects similar to the selected case.

Therefore the model is both case-informed and industry-wide generalizable.

The model demonstrates how the circular CSCM operations are modelled as a process based supply chain to achieve more 'maturity' in the form of an integrated supply chain system. The modelling procedure is based on the SCOR standard and BPMN. The execution of the BPMN process is done using the Camunda API which enables web-based user interfaces (UI). It could be accessed by different supply chain stakeholders to create input information and get insights into the supply chain operations in real time. The screenshot in Figure 6 shows how the stakeholders' can login the UI to get access to the executed processes and how the coordinator starts the BPMN process in his/her own dashboard. Despite incorporating limited quantitative data from the real project, the model comprehensively captures the processes for remanufacturing of the construction products in the case.

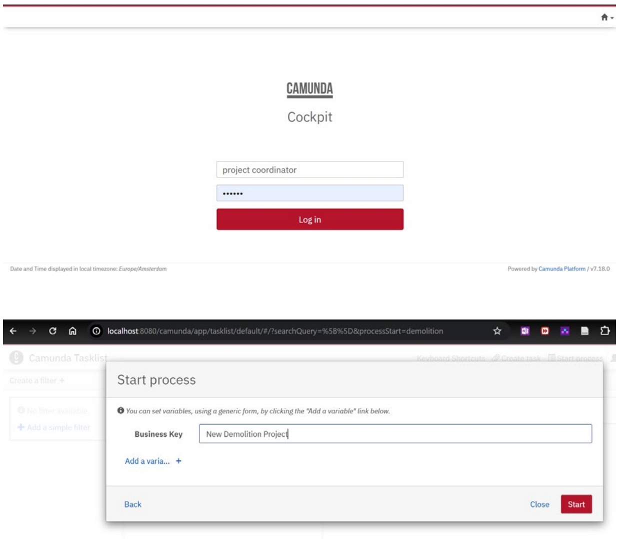

Figure 6: screenshots of the login page and start process

Afterwards, the integration of task parameters and performance indicators is enabled in this model through the Camunda API. This is achieved by creating forms in the Camunda web portal that gets input of variables for the setting of parameters of the model. For example, the transportation distance between the demolition project site, the manufacturer and the new project site; as well as the storage capacity for the locations. Those spatial and resource factors are required to make informative logistics planning between the project sites. As the new construction project may start much later than the deconstruction of the old building, the temporal dimension within the model is also crucial. Whether the schedule of different projects could fit into the resource planning, will drastically influence the performance outcomes such as JIT production and logistics cost. Therefore, the scheduled time of deconstruction, remanufacturing and new construction, are also included as model data and are acquired by the coordinator when initiating the projects. In this way, the model could already provide assumptions of logistics cost and JIT performance scores before going through the other processes. This demonstrates the prediction and simulation potential of the BPMN model that supports decision making before the execution of real processes. With the models and defined tasks, actors, and forms in place, the process can be "deployed" through the web portal. Beginning at the portal's "Start the Project" option, execution aligns with the process model.

In this demonstration case, the coordinator is able to check the feasibility of remanufacturing based on the basic input data about the project, while feasible, the process will be continued to initiate the multi-actor coordination for remanufacturing processes. In this model, the different actors will conduct detailed operations of the sub-processes that are pre-defined in the BPMN. Figure 7 shows screenshots of part of the executable BPMN model with embedded feasibility check for the selected R strategy, Arrow a highlights the tasks where the coordinator put in plannings and get results for feasibility simulation. Arrow b highlights the form interface for step by step data input of logistics information. Arrow c highlights the demonstration results as decision support reference for continuing the remanufacturing processes. In this model, the estimated cost to conduct RL of recovered products and deliver the new products, as well as the score for JIT production (logistics resource utilization) is calculated. The design intention of the model based tool is that the model could then integrate the different actor's detailed operational data and provide more accurate assumptions of the performance in real project timeline. However, as this study is a conceptual demonstration, the functions are not fully detailed to be tested in real projects. Different functionalities that are demonstrated in this study, and possible future development directions are listed in Table 2.

Table 2: Covered functionalities by the tool and progress of development by this study

Functionality & Applications	Progress
Standardize supply chain models of CE strategies in construction with SCOR	Demonstrated
Model supply chain processes in easy-to-understand manner (BPMN)	Demonstrated
Represent integration of different actors in the supply chain system	Demonstrated
Simulate supply chain cost and JIT delivery possibility	Partial Demo.
Allow actors to input and gain key data for model update	Partial Demo.
Simulate and compare performance of different CE strategies (e.g. reuse vs. remanufacturing)	To be Developed
Simulate different configurations of as-is and to-be models	To be Developed

The demonstration of the tool suggest multiple potential areas to apply the model-based tool to CE-driven construction activities incorporating the simulation and predictive capabilities: (1) to improve cost and planning of different CE strategies and reverse logistics operations by including the detailed process cost and time predictions in the task elements in BPMN. (2) to compare as-is and to-be scenarios when designing supply chain re-configuration (Trkman et al. 2007). (3) to continuously monitor supply chain performance by collecting key performance data from more projects where the tool is used.

centric approach brings the model one step closer to real life applications, because it brings more ease of interaction between stakeholders and the model through a process-automation software platform that executes the process model to refined details. This study has selected the commercial software Camunda platform for development and demonstration, similar tools are also

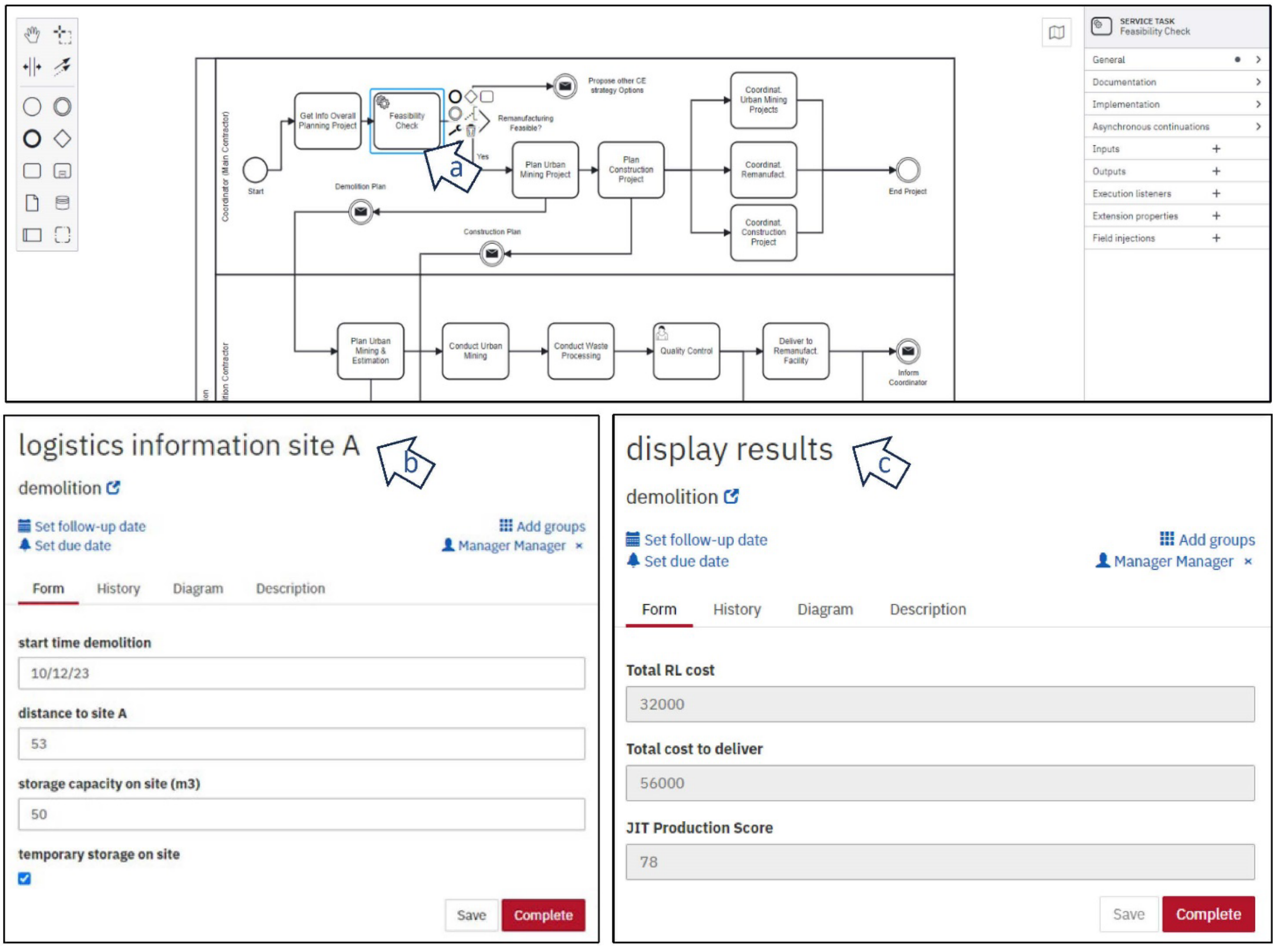

Figure 7: Example BPMN process diagram and the UI for input/ output data

Through post design workshops with experts in construction management from higher education, technical specialists from façade manufacturing companies and consultants for information systems, the tool for process centric supply chain modelling is further evaluated. The innovative approach and potential usefulness of the process simulation and execution tool for CE driven goals have been acknowledged by the potential users. The experts also highlighted that the feature of including cost estimation and monitoring in BPMN will be useful for making more informed decisions about CE in construction. More desired features could be added in the future to the model such as LCA / environmental impact of the processes.

The tool provides the simplicity of having supply chain stakeholders involved to have access to the processes, tasks and relevant parameters in one user interface (UI) that is executed with the BPMN. Compared to other methods to model supply chain operations, this process-available such as Bonita Soft or Eclipse.

One clear limitation of this study is that it is based on tools and standards previously applied mainly to manufacturing, which contains many features that are complex to apply to the project-based supply chain systems in the construction industry and circular economy. And further, the compatibility of the models with the different CE concepts and strategies is also limited. Moreover, the supply chain model tackles only one R-strategy of CE in practice. The more ambitious visions of CE driven supply chain models that may incorporate multiple R strategies are yet to be developed and tested.

Conclusions

The study proposes a process centric circular supply chain model for construction products based on the concept of process maturity in supply chain integration (supported by the SCOR standard) and the BPMN modelling language. It is a proof of concept to demonstrate how such models may act as new tools to improve supply chain integration for CE driven strategies in construction. In this case, the project case of remanufacturing façade elements is taken for the demonstration of their capability to coordinate supply chain operations beyond traditional construction and contractor-supplier coordination.

The model aims to capture the details of the remanufacturing supply chain for construction products, focusing on wooden frame and glass components recovered from a demolition site which are repurposed for a new project in Amsterdam. Four main actors are involved in the modelled case, the coordinator, the demolition contractor for the old building, the remanufacturer and the builder of the new project. For each actor, key supply chain processes and sub-processes are modelled according to the four hierarchies structure defined by SCOR and translated in BPMN for digital representation. Performance metrics such as JIT production and logistics costs from SCOR are integrated in the evaluation matrix for the supply chain model. Afterwards, the BPMN based model is then further developed into a tool for the design of supply chain collaboration, with a web-based interface using the Camunda platform. Through Camunda API, the model enables execution of BPMN tasks and allows for model deployment through a web portal for easy access by supply chain actors. It demonstrates the exchange between supply chain actors and the process model through a range of forms and parameters. Besides, the tool emphasizes the model's predictive and simulation potential, aiding key decision-making points before actual process execution. The study shows how process models are able to capture the complexities of interaction between demolition, remanufacturing and re-construction projects in CE, which traditional CSCM models and tools have not yet effectively addressed. Additionally, the interactive UI developed with Camunda API in this case, shows more multi-stakeholder decision support and collaboration possibilities beyond the process model itself, that may potentially accelerate the adoption of CE strategies by supply chain actors and help in upscaling the practices with more empirical evidence in future cases.

The key innovative feature of the tool is that it applies more mature supply chain process models from the manufacturing industry to cases in circular construction, and utilizes the advanced features from a BPMN software for process simulation and execution. The study tackles an important gap in CE and CSCM literature, which is the lack of understanding and experiments on process integration that connects the overall CE initiatives and strategies with the actual outcome of CE performance in construction supply chains. The study contributes to the methodological advancement for future research to explore modeling techniques for circular construction supply chains, highlighting the importance of standardization of supply chain processes and BPMN's suitability for process execution. By introducing a pilot case of façade element remanufacturing also demonstrates the applicability of the proposed framework to more practical situations, which may lead to more repetitive practices of such CE driven strategies in future construction projects.

The current model in this tool is still limited by the lack of more real-world project data to enhance its functions and improve the model configuration to track and predict the performance more accurately. Future works shall focus on elaborating the process models to suit more practical scenarios and further explore the information models and data integration with existing systems which may support more advanced process execution in more complex cases. Moreover, the simulation approaches of the process model shall be further developed to include more CE scenarios and more comprehensive performance indicators such as carbon emissions and environmental impact.

Abstract

This paper introduces a comprehensive Digital Building Logbook (DBL) framework aimed at addressing challenges in managing extensive data generated throughout the lifecycle of modern buildings. The framework establishes a fundamental structure, defining primary valuable data for DBLs to enhance the value of buildings or dwellings. It delineates essential data elements, guides stakeholder prioritization and engagement, and outlines effective storage methods. Additionally, we propose potential applications of the framework in real-world scenarios, extracted from the analysis of existing DBL implementations. This contribution significantly advances the Architecture, Engineering, Construction, and Operation (AECO) sectors by providing a structured approach to DBL development, offering early insights for future implementations.

Introduction

Data is generated at every phase of the building lifecycle, with each phase presenting distinct data requirements (European Commission et al., 2020). Stakeholders naturally seek precise data to address their specific needs at various points in the building lifecycle. However, the AECO sectors traditionally face three technical challenges to perform effective data collection and management within the sector (European Commission et al., 2020).

- The absence of a systematic approach for capturing, storing, analyzing, and organizing valuable data and information, resulting in data loss.
- Fragmented and dispersed data storage across multiple organizations and even departments within the same organization.
- Limitations in the accessibility to and interoperability of the data that is collected and stored by one actor with other stakeholders across the construction market value chain.

Essential data required by the various stakeholders often lacks a centralized repository, and a systematic approach to data collection, organization, and management is absent. Addressing the needs of all stakeholders thus proves to be a challenge. In response, the Digital Building Logbook (DBL) emerges as a proposed solution. As articulated by the European Commission et al. (2020), *"the capturing and maintenance of data and information is the backbone of the DBL."* However, a critical gap persists in understanding what constitutes valuable data for the diverse involved stakeholders. This paper therefore aims to bridge existing knowledge gaps and build a coherent understanding of valuable data in the DBL domain and examine how different stakeholders can engage with that data. The proposed framework adopts the perspective of a local, possibly multi-building, and restricted DBL, emphasizing a constrained data flow and excluding the consideration of national or European databases. The presented framework seeks to establish a versatile DBL capable of accommodating the diverse requirements of various stakeholders rather than being confined to a specific category. Recognizing that stakeholders may possess distinct needs and perspectives on valuable data, this paper endeavours to define valuable data by linking it not directly to stakeholder's needs but rather to indicators outlined in prior studies. These indicators are intended to furnish data or processed data calculations, thereby enhancing the DBL to deliver a multitude of crucial functionalities for all interested stakeholders. Despite this localized focus, the work is forward-looking, aspiring to establish a repository that, while initially limited in scope, is designed to be expansive and interoperable in the near future. Therefore, the main contribution of this article focuses on addressing the gaps that we have identified. To achieve this, the paper will complement the list of indicators proposed in the survey paper by Alonso et al. (2023) with a framework that defines a specific workflow and data flow for a potential DBL framework applicable in various real-world cases. This need constitutes the problem statement of this article. This innovative approach guides our research and aims to provide early insights for implementing DBLs that can adapted to different contexts and enhance their effectiveness in addressing stakeholder needs. In starting the analysis, the subsequent section introduces several recent works around DBLs. Here, particular emphasis is placed on comprehending the present landscape concerning the formulation of DBL frameworks and the comprehension of DBL data. The succeeding sections then present a theoretical framework for storing valuable data in DBLs, beginning with the strategies employed by the authors to elucidate the meaning of valuable data in the context of DBLs, followed by a set of guidelines on how to store this valuable data. The section thereafter presents the hypothetical application and validity of our framework in selected real-world scenarios observed in practice.

Related Works

In the realm of DBLs, literature is relatively nascent, and consequently, frameworks dedicated to DBLs are still in their early stages of development. While the body of work is emerging, several pioneering studies have laid foundational insights into the domain. Within these studies is worth mentioning Malinovec Puček et al. (2023), where the DBL data structures within the context of the EUB SuperHub project are defined. The framework presented in the article aims to provide an essential set of input data throughout a building's life cycle to compute the passport rating across three areas: energy efficiency, sustainability, and smartness; aligning with EU legislation requirements and anticipating future legislation. One considered research is by Mêda et al. (2022), where the authors focused on proposing a process-based framework for DBLs to address the lack of clear conceptualization of DBL processes, data requirements, and stakeholder interactions. The framework is developed using Business Process Modeling Notation (BPMN) flowcharts and aims to support the EU framework for data collection, management, and interoperability.

Our paper aligns itself with the current trajectory of DBL research, seeking to contribute to the existing body of knowledge by tracking and building upon recent advancements in DBL frameworks and their applications. Another notable scientific publication cited in the proposed paper is a comprehensive survey carried out in 2023 (Alonso et al., 2023), which encompasses all publications on the DBL indexed in prominent scientific search engines such as Scopus, Web of Science, and Google Scholar. This work holds significance as it provides a comprehensive overview of the existing studies on the DBL topic at large, also giving a focus on data storage and DBL indicators.

The publications of Gómez-Gil et al. (2022, 2023) were crucial in defining the parameters of valuable data in DBLs. In their series of scientific works, they first analyze the four most developed European DBL models to provide a defined overview to what constructs a DBL —including the identification of the key stakeholders in the DBL and potential user needs, as well as a proposed structure of indicators, data sources and functionalities— to identify gaps for future developments (Gómez-Gil et al., 2022). Their research then progresses to explore the capacities of DBLs as a gateway to link existing national databases in Spain and Italy, further exploring the available data sources and types that can support the services of a DBL (Gómez-Gil et al., 2023).

For a clearer insight into how valuable data can be employed in the services of DBLs, an understanding of what indicators are and how they process data is needed. In their work, Tupenaite et al. (2017) developed an integrated, hierarchically structured system of sustainability indicators that can be used in the sustainability assessments of new residential projects in the Baltic States. Similarly, Møller et al. (2018) developed the Sustainable Tool for Assessment, Planning, Learning, and Engaging (STAPLE) to create a single common method for a comprehensive and inclusive design and building process for sustainable buildings. How the two publications define sustainability indicators was crucial when building the theoretical framework for the proposed paper.

Apart from scientific publications, two recent European studies on DBLs are fundamental to this paper. First is the European tender [1] led by Ecorys et al.. The study aims to develop a common European model for DBLs (1) to promote tools and protocols that ease data use and sharing throughout the construction ecosystem and (2) to implement DBLs in a harmonious and interoperable way across the EU27 Member States. Findings from the project that are of high relevance to this paper include their final report on *Technical Guidelines for Digital Building Logbooks* (Ecorys et al., 2023), where the guidelines on setting up and operating DBLs under a common EU framework are discussed. The other European project referenced in the proposed paper is Demo-BLog [2] led by TU Delft et al.. Short for *Development and Demonstration of Digital Building Logbooks*, Demo-BLog is a Horizon Europe-funded project that seeks to exhibit how DBL data can serve to advance the current evaluation strategies for climate and energy transition implemented at various levels in Europe. Findings from the project that are relevant to this paper include the state-of-play analysis of selected best practices, where the potential role and scope of the DBL, including the central features, as well as data handling and governance issues are explored with stakeholders. The proposed paper combines findings from both literature and ongoing European studies to delve into the specific data elements that should be included in DBLs, how stakeholders should engage with this data, and how the data should be effectively stored and organized. This approach adds depth and specificity to the previous research on DBLs, providing practical guidance for implementing and leveraging DBLs in real-world scenarios.

Defining Valuable Data in DBLs

In the context of this paper, 'valuable' data is defined as essential files derived from different phases of the building or dwelling lifecycle. These files are deemed crucial for storage in a secure repository, as they contain data that can significantly contribute to enhancing specific categories of indicators.

The value of both, data and indicators, lies in their ability to assist in the decision-making processes and facilitate actions aimed at optimizing building performance and sustainability. Due to the dynamicity of the data requirements that the construction sector may have, our list of valuable data does not aim to present a comprehensive compilation of all possible data that can be gathered during the building lifecycle, nor are we excluding any type of data that

[1] See https://www.ecorys.com/case-studies/technical-study-for-the-development-and-implementation-of-digital-building-logbooks-in-the-eu/

[2] See https://demo-blog.eu/ for more information

may become valuable in the future. Our list and definition of valuable data, at this stage, is formed by an analysis of the state of the art, documentation from policymakers, and an examination of commonalities in similar approaches. It aims to provide and present our process of defining what is the valuable data as a foundation that can be used as a reference to characterize the information stored in DBLs. This paper departs from the notion highlighted in the conclusion by Alonso et al. (2023) that a DBL should avoid overlapping with other tools, including Building Information Models (BIMs) or Common Data Environments (CDEs). In essence, BIM focuses on detailed 3D modelling and information management during the building process and a CDE serves as a collaborative platform or centralized digital hub where construction project stakeholders can access, share, and manage any project-related data and documents. In contrast, a DBL encompasses a comprehensive repository of essential files from the entire building lifecycle, offering a secure storage solution and serving as a foundation for diverse stakeholder needs by providing enriched functionalities based on specific indicators. The proposed framework therefore aims to establish a foundational structure that helps to delineate the primary valuable data to be stored within the DBL to positively enhance the value of the building or dwelling based on different stakeholder needs.

In the realm of DBLs, data plays a crucial role in assessing opportunities and challenges across diverse optimization scenarios for buildings and dwellings. The services built around the DBL then process the relevant data to encourage energy renovation by providing relevant information to (1) design renovation roadmaps, (2) carry out maintenance strategies and (3) monitor and assess the decarbonisation progress of the building (Gómez-Gil et al., 2022). Such services are called "functionalities" (European Commission et al., 2020).

There are various functionalities available in DBLs to support optimization practices of buildings, from providing building analysis and status to conducting energy performance assessments (Gómez-Gil et al., 2022). To enable these functionalities, several necessary indicators must be defined.

An indicator refers to a specific metric or measurable value derived from the data collected, output, or processed within the DBL. These indicators are intricately linked to the valuable files stored in the DBL, as the data within these files can be extracted or processed to identify meaningful values. These values, in turn, serve as indicators that provide valuable insights into various aspects of a building's lifecycle.

For example, consider an EPC stored in the DBL. The data within this file, related to a building's energy efficiency, can be processed to calculate indicators such as the energy consumption rate, carbon footprint, or overall energy performance index. These indicators then offer valuable information that can be used to provide functionalities such as energy efficiency recommendations, comparison with industry benchmarks, or compliance checks with environmental standards. In this way, indicators play a crucial role in unlocking diverse functionalities within the DBL, tailored to meet the needs of different stakeholders involved in the building lifecycle.

At the moment, the European Union (EU) does not provide an official list of minimum indicators that should be included in the DBL, and there is no consensus among the existing initiatives and proposals (Gómez-Gil et al., 2023). The role of a DBL can be seen to serve as a database for storing and processing diverse indicators, shedding light on the conditions and status of a building. These indicators are contingent on the type of data collected or available within the DBL, influencing the outputs derived. A range of indicator categories that aligns with the various data types should therefore be integrated into a DBL to offer information about the building that is of value. Based on an analysis of all the scientific publications on the DBL and its indicators in 2023, Alonso et al. (2023) derived nine indicator categories in their survey, as can be seen in Table 1 (see next page).

The identified indicators require various data to provide the functionalities they can support. To ease the identification of the necessary data, the Demo-BLog project developed a data template that also documents the data types, formats, and sources. The template was initially created to identify a common data language and/or categorisation method that can be applied to the five currently operational DBL initiatives studied in the project: **Chimni** that operates in the United Kingdom, **Woningpas** in Flanders, Belgium, **CLÉA** in France, **CAPSA** in Germany and **CIRDAX** in the Netherlands. The data fields identified in this template can thus be seen as the result of studying every functionality and data field employed across the five initiatives studied, with the terms and scope generalised thereafter to encompass the varying approaches into one universal table. In total, Demo BLog identified 79 data fields across the five cases studied that can be considered valuable to a DBL.

However, a practical challenge identified in Demo-BLog is the inconsistencies in the data structure between various data sources. For instance, while all utility providers furnish data on the energy consumption of a building or dwelling, they do so in different formats and methods. Though valuable data is abundant, the absence of a standardized format or scheme to represent the data remains a barrier for DBLs when coordinating with more than one data source. While this may lead to challenges in data organization and interoperability within a DBL, it does not necessarily depreciate the value of the data stored therein. This paper thus sees the need to compile a catalogue of pertinent files and/or documents associated with a building or dwelling, essential for storage within the DBL. These documents should be accessible to various stakeholders or services, facilitating the computation, storage, or retrieval of indicators crucial for building assessment.

As a starting point, the framework initially emphasizes the

Table 1: Indicators categories, indicators role and metrics as identified by Alonso et al. (2023)

Indicator Category	Indicator Role	Indicator Metrics
Building Information Indicators	Measures the efficiency of the building's information management practices	Accuracy, completeness, ease of access, and security of information
Energy Consumption Indicators	Reveals the building's energy usage, aiding in identifying areas for improvement	Energy consumption over time, meter readings, real-time energy usage
Indoor Comfort Indicators	Provides information on indoor environment aspects	Temperature, humidity, air quality, and lighting levels
Maintenance Indicators	Assists in tracking maintenance tasks such as cleaning, HVAC checks, and equipment replacement	Schedules, checklists, real-time maintenance notifications
Occupancy Indicators	Displays the number of people in the building, optimizing energy use and resource allocation	Number of people
Safety Indicators	Offers information on building safety	Fire alarm status, emergency lighting, evacuation routes
Financial Indicators	Shows financial performance	Operating costs, revenue, return on investment
Sustainability Indicators	Provides insights into sustainability performance	Carbon footprint, water usage, waste generation
Smart Readiness Indicators	Reflect a building's "smartness"	Metrics based on a common EU scheme

inclusion of files or documents that inherently contribute value to the DBL and the building or dwelling. The focus is on saving files without immediate data extraction. Each stored file should be associated with a record entity, allowing users to input essential information, for instance, the issued date for an Energy Performance Certificate (EPC). This record entity serves as a dynamic repository, capable of being updated with information extracted from the files or additional services, thus laying the groundwork for diverse functionalities.
In the following, a non-exhaustive list of valuable files/documents is identified for storage purposes in a DBL for future reference, data extraction, or data processing:

- **Baseline Industry Foundation Classes (IFC) Files**: These files contain the foundational information about a building or dwelling in IFC format that can serve as a reference point for subsequent changes or evaluations.

- **Energy Performance Certificates (EPCs)**: EPCs provide a detailed overview of the energy efficiency of a building, indicating its environmental impact and offering insights into potential improvements.

- **Carbon Bill**: This document outlines the carbon footprint associated with the building or dwelling, detailing the carbon emissions generated through its lifecycle.

- **Building Renovation Passport**: A comprehensive record detailing the history of renovations, upgrades, and modifications to the building, offering a holistic view of its evolution.

- **Selected Renovation Scenario IFC Files**: Similar to baseline IFC files, these documents specifically capture information on selected renovation scenarios, providing a targeted perspective on planned changes.

- **Post-Renovation Analysis**: This file contains assessments, data, and analyses conducted after a renovation, offering insights into the impact of the interventions.

- **Facility Management Reports**: Detailed records on facility maintenance, operations, and management activities.

- **Sensor Data Logs**: Selective storage of sensor data in a DBL, focusing on key metrics such as occupancy and temperature that are relevant for building operations and efficiency, rather than comprehensive data like in a digital twin.

- **Fire Alarm System Reports**: Documentation and analysis of the status, functionality, and events related to the fire alarm system within a building.

Table 2 links each of the specified valuable files with the associated indicator categories that are previously outlined. This establishes a direct correlation between the valuable files and the pertinent data they contain that contribute to the indicators, and further, functionalities, within the DBL. Consequently, this connection aligns with the overarching objectives of the DBL, enhancing the overall value proposition for the building or dwelling.
In conclusion, is worth noting that the valuable files outlined in this section do not constitute an exhaustive list of all possible files that can be stored in a DBL. Instead, they

Table 2: *Association of Valuable Files with Indicator Categories. BII = Building Information Indicators, ECI = Energy Consumption Indicators, ICI = Indoor Comfort Indicators, MI = Maintenance Indicators, OI = Occupancy Indicators, SI= Safety Indicators, FI = Financial Indicators, SuI = Sustainability Indicators, SRI = Smart Readiness Indicators*

	BII	ECI	ICI	MI	OI	SI	FI	SuI	SRI
Baseline IFC files	X			X					X
EPC	X						X		
Carbon Bill		X					X	X	
BRP	X							X	
Renovation Scenario IFC	X			X					
Post-Renovation Analysis	X	X		X					
Facility Management Reports				X		X			
Sensor Data Logs		X	X		X				
Fire Alarm System Reports						X			

represent foundational information that is present in real-world scenarios. These files are instrumental in generating valuable data, thereby enhancing the overall value of the building and augmenting the utility of the DBL.

Valuable Data and Stakeholders

Stakeholders along the construction and built environment value chain are essential in gathering, extracting, and processing valuable data intended for storage in the DBL. How this paper defines a DBL stakeholder is grounded on the findings of the study on the development of DBLs in the EU, funded by the European Commission, where five main user groups are defined (Ecorys et al., 2023):

- **Governmental agencies** that need data for evidence-informed policy-making, the issuing of licences and the enforcement of regulation and disaster management. This user group comprises all levels of governance, including national, regional and local levels.
- **Construction companies** need data to obtain and report building-related information during the design and execution phases of a building lifecycle. The sector encompasses various building professionals, including architects, engineers, contractors and real estate developers, and the collaboration between the relevant stakeholders is crucial to identifying the varying data needs and responsibilities.
- **Building owners and users** who need data on their buildings for monitoring, maintenance and necessary interventions. Building owners have an added responsibility to provide direct or indirect access to building information to not only the building users but also to other relevant stakeholders of the DBL.
- **Financial institutions** that need data to perform various analyses on the assets market and its developments, to gain a better understanding of building transactions. Here, increased transparency and data quality provided by the DBL is key.
- **Utility companies** that need data that provides information on the connection of utilities and the analyses on how they are used to provide detailed information with regards to the building use or performance.

To contextualize stakeholders' interests in data types with real-world DBLs, we have compiled a table that correlates each stakeholder group with the valuable data types that can effectively add value for them. This association is derived from the description of the stakeholders' groups and the data commonly used in their activities. Additionally, the table indicates the indicator groups related to each stakeholder group. These associations are detailed in Table 3.

Moving forward, in the subsequent part of this section, we will examine three real-world DBL implementations among the five studied in the Demo-Blog project, as presented in Section *Defining Valuable Data in DBLs*, to explore their operational mechanisms, identify the most valuable data for each, and present realistic use cases that use some valuable data previously identified.

- The **Woningpas** DBL initiative in Flanders, Belgium, is automatically available to building owners, including individuals and housing companies. Owned by four Flemish Government bodies, it aims to enhance energy efficiency in housing stock. Key stakeholders, including government agencies like VEKA and OVAM, collaborate to ensure energy labels meet regional standards. The Energy Performance Certificate (EPC) is a crucial document supporting this goal by providing essential data for planning energy efficiency interventions and continuous improvement efforts in homes.
- The **CLÉA** DBL, owned by Qualitel, emphasizes user-friendliness. It offers an equipment module with user guides and maintenance alerts for HVAC systems. This feature connects building owners with utility companies to ensure home comfort. Facility management reports tracking service changes are vital for this functionality.
- The **CIRDAX** DBL is a commercial digital materials database operating in the Netherlands and Belgium. It catalogues building components and materials obtained through 3D scanning and manual services. Its focus lies in creating a marketplace for secondary materials, connecting demand with supply for building

Table 3: Association of Stakeholder Groups with Indicators and Valuable Data from Table 2

Stakeholders	Indicators	Valuable Data
Governmental Agencies	BII, ECI, MI,Sul, SRI, FI	IFC files, EPC, BRP
Construction Companies	BII, ECI, MI, OI, SI, FI, Sul, SRI	IFC files, EPC, BRP, Renovation scenario IFC, Post renovation analysis, Fire alarm system report
Building owners and users	BII, ECI, ICI, MI, OI, SI, FI, Sul, SRI	All valuable data in table 2
Financial institutions	FI, Sul, SRI	IFC files, EPC, Carbon bills
Utility companies	SI, SRI, BRP	EPC, Facility Management reports

reuse. Key documents like the baseline IFC file, detailing building construction, and the carbon bill, calculating embodied carbon, engage the construction sector in circularity goals by providing crucial data for material reuse and carbon impact assessment.

The examples highlight the importance of considering the unique context of each DBL — including its founding goals, stakeholder domains, and primary target market — when designing and testing data storage, extraction, processing, and transfer methods. Considering the DBL as a tool that can accommodate various perspectives, priorities, and challenges is crucial in this process. With this in mind, the following sections present a framework that could be utilized in these scenarios. Subsequently, in the next section titled *Framework Alignment*, we will illustrate how our framework could be applied to these case examples, leveraging the valuable data previously presented to provide insights to different stakeholder groups.

Data Storage Guidelines

In this section, we anchor our approach in the context of a local DBL. These guidelines are crafted to establish a framework applicable to individual buildings or local DBLs, laying the foundation for potential expansion toward interoperable or national DBLs. Recognizing the dynamic nature of the DBL landscape, our focus is on constructing a framework that leverages existing technologies and data processes, minimizing the costs associated with creating new ones.

The suggested strategy operates under the premise that the DBL functions as a cloud-based solution. Consequently, the data storage for the DBL is also envisioned as cloud-based, ensuring data availability.

Our approach conceives the DBL as a “sink” for data, serving as a central storage repository where building files containing valuable data are stored. Consequently, our approach concentrates on DBLs focused on data archiving and not on having pointers or links to data in external tools. Another important point, crucial for security, is to encrypt every file in the DBL. Access to these encrypted files will be strictly controlled by an access management system, ensuring that only authorized stakeholders can retrieve them. Access can be facilitated through either a user-friendly interface or an Application Programming Interface (API). This solution needs to accommodate three primary types of files: (1) documents and binary data formats, (2) computer-readable data, and (3) key values. By encompassing these categories, we aim to cover the entire spectrum of considered valuable data.

To support these types and formats of data and to be flexible in both formats and semantics, an architecture with a data layer that manages these different options is considered. This layer should allow higher layer components (e.g., the aforementioned semantic analysis) to manage and handle this data, before its presentation to the user.

In this framework, files remain unaltered once uploaded, accompanied by a record detailing vital file characteristics. Stakeholders responsible for uploading, whether users or services, must store this record simultaneously with the file, enabling other services to access files, extract crucial information, and insert it within the record or as an output calculated with that information.

To enhance interoperability, the record entity is intricately linked to one or more files, allowing users or authorized services to systematically append relevant information. To address the absence of a unanimous consensus on defining a clear data structure for DBL data, we propose storing significant files alongside a flexible Record structure. This structure, while inherently flexible and customizable for various needs, should incorporate standardized essential metadata, such as the associated building, upload date, user responsible for the upload, and a log documenting any modifications.

Embedded within this framework, a fundamental entity representing the building or dwelling will encapsulate key information, including address, the number of floors, and other pertinent details. This central entity will serve as the linchpin connecting each record to its associated building. By referencing the building entity in all records, we establish a cohesive structure that facilitates the organization of valuable data and files in a scalable manner. This design choice not only enhances the coherence of the DBL but also contributes to its scalability, accommodating a broad spectrum of building types and configurations.

For instance, imagine a scenario that highlights the flexibility of the record structure within a DBL, particularly with storing a BRP. Stakeholders uploading records have the option to include additional details such as issuance and expiration dates, or they may choose to provide only mandatory information like the associated building. This dynamic structure allows for various use cases and enables modifications to align with semantic model structures.

In essence, our data storage guidelines are rooted in practicality to provide a scalable and adaptable framework that aligns with existing technologies, while simultaneously laying the groundwork for potential future developments.

Framework Alignment

In this section, we will explore the hypothetical application and validity of our framework in the use cases introduced in the *Valuable Data and Stakeholders* section.

Aligned with the proposed framework, the DBL employs a robust data storage strategy. Each file, including the EPC, the facility management report, and the building IFC is encrypted to ensure security. Access is meticulously controlled, permitting only authorized stakeholders – homeowners, government agencies, energy consultants, or service providers – to retrieve these files. Stakeholders can access files through a user-friendly interface or APIs, emphasizing accessibility.

As previously mentioned, to maintain data integrity, uploaded files remain immutable, and stakeholders or applications responsible for uploading the data are required to accompany each file with a dynamically structured record. This record, linked to the file, is populated with metadata providing essential details such as the date of issue or expiry.

Stakeholder engagement is a pivotal aspect. In the **Woningpas** use case, homeowners, responsible for storing documents, enjoy flexibility in contributing additional details to the associated record. Although the identity of the stakeholder uploading the EPC might not be certain, the process remains straightforward, facilitated through either the user interface or APIs. Upon EPC upload, a record entity is created, detailing the associated building, the uploader, and the upload date.

This structured framework facilitates collaboration. Stakeholders with access can download the EPC and utilize it for various calculations. The outputs, which could range from Key Performance Indicators (KPIs) to specific energy values or recommended interventions, can be stored as files with a record linked as the case of valuable data or even only with a record. This process, whether through user interaction or automated APIs, reinforces the scalability and adaptability of the framework, promising future expansions in the DBL landscape.

Within the **CLÉA** scenario, a facility management report is primarily generated by utility companies that provide services and products such as energy provision and HVAC equipment to homes. The collected data, encompassing both their professional insights and meter-recorded utility usage, can be efficiently uploaded to the DBL through APIs or the user interface. The data may take a static form, such as documents containing processed information handed over to homeowners as statements or transaction receipts, effectively serving as the facility management report.

In our DBL framework, for simplicity, we focus on static data uploaded as files, which will not change over time. From this file, key stakeholders can perform calculations to determine when the next services, possibly maintenance tasks or updates, are scheduled to take place. This process, seamlessly integrated into the DBL, aligns with our framework's emphasis on practicality, scalability, and adaptability. It provides a robust foundation for potential expansions in the DBL landscape while ensuring valuable data remains organized and accessible.

Lastly, in the **CIDRAX** scenario, the baseline IFC file stored in the DBL is created collaboratively by stakeholders involved in the construction or renovation processes. The document serves as a comprehensive snapshot of the building's construction, offering a thorough understanding of its structure. It includes intricate details about the type and quantity of materials used, their spatial distribution within the building, and other relevant specifics. The active participation of stakeholders such as architects, material providers, and contractors is thus essential during the construction or renovation stages to ensure the accuracy of this data. This information is then stored in the DBL, making it accessible to authorized stakeholders.

Authorized stakeholders, including companies like CIRDAX, can retrieve this stored baseline IFC file from the DBL. The document becomes a valuable resource for CIRDAX's objective of promoting circular building practices. By analyzing the detailed information within the baseline IFC file, stakeholders can identify the availability of reusable materials, quantification of materials and optimization of construction practices. After identifying this information, it can be incorporated into the DBL as an immutable file, accompanied by a record entity. This ensures accessibility for all stakeholders while being securely stored in a protected repository.

This section lays the groundwork for conceptualizing DBLs as repositories of pertinent information. Starting from such realistic scenarios, derived from empirical observations of the data types already used in real-world DBLs and their purposes, we generalized the processes to establish paradigms on how a DBL should function. This information will be the source for the definition of an architecture and the elaboration of a platform that can be validated by using empirical data and quantitative and qualitative indicators. Qualitative processes such as user satisfaction surveys and stakeholder interviews can provide insights into the usability and effectiveness of the framework. On the quantitative side, metrics such as the average time taken to retrieve information and analysis of API usage patterns, including the frequency and volume of API calls and the data used by different stakeholders, can measure the efficiency and relevance of the data.

In conclusion, the hypothetical application of our proposed framework across diverse real-world use cases demonstrates its robustness, scalability, and adaptability within the dynamic landscape of DBLs. Our emphasis on data security, controlled access, and the integration of dynamic record entities ensures the reliability and integrity of valuable data. Stakeholder engagement remains at the forefront, providing flexibility for various users to contribute and access information through user-friendly interfaces or APIs. The structured framework not only supports current needs, as illustrated in the presented use cases but also promises a foundation for future expansions in the evolving DBL landscape. Through this approach, we aim to facilitate collaboration, enhance data organization, and uphold accessibility, fostering a more effective and sustainable management of building-related information.

Conclusion

Buildings generate increasing amounts of data and information, which end up scattered in disparate databases. This volume and distribution of data lead to difficulties and challenges in making informed decisions based on it. DBLs have emerged as a key solution to bridge these data availability and archiving challenges.

However, not all data is equally important for making decisions during the building life cycle. Plus, there's still no clear agreement on what DBLs should do, what data they need, and how they fit with other construction software.

It is important to recognize that certain aspects, such as the detailed structure, components, and features of the DBL that will implement our framework, require further elaboration and exploration. These areas should be considered as part of future work to enhance the understanding and implementation of DBLs in real-world scenarios. By acknowledging the need for continued research and development in these areas, we aim to contribute to the ongoing advancement of DBL frameworks and their effective utilization in the construction industry.

The analysis done in this article also allows us to identify some research gaps, which will enable us to frame future work. Specific aspects of these research gaps include:

- **An Undefined Criteria for Valuability**: The absence of universally accepted criteria for categorizing data as "valuable" in the context of DBLs. This article has attempted to find some common ground and offer suggestions on this topic.
- **Inconsistencies in Data Structure**: The absence of a standardized format or scheme to represent valuable data, leading to inconsistencies in data organization and challenges in interoperability between different stakeholders.
- **Limited Stakeholder Engagement**: A knowledge gap exists among various stakeholders, including architects, engineers, and maintenance personnel, regarding a standardized approach to systematic data collection and storage.
- **Overlapping and Interoperability Challenges**: The lack of clear differentiation between distinct solutions in the construction ecosystem (e.g. Common Data Environments, Digital Twins, Construction Management Software), what data each manages, processes or stores and how they interoperate.

Our future work is in line with addressing these gaps and defining an optimal architecture to support the data mentioned in the article. This, together with research on ontologies, such as Smart Applications REFerence (SAREF)[3], which can be used to enrich the data, will allow us to design an efficient and adaptable reference DBL, and properly compare and evaluate the available DBLs.

Abstract

Digital Twin technology has revolutionised overseeing newly built structures. This study suggests employing digital twin-based automatic progress monitoring on construction sites, comparing 3D point clouds with their Building Information Modelling to track progress and predict completion. It highlights integrating semi-continuous monitoring with a building's digital twin for efficient construction management. Leveraging precise data enhances understanding and identifies schedule deviations, enabling timely actions. Demonstrated through real-world construction data, visualised Gantt charts showcase its efficacy, offering insights into task status, schedule deviations, and projected completion dates. This underscores digital twin technology's potential to transform construction oversight.

Introduction

Scan-to-BIM provides a comprehensive assessment of the as-built state in the context of performance improvement (Bosché et al., 2015; Drobnyi et al., 2023b, 2024). Despite its impact, laser scanning is somewhat limited to surface recognition, lacking depth in reflecting built element quality (Hoiem et al., 2022). Researchers explore embedded sensing for conditional data assessment (Alizadehsalehi and Yitmen, 2016). Integrating laser scanner technologies and advanced wireless sensors offers opportunities for comprehensive project exploration, enhancing performance control and project management by merging as-planned models with data-capturing reality. Effectively managing vast and complex data for real-time progress monitoring requires an intelligent system continuously learning from various sources, including historical archive data (Boje et al., 2020). IoT technologies and related systems, combined with digital twin and cognitive computing, collect real-time data (Dawood et al., 2020). Visualizing digital data for stakeholders in different project stages is crucial, with XR technologies providing multidimensional perspectives (Alizadehsalehi et al., 2020).

As per the Project Management Body of Knowledge (PMBOK), controlling and monitoring a construction project encompasses processes to oversee progress and performance, identifying areas requiring plan adjustments, and initiating corresponding changes (Guide, 2001). These processes entail measuring progress through inspections (as-built) and comparing it with the project plan (as-planned) to validate predicted performance. The overarching goal of monitoring is to ensure effectively managed results and outputs by measuring and assessing project performance (Lin and Golparvar-Fard, 2020). Measuring work in progress on construction sites is crucial for project management, impacting various aspects such as time, cost, quality, and safety. This task is particularly challenging due to the complexity and interdependency of activities (Arif and Khan, 2021).

Traditional progress tracking practice depends on visual inspections and daily or weekly reports created based on those inspections to ensure that work meets contract specifications and schedule (Golparvar-Fard et al., 2009). These traditional practices are often slow and rely heavily on the inspectors' personal judgment, observational skills, and weekly expert follow-ups with a high probability of complete and accurate reports. Effective monitoring is crucial for project success; however, even the most robust monitoring systems are insufficient if the project is poorly designed or built on flawed assumptions. Building Information Modelling is a digital representation of a building, capturing 3D geometry and semantic descriptions of components (Kim et al., 2020b). The AEC industry-accepted BIM provides a suitable basis for automated construction progress monitoring. It serves three essential purposes: providing as-planned data, as-built data, and enabling their comparison (Machado and Vilela, 2020). As the baseline for construction progress monitoring, BIM binds AEC contract information, facilitates access to geometric data, allows for special visualization of schedules, and manages progress-related information. Recognized as a rich data source, BIM is pivotal for automated project progress monitoring (Kim et al., 2020a). A well-designed BIM model analyses operations in construction, aiding site management, enhancing communication, coordinating contractors, and planning logistics (Kopsida and Brilakis, 2020). While traditional Building Information Modelling (BIM) and construction schedules effectively capture the as-designed and as-planned phases, they inherently lack timely updation of the as-built and as-performed states during construction progression. This deficiency arises due to the static nature of BIM and schedules, which do not dynamically update as construction activities unfold. Construction sites' inherent heterogeneity and temporal dynamics present formidable challenges to accurate progress monitoring.

This paper proposes using DT to monitor the progress of large-scale construction sites. The major contribution is the tight integration of progress monitoring to DT, facilitating timely progress monitoring of a real construction site. The pipeline of the DT-based progress monitoring is as follows: The workers capture laser scans at the site and are passed to the DT platform. Then, the detection

*Corresponding author

model in the platform automatically detects as-built elements and pushes the information generated from raw data to the graph. This will trigger the progress monitor and traverse the graph to get the progress information at the activity level. Here, an activity refers to a grouping of tasks, where each task represents a specific job tied to a particular element on the construction site. We calculate the current status of the progress (on schedule, ahead of schedule, and behind schedule) of each activity and estimate the finished date if the progress is behind schedule. We visualize these results in a Gantt table via a dashboard, which managers can quickly investigate.

Background

In response to these challenges, Digital Twins Construction (DTC) is emerging as a focal point of attention, offering a reliable information source for continuous production planning and adaptive product design throughout the construction lifecycle. However, the successful integration of DTC faces challenges – industry-wide adoption, technical intricacies ensuring the precision and accessibility of data (Sacks et al., 2020). Crucially, DTC should not be perceived merely as an extension of existing tools like BIM but as a transformative approach to construction production management, emphasizing a closed control loop (Sacks et al., 2020). The concept of DTC, coupled with automated data acquisition, establishes a framework for automatic progress monitoring, obviating the limitations of conventional techniques. This study directs readers to a comprehensive exploration of digital twins in construction through a recent review paper authored by (Opoku et al., 2021), providing invaluable insights into the evolving landscape of construction technology and methodologies.

To streamline and enhance the efficiency of progress monitoring processes, the initial step involves identifying newly constructed objects since the last data acquisition. This task is inherently challenging during the construction cycle due to noise, missing data, and local disparities in the position of as-built elements compared to their as-designed counterparts. The proposed solution involves locating instances of the as-designed model within LiDAR data acquired on construction sites. Current state-of-the-art approaches for object detection fall into two primary categories: traditional and deep learning (Chu et al., 2023; Lan et al., 2024). Traditional computer vision algorithms for object detection rely on deterministic procedures involving primitive shape fitting and statistical analysis (Drobnyi et al., 2023a). The most established methods within this category include RANSAC, Hough transform, and region growing. For instance, the efficacy of the Hough transform in detecting pipes within noisy 3D point clouds was demonstrated by (Ahmed et al., 2014). RANSAC-based methods have gained popularity due to their robustness in automatically segmenting building object instances represented by basic shapes such as cuboids and cylinders, enabling the detection of slabs and pipes. (Anagnostopoulos et al., 2016) applied RANSAC to detect wall surfaces, facilitating the reconstruction of rooms from 3D point cloud data (Anagnostopoulos et al., 2016). The second category employs deep learning techniques, with deep neural networks emerging as the predominant method for object detection. Notably, the PointNet architecture, a deep neural network specifically designed for point clouds, was introduced by (Qi et al., 2017). PointNet predicts the class label for each object segment, receiving a cluster of points as input and outputting a category prediction among 13 classes (Chen et al., 2019).

(Hu and Brilakis, 2024) proposed an automatic clustering method to segment the points corresponding to the as-designed instance. The workflow contains (1) Instance descriptor generation, (2) PROSAC (Progressive Sample Consensus) based shape detection, and (3) DBSCAN (Density-Based Spatial Clustering of Applications with Noise) based cluster optimization. The method matches design-intent planar, curved, and linear structural instances in complex scenarios, including (1) the as-built point cloud is noisy with high occlusions and clutter; (2) deviations between as-built instances and as-designed models in terms of position, orientation, and scale; (3) both Manhattan-World and non-Manhattan-World instances.

Methodology

In this work, we develop our progress monitoring method based on a holistic cloud-based Digital Twin Platform (DTP). This platform operates on a structured ontology, facilitating storing both the as-designed and as-built information for every element within a construction site. This platform intricately captures and retains the element-level status of each component present on the construction site. The status information is derived through various DT services, which meticulously process raw 3D point clouds from routine construction site surveys with laser devices. We use a BIM-assisted 3D object detection algorithm to ascertain the presence of each element within the as-built data. Such information is transmitted and systematically stored in the DT platform as element-level status, forming a comprehensive repository of the construction site's dynamic and evolving conditions. By retrieving and processing the information in the DTP, we calculate the activity-level progress status and estimate the finish date of the activity.

Ontology

The pertinent partial ontology for this study is illustrated in Figure 1; the complete ontology can be found in (Schlenger et al., 2022). Construction information is organized within a graph-based database, aligning with the structure defined by the ontology. The ontology bifurcates into as-planned and as-performed segments, encompassing `Work package`, `Activity`, `Task`, and as-designed elements under the as-planned side. In contrast, the as-performed side includes `Construction`, `Operation`, `Action`, and as-built elements. These nodes adhere to a hierarchical

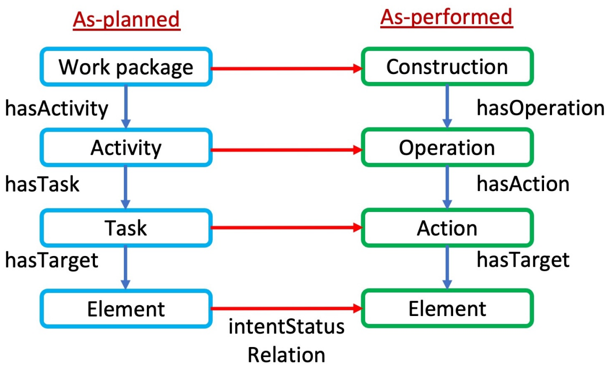

Figure 1: Visualization of a segment of the Digital Twin ontology employed in the progress monitoring pipeline.

order and establish connections through various relationships. Notably, the work package node, functioning as an aggregation of activities, is linked to respective activity nodes through the `hasActivity` relationship. The as-planned and as-performed sides of nodes are connected with `intentStatusRelation`. Recognizing that construction plans often operate at the activity level, the as-planned schedule is stored within the `Activity` node, capturing start and end dates. The schedule reflecting the as-performed activities is archived within the `Operation` node, mirroring the data in the `Activity` node. In instances where no prior surveys have been conducted for the target building, the operation's start date is presumed to align with the as-planned start date. Alternatively, if previous surveys have been undertaken, the operation's start date is designated as the most recent scan date. The conclusion of the operation is determined by extracting the latest update date at the element level. The as-built element node retains the progress at the element level, computed using the BIM-assisted 3D object detection algorithm (Hu and Brilakis, 2024).

Object detection

Automating progress monitoring necessitates the initial step of detecting constructed objects on construction sites, a task burdened with challenges, as outlined in the preceding background section. Streamlining this process requires a global registration between the BIM model and 3D point cloud data. We utilize a global registration method to align the coordinates of the BIM model and LiDAR data (Monasse et al., 2023). This efficient algorithm optimizes global robust energy between two line segments extracted from the BIM and LiDAR data. Once registered, the Region-Of-Interest can be confined to the upscaled bounding box of the query as-designed element, provided the BIM model and LiDAR data share the same coordinate system. This region of interest will be an input to a filtering step to remove clutter, if they exist. Given the geometric richness of the construction environment, we propose a novel solution based on geometric features, with a specific focus on planar polygons as a robust data abstraction. Our method involves detecting and clustering planar polygons in each dataset, followed by a matching step to compare planar polygons within associated clusters. This comparison allows us to identify local discrepancies in position, if they exist, ultimately eliminating false detection. We not only determine if there is a local discrepancy but also calculate the corresponding geometric transformation. This can avoid false positive detection when facing significant local discrepancy.

Integration with DTP

Specific Application Programming Interfaces (APIs) have been developed to facilitate seamless communication with the DTP[1]. These APIs enable the retrieval, creation, and updating of nodes within the DTP. The comprehensive progress monitoring pipeline is visualized in Figure 4. Given the assumption that the DTP is current with both as-built element progress and operation start and end dates, an initial fetch request is initiated to retrieve all `activity` nodes from the DTP. Subsequently, each activity's as-planned start and end dates are extracted from the corresponding `activity` nodes. Following the hierarchical structure, all as-designed element nodes linked to each `activity` node through relationships like `hasTask` and `hasTarget` are retrieved from the DTP. Leveraging the intent-status relation, with `intentStatusRelation` corresponding to the as-built node for each as-designed node is fetched. The element-level as-built progress is then aggregated from the as-built element nodes. Employing reverse relationships with `hasTarget` and `hasAction`, `operation` nodes are fetched, and the associated as-performed schedules are compiled. Once the as-planned schedule, as-performed schedule, and element-level as-built progress are at our disposal, the groundwork is laid for the computation of progress at the activity level.

Progress calculation

The determination of activity status in relation to the schedule is outlined in Table 1. An activity is marked as ahead of schedule if the element-level progress exceeds zero and the end date of the operation precedes the corresponding activity end date. The cumulative assessment considers an activity as ahead of schedule if a majority of its elements exhibit this characteristic. Simultaneously, the percentage of completed tasks within an activity is computed. In the case of an activity falling behind schedule, the maximum delayed task determines the extent of the delay. To further enhance understanding, the calculated percentage of tasks completed, and the determined delay duration are employed to estimate the revised end date using a projection function. Presently, the projection utilizes an S-shaped function, closely resembling actual construction progress (San Cristóbal, 2017).

Results & Discussion

The experimentation encompassed utilising both as-designed data and 3D point cloud data obtained from a

Table 1: Criteria for assessing activity status concerning schedule compliance.

Condition	Decision
Element level progress > 0	
Activity end time > Operation end time	Ahead
Activity end time < Operation end time	Behind
Activity end time = Operation end time	On
Element level progress = 0	
Activity end time > Operation end time	On
Activity end time < Operation end time	Behind
Activity end time = Operation end time	On

construction site located in Spain, as shown in Figure 2. The detection results of columns in shown in Figure 3. As can be seen, our method can detect corresponding elements in the whole point cloud building. The output of the progress monitoring encompasses key metrics, including the percentage of tasks completed, progress status, the number of days ahead or behind the schedule, and the projected completion date for each activity. To enhance the interpretability for construction managers, the results are visually presented in the form of a Gantt chart, as depicted in Figure 5. Gantt charts were chosen due to their widespread usage in construction scheduling, making them a familiar and effective visualization tool for managers. Each activity is graphically represented by two horizontal bars: one reflecting the as-planned schedule and the other the as-performed schedule. The as-planned schedule is denoted by a grey bar, while the as-performed schedule is illustrated with a coloured bar. In the chart, a dark red bar signifies that the activity is complete but was delayed, whereas a dark green bar indicates that the activity is not complete but is on schedule. Light red signifies that the activity is behind schedule and has not yet been initiated, while light green indicates that the activity is on schedule and has yet to commence. The textual information overlaid on the grey bar corresponds to the name of the activity assigned by the construction company. Additionally, text overlaid on the coloured bar details the progress status, the number of days the activity is ahead or behind schedule, and the projected completion time.

Following this, the Key Performance Indicators (KPIs), including the *percentage of tasks delayed per activity* (KPI1) and the *percentage of delay in days per activity* (KPI2), are systematically computed. KPI1 is the quantitative measure obtained by dividing the number of delayed tasks for each activity by the total number of tasks scheduled for that specific activity. This ratio provides a nuanced understanding of the prevalence of task delays within individual activities, contributing valuable insights into the project's task-level performance. Simultaneously, KPI2 is calculated by determining the ratio between the number of de-

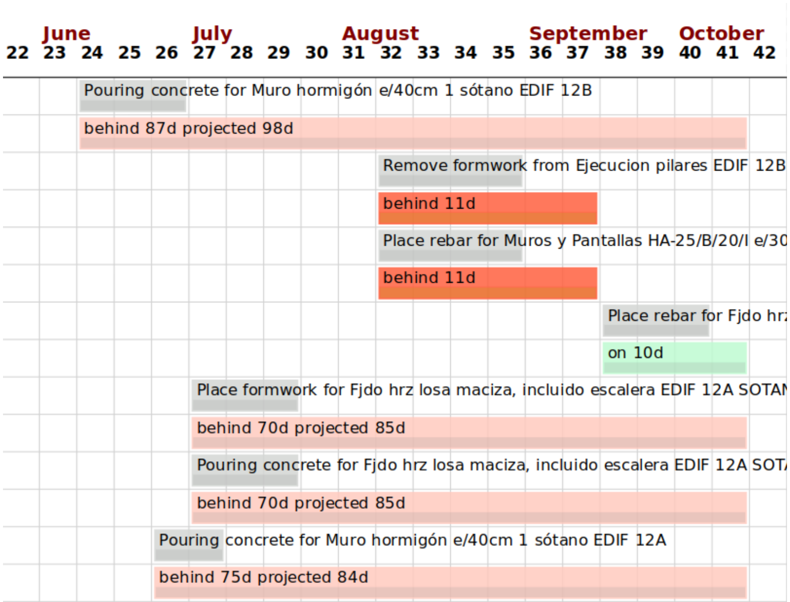

Figure 5: Graphical representation of progress monitoring algorithm output in Gantt chart format for enhanced comprehension

layed days for each activity and the planned duration (as-planned days) for that respective activity. By doing so, KPI2 offers a comprehensive overview of the temporal aspects of project performance, highlighting the extent of delays compared to the initially envisaged project timeline.

These calculated KPIs play a pivotal role in assessing the efficiency and timeliness of project activities. Once computed, the KPI values are securely stored within the DTP, forming an integral part of the platform's repository of project performance data. This centralized storage ensures that historical KPI data is readily available for analysis, comparison, and continuous improvement efforts. Furthermore, to enhance accessibility and visibility, these KPIs are dynamically displayed on the project's dashboard. This strategic placement on the dashboard gives project stakeholders timely, at-a-glance insights into key performance metrics. The dashboard becomes a central hub for monitoring and understanding project delays, fostering a proactive approach to decision-making based on the current project status. The source code for this paper is accessible on GitHub at the following URL: `https://github.com/BIM2TWIN-Team/WP3-progress-monitor`.

As highlighted in a recent comprehensive review on computer vision (CV) aided progress monitoring in construction (Sami Ur Rehman et al., 2022), the conventional progress monitoring methods are characterized by slowness, tediousness, and susceptibility to errors. However, the existing body of literature on CV-based progress monitoring is dispersed across various domains, lacking a cohesive focus on methodologies and processes throughout the entire CV-based progress monitoring workflow. This article addresses this gap by presenting a holistic approach that provides timely information and knowledge through Key Performance Indicators (KPIs). Such data availability is critical, enabling simulations of alternative execution plans that prove invaluable at different construction stages. This capability is instrumental in minimizing delays and optimizing equipment usage, as discussed by Yeung et al. (Yeung et al., 2022). By consolidating insights and methodologies, our approach aims to streamline CV-based progress monitoring into a coherent and efficient process.

Conclusion

This study emphasizes the profound impact of DT technology on monitoring and managing newly constructed buildings. The proposed DT-based method marks a substantial leap in automatic progress monitoring for real-world construction sites. Utilizing scanners to collect 3D point clouds and Digital Twin Platforms (DTP), this approach allows detailed construction status analysis and completion timeline prediction. The seamless integration of semi-continuous monitoring with the building's DT underscores the pivotal role of DT tech in efficient construction management. Leveraging precise data not only enhances project understanding but also enables timely deviation identification, empowering stakeholders to implement corrective actions and proactive strategies, enhancing project efficiency. Extensive real-world experiments validate this method's effectiveness, highlighting DT's potential to transform construction monitoring and foster adaptive project management. As DT continues evolving, its integration into construction processes will be vital for achieving optimal efficiency, accuracy, and proactive decision-making.

HOW CAN DIGITAL TWINS BE USED IN HIGHWAY MAINTENANCE? A QUESTIONNAIRE SURVEY FOR INDUSTRY PRACTITIONERS

Mengtian Yin[1], Varun Kumar Reja[1], Ran Wei[1], Brian Sheil[1], and Ioannis Brilakis[1]
[1]Department of Engineering, University of Cambridge, UK

Abstract

The digital twin (DT) concept can potentially bring about a systematic approach to digitalizing information for road infrastructure systems. However, it is currently unclear how the DT concept can be applied in the highway maintenance domain and what the benefit is. This study conducts a questionnaire survey to explore what industry professionals view as the main obstacles in current practice and what areas of highway maintenance can improve if using a road DT. A total of 183 responses were obtained from highway industry practitioners. The results reveal the main issues in maintenance processes and potential use cases of DTs.

Introduction

Highway infrastructure systems play an essential role in society, the economy, and security. However, with the increasing number of vehicles travelled on the road network, real-world road assets are experiencing rising traffic load and utilization (Sinha, Labi and Agbelie, 2017), causing risks of structural failures. Therefore, maintaining highway assets consistently above a standard level is challenging, requiring a comprehensive acquisition of dynamic road condition data and effective data analytics tools to forecast road states as well as make sound treatment strategies. Unfortunately, highway authorities still heavily rely on manual inspection to assess road condition (Koch *et al.*, 2015) and make treatment plans based on the experience of pavement experts. The entire highway maintenance process may be changed by the newly emerging digital twin (DT) approach, which might enhance data acquisition, integration, analysis, and decision-making in a systematic way.

A DT represents a digital replica of physical assets and processes involved in the built environment lifecycle, enabled by a twin-based system (Brilakis *et al.*, 2019). In the highway maintenance context, DTs provide a detailed virtual model that simulates the behaviour and operations of physical highway infrastructure systems. Based on the dynamic virtual model, DTs bring about a new information management (IM) approach that can potentially improve data interoperability, integration, and analytics. In this way, highway experts may be able to efficiently retrieve useful information from DTs and make more appropriate decisions on maintenance interventions. So far, the DT concept has been widely applied in the fields of aerospace (Li *et al.*, 2021), manufacturing (Kritzinger *et al.*, 2018), and recently gained popularity in building construction (Sacks *et al.*, 2020). However, implementation of DT approach in highway maintenance is still scarce. It is currently unclear how the DT approach can be applied in this area and what actual benefits a DT can provide. Without knowing the purpose of using a DT, it is impractical to build a road DT system with a decisive scope of meta modelling, level of detail (LOD) for model instance generation, and frequency of data updating.

To tackle these issues, this study describes results from a questionnaire survey for highway industry practitioners to understand the main barriers in their professional workflows and the potential improvements that can be realised using a road DT. This questionnaire study is designed based on (a) a state-of-the-art review of DTs in road domain; and (b) interviews of 20 industry experts from the UK National Highways company, which manages England's motorways and major A roads (National Highways, 2021). The survey was further disseminated to highway industry practitioners internationally through different channels, such as email invitations. As a result, 183 valid responses have been obtained from different regions, mainly the UK, China, US, India, and Australia. The survey unveils crucial phases, applications, and use cases that a road DT can potentially take effect on. It also shows how practitioners perceive the challenges of DT deployment in the highway industry.

In the following sections, we first review relevant studies about DTs of road infrastructure. Then, we demonstrate the research methodology before presenting and discussing the survey results. At last, we draw conclusions by summarizing key findings and contributions.

Background research on DTs for road infrastructure

In the planning and design phases, a road DT is mainly used to assess the impacts of new road designs on existing networks and natural environments. Machl et al. (2019) present a DT-based method to assist road planners in assessing design impacts on agricultural core road networks. Jiang et al (2022; 2022a) propose a method to automatically generate DTs of road networks from open map data and use the DT to check the clearance of underpass roads in road widening projects. Jiang et al. (2022b) propose a DT-enabled sustainable urban road planning framework that integrates multi-criteria decision-making and Geographic Information System (GIS), where DTs provide the routes and traffic congestion data.

In the road construction phase, the DT is indirectly used to assess the performance of new road materials. Meza et al. (2021) developed a road DT to examine the use of secondary raw materials (SRM) in real road construction projects. Manually developed road Industry Foundation Classes models are imported into a common data environment platform that allows the integration of sensor data installed in various pavement layers. In addition, some existing studies integrate building information models (BIM) and the Internet of Things (IoT) for road construction monitoring, which is close to the concept of DT. For example, Han et al. (2022) propose a BIM-IoT and intelligent compaction (IC)-integrated framework for road compaction quality monitoring and management.

In the operation and maintenance (O&M) phase, many road DTs are created in different ways without a specific purpose. Marai et al. (2021) present a road DT system using a 360° camera and IoT devices. The live stream, GPS location, and measurements of the temperature and humidity are dynamically sent to the DT, with interested objects (e.g., vehicles) detected and tracked. Wang et al. (2021) use 3D GIS technology to develop a highway DT, where the Computer-generated Architecture language is employed to build the road geometric model. Steyn and Broekman (2022) develop a DT prototype of a local road network that uses LIDAR, unmanned aerial vehicles, and sensor systems to capture road geometry, traffic flow data, and road environment data, respectively. In contrast, some studies discuss some potential applications of DT. For instance, Chen et al. (2022) propose a DT-based framework for road condition prediction that inputs historical and real-time data from the whole road lifecycle into machine learning algorithms to predict future road performance. Agrawal et al. (2022) invite highway experts to plan the adoption of DTs to detect pavement defects, predict future defects, and make maintenance work orders.

From the above review, it can be summarized that although there are some implementations of DT in the road maintenance phase, the application scenarios and benefits of DTs have not been systematically explored using surveys of realistic problems encountered by the highway industry. Furthermore, the existing studies primarily focus on DT generation and DT-enabled data analytics, whereas few research has investigated the requirements and challenges for DT implementations considered by the industry practitioners. Understanding the specific use of road DTs and value points could help the highway industry develop DTs as a new IM approach to solve the existing issues.

Research methodology and questionnaire design

Figure 1 shows an overview of the research design. This study first interviewed 20 highway experts from UK National Highways. The objective is to understand existing maintenance processes and the problems that underpin them. The Information Delivery Manual (IDM) (29481-1, 2010) approach is employed to represent different levels of maintenance processes along with the related actors, phases, activities, and data exchange items.

Having documented all relevant existing maintenance processes, the authors analyse the IDM documents to identify any inefficiencies in these processes. Based on the findings, together with the interview conversations and literature review, a questionnaire is designed, covering the following aspects: (a) participant role and experience; (b) barriers in current practices; (c) current use of DT; (d) perceived opportunities of DT; (e) challenges of DT implementation. Most questions are multiple-option questions, where the options come from the authors' findings (e.g., identified inefficiencies) or proposals (e.g., proposed DT applications). The questionnaire also allows participants to input their comments for most questions, in case the predefined options are not within their considerations. The questionnaire form can be accessed through the link: https://forms.gle/Nj7g7BT9D3VHo3x4A .

Finally, we disseminated the questionnaire survey through various channels, such as email invitations, LinkedIn, and Weibo. To allow relevant people to complete this questionnaire, we included prompts in the invitation that state "*the target population is individuals who work in the highway industry, especially in the following areas: (a) road survey and inspection; (b) road maintenance; (c) information system/database operation; (d) strategy making and research innovation; (e) asset management; and (f) safety management*".

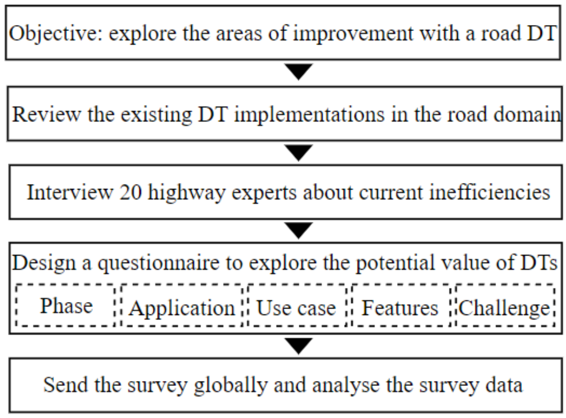

Figure 1. Overview of the research design.

Survey results and discussion

Overview

The survey data collection period covers approximately 40 days, from October to November in 2023. The number of email invitations is over 500. As a result, 183 valid responses have been obtained as valid samples for data analysis. This sample size enables a 95% confidence level with an 8% margin of error for the survey results, as calculated using Slovin's formula (Tejada and Punzalan, 2012). Given the exploratory nature of this study and the limited pool of respondents, these parameters can be deemed appropriate.

Table 1 shows the demographics of all respondents. Maintenance managers and engineers (27.9%), road inspectors (20.8), and technology developers (19.1%) occupy the largest proportions, probably because this topic gains interest from these groups. It is worth noting that some respondents selected multiple roles in this survey.

Table 1: Demographics of the 183 respondents.

Roles	Proportion
Road surveyor	14.2%
Road inspector	20.8%
Maintenance manager and engineer	27.9%
Scheme maker	10.4%
Asset manager	14.2%
Technology developer	19.1%
Network-level strategy maker	11.5%

In terms of participants' experience in the industry, 34.4% of participants have 5-10 years of working experience. People who have worked for over 10 years account for 32.8%. In comparison, practitioners who have started their careers (0-2 years) and have 2-5 years' experience make up 9% and 24%, respectively.

Main barriers in current practice

Figure 1 presents the responses from the participants regarding question 3, which is about selecting the main barriers faced by their organization in highway maintenance. It shows that "*hard to derive optimal maintenance decisions under budget constraints*" is the most selected choice (55.2%), which implies that the main limitation for the highway industry is still budget constraints. In this situation, practitioners must carefully evaluate the impacts of different decisions and prioritize the importance of different tasks, which is difficult to achieve due to several reasons. First, as the ranked second (50.8%) choice points out, much of the asset information stored in the existing maintenance management systems (MMS) and asset management systems (AMS) is inaccurate, incomplete, and unreliable, especially for old and underground assets (e.g., electricity). Second, it is still difficult to obtain comprehensive road condition data, which is also acknowledged as the third barrier. If maintenance planners do not know what happens on the entire road network, it is difficult to make informed decisions. Furthermore, 46.4% of participants agree that there is a lack of precise evaluation of the costs, benefits, and risks of alternative strategies. This is because most existing decision-support tools can only optimize short-term plans with controllable factors rather than forecasting long-term, multi-year network evolution with uncertainties incorporated.

Some respondents also identified specific problems they faced. For example, two answers illustrate that there is a lack of "*consistent operational approach*" and "*maintenance strategy based on needs*". These problems relate to other written answers that demonstrate a lack of knowledge of how asset handover works and the complexity of the data specifications of the current asset systems. The barriers occur because an increasing number of highway authorities are adopting asset information models (AIM) for managing highway assets, but maintenance people do not know how to use these asset data in their professional work. For example, the National Highways publishes an Asset Data Management Manual (ADMM) (National Highways, 2023) as their data handover specifications for all road construction projects, but they currently use another system with disparate data schemas to schedule routine maintenance.

Apart from the asset data usage problem, other written answers mention some challenges in lack of skilled workforce, lack of trust in analytical processes, communication with stakeholders, inefficient contract preparation, and difficulty obtaining road data without traffic disruption.

Current use of relevant technologies

In this survey, we also investigate the IM approaches and technologies adopted by highway organizations in the current practice. In the questionnaire, we first clarify what a DT is in the highway maintenance context: "*a digital replica of the physical highway system, encompassing road infrastructure assets, traffic elements, environmental factors, and more*." Afterward, the fourth question first surveys the participants' familiarity with the DT concept. As a result, 63.9% of participants responded

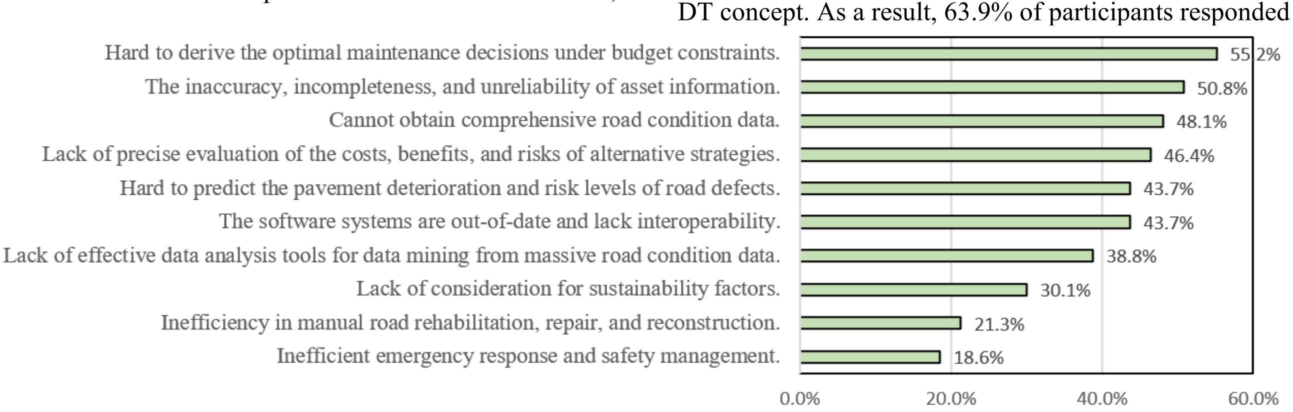

Figure 1. Responses to Question 3: "What are the main challenges and barriers faced by your organization in highway maintenance operations?"

"somewhat familiar," and 22.4% of participants chose "very familiar". In contrast, only 13.7% of participants acknowledge that they are not familiar with DTs at all.

The fifth question sought to clarify what technological approaches are currently used by participants' organizations. As shown in Figure 2, GIS is the most used technology for highway maintenance, which is intuitive because nearly all highway assets should be georeferenced in large road networks. Moreover, it was found that BIM approach is increasingly used in the road engineering domain (54.1% of participants). How to best use the road BIM files from the design and construction phases in the maintenance phase requires further studies. One potential solution is to make BIM models exchangeable with twin-based systems to realise their maximum value. In addition to the predefined options, participants also mention drone-based real-time data collection techniques and material deterioration models.

The sixth question aims to explore the contexts and projects in which highway organizations adopt DT technology and how it is used. From the answers obtained, it was found that most applications of DTs are 3D visualization to assist maintenance planners in making decisions. However, there are some noteworthy other applications, as listed in Table 2.

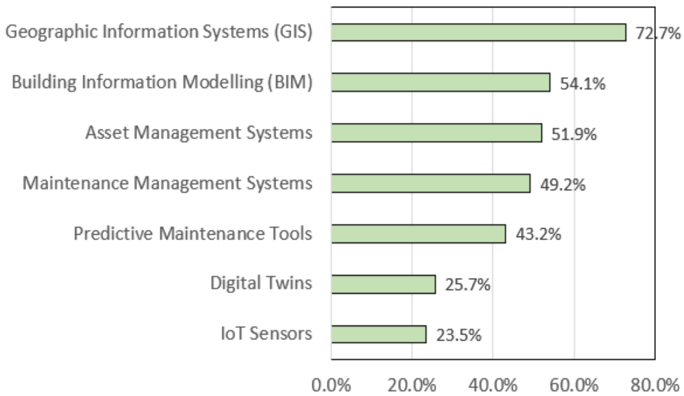

Figure 2. Responses to Question 5: "Does your organization currently use digital technologies or solutions for highway maintenance? "

Table 2: Selected answers for Question 6: "briefly describe the context or project where digital twins were/are utilized."

Current use of DT in organizations
1. Behavior/deterioration modeling of road assets.
2. Combining survey and as-built data for digital design.
3. Decision-support tools to predict maintenance needs.
4. Analysis of budget, safety, environment, flood risk, driver behavior, and fleet composition.
5. Comprehensive data storage with road asset definition, road construction, and condition data.
6. Measurement of complex road segments.
7. Real-time weather detection of the highway environment and refined weather forecast.
8. Emergency response and traffic jam management.
9. Supporting the development of autonomous vehicles.
10. Education and training.

As can be seen from the above table, some highway organizations have started to leverage the rich data in digital twins for behaviour prediction, road renovation, maintenance need estimation, and multi-factor analysis for maintenance planning. Moreover, it is worth noting that the integration of road DTs and connected autonomous vehicles (CAV) has the potential to create huge benefits for both the highway industry and the automotive industry: on one hand, the road DT can provide high-fidelity data about road conditions, providing better navigation to CAVs to avoid dangerous road defects (e.g., potholes). On the other hand, the rich data collected from CAVs driving on the network, such as images and sensing data (e.g., temperature, roughness), can be used to update the road DT in real time, which could overcome the critical problems regarding the DT data collection for the huge road network.

Potential use cases of road DT

This section of the questionnaire aims to understand how highway industry practitioners perceive the opportunities for DTs in highway maintenance. Specifically, we try to identify (a) important phases for applying DT; (b) important features that a road DT must have to take effect; (c) valuable applications of road DTs; (d) potential use cases; and (e) main benefits of road DTs.

Based on our interview, the process of highway maintenance can be generally divided into five stages:

- *Scheme making and prioritization*: experienced engineers receive annual network-level survey data and make maintenance schemes for a specific road section. All schemes must be prioritized based on severity levels.
- *Road assessment*: road inspectors physically arrive at road sites to inspect road defects. Various techniques can be used to investigate the deterioration of pavements, such as coring, deflectograph, and ground penetration radar (GPR).
- *Maintenance planning*: based on the results of inspections, maintenance planners make treatment plans with consideration of budgets, costs, labour, and risk level.
- *Maintenance execution*: based on the maintenance plans, contractors of highway authorities conduct road repair and rehabilitation using both humans and machines.
- *Quality assurance and control*: the process of quality inspection to ensure that the maintenance work reaches the required standard.

Table 3 presents the results of Question 7, showing that the stage of *Scheme making and prioritization* is the most commonly agreed phase in which a road DT can take effect. This might be because the DT can be used to check road conditions in 3D views and simulate the effects of different strategies. In addition, *Maintenance planning* is also a popular response (74.3%). By contrast, fewer participants recognize that a DT can be useful in the phases of *Maintenance execution* and *Quality assurance and control*, suggesting that the DT alone may not be useful in fieldwork that involves mainly manual work. Finally, some participants also wrote answers, such as operational planning and control, long-term investment optimization, and maintaining inventory data for soft estate assets. One answer demonstrates that the DT can enable new intelligence-led proactive maintenance that could totally change the existing processes.

Table 3: Responses to Question 7: "In which phases of highway maintenance do you see that digital twins can take effect?"

Phase	Count	Proportion
Scheme making and prioritization	148	80.9%
Road assessment	122	66.7%
Maintenance planning	136	74.3%
Maintenance execution	108	59%
Quality assurance and control	99	54.1%
None of above	2	1%

Question 8 was designed to investigate what features of road DTs are perceived as important for industry practitioners in highway maintenance. From the literature review, we summarize several key features of DTs: data transparency, data security, autonomous decision-making, prediction, simulation, data diagnostics, visualization, and data storage and integration. In the domain-specific context, we provide explanations for the following features in the questionnaire:

- Data diagnostics: identify the anomalies, risks, and their causes in the condition data.
- Simulation: simulate the operations of alternative strategies and assess their effects.
- Prediction: predict future states of roads, such as deterioration and structural failure.
- Autonomous decision-making: generate suggestions to decision-makers based on performance indicators.

Figure 3 presents the results for Question 8. As can be seen, prediction and simulation are two of the most important functional features that a road DT is expected to have. In comparison, fewer participants selected the feature of autonomous decision-making (54.6%). This implies that industry practitioners tend to make decisions on their own based on the intermediate results from DT-enabled simulation and prediction, rather than leaving them entirely with DTs. Furthermore, Figure 3 shows that the features of data transparency and data security are the least chosen (32.8% and 30.1%), suggesting that industry practitioners care more about the practical functions that a DT could bring about. In contrast, system architects and DT developers might consider these two features to be crucial.

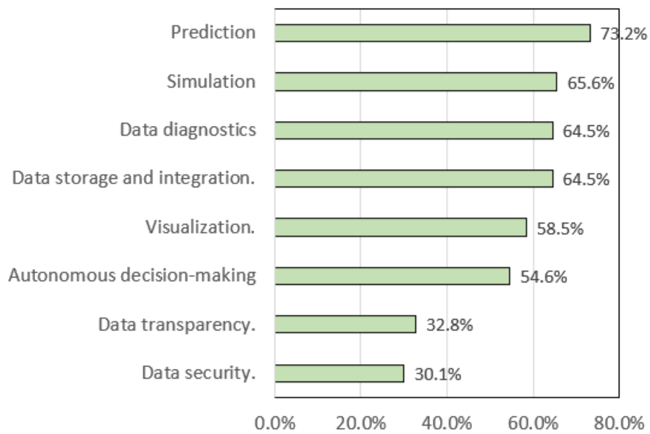

Figure 3. Responses to Question 8: "What features of a digital twin system do you perceive are important in highway maintenance?"

The subsequent question is about the application of road DTs. Based on the review and interview, the authors list several applications for road DTs, and the participants are asked to make selections of applications that they think are valuable. The result of Question 9 is presented in Figure 3. The most chosen DT application (73.2%) is *Predicting the deterioration and structure failures of road assets based on historical and dynamic road data*. In essence, deterioration prediction is a longstanding research problem in the field of highway maintenance. The role of DTs in this task is to be the data holder of historical and real-time road condition data, road construction data (e.g., material), traffic data, and climate data. The prediction of deterioration and failure depends on analytical models that process these DT data and predict the future states of pavements and other assets.

The second-ranked application is *Helping routine maintenance planners make better maintenance strategies, considering multiple factors*. From our interview, routine maintenance and reaction is one of the crucial processes to ensure the operation of the UK highway infrastructure, in which road inspectors drive on the entire network every week to visually check abnormal conditions. Maintenance planners have trouble making the best decisions in prioritizing the repair of the damaged assets and sending work orders that can minimize costs and risks. Therefore, a DT can be used to help maintenance planners make sound strategies in consideration of multiple factors. For instance, a DT may provide cost information for an asset or estimate the risks of the observed defects in association with the traffic environment. The third-ranked application is *Generating optimal plans for road investigation and repair within a* *scheme-level maintenance project.* The UK highway authorities use scheme-level road investigation and maintenance as a key strategy to systematically repair, rehabilitate, or reconstruct road sections. Within a maintenance scheme, scheme makers gather different kinds of survey data and then use their knowledge and experience to determine the treatment strategies. A road DT could aid in the creation of optimized treatment plans with less bias due to human experiences.

Question 10 is an open question that asks participants to describe at least two use cases of DTs that are valuable for highway maintenance. A total of 125 written responses were obtained. While some answers overlap with the applications listed in Question 9, many responses provide valuable insights from the viewpoints of highway experts. Table 4 presents 10 selected answers.

Table 4: Selected answers for Question 10: "Please describe the potential use cases of digital twins in highway maintenance that you believe hold significant promise."

Potential use cases of DT for highway maintenance
1. Supporting risk-based proactive maintenance and automated, human-free road inspection.
2. Live highway monitoring (traffic and pavement structure conditions) to generate instructions for emergency repair and prioritization of repair.
3. Improve predictability of maintenance need, simplicity of maintaining, and up-to-date asset record (location, condition and interventions delivered)
4. Provide data for autonomous cars/machines for snow-plowing the road; provide data for autonomous marking/paining on the road.
5. Data from inspections and maintenance activities is visualized and pinned to the asset to show it "service" history current condition and is then used to predict future maintenance interventions.
6. Understanding 3rd party productivity risks to site works e.g., PROW (Public Right of Way) or ecology; understanding 3rd party safety risks including where to park, traffic levels, works access.
7. Providing detailed incident tracking to understand real-world risks on the network and comparing with asset condition; CAV routing for maintenance and wear.
8. Highlight underground drainage defects.
9. Understanding interaction between different asset classes to help aid intelligence-led predictive modelling for best asset interventions taking account of whole life asset management.
10. Prescribing future designs and built outcomes that impact maintenance.

By analysing the collected responses, some use cases of road DTs can be realized in the short term, while others can only be achieved in a long-term period (over 10 years). For the former, the feasible use cases include integration of highway asset information with a single source of truth, visualization of inspection and maintenance activities, and decision-making for maintenance interventions. For the latter, predicting future states of roads and proactive maintenance may require the collection of road condition data and maintenance records over many years to develop usable deterioration models and approaches for risk-based predictive maintenance.

The last question (Question 11) in this section allows participants to select the potential benefits of DTs in highway maintenance. The results are presented in Figure 5. Better asset lifecycle management, cost savings, enhanced operational efficiency, and improved decision-making are recognized as the main benefits that digital twins can bring to the field of highway maintenance. It suggests that a road digital twin should incorporate asset management principles to facilitate better operational and maintenance planning. Hence, a DT not only serves as a data hub to store and integrate road data but also provides processes and workflows for lifecycle management, from data collection and data updating to the usage of asset data.

Perceived challenges of DT implementation

In the previous section of the questionnaire, the potential use cases and benefits of road DT are studied. However, it is also important to be aware of the challenges of adopting DT approach for highway organizations to better understand which use cases can be implemented in the short term and which use cases require long-term investment and development, thus deriving a reasonable technical roadmap for DT standardization, development, and promotion. Therefore, the last section of the questionnaire investigates the difficulties perceived by

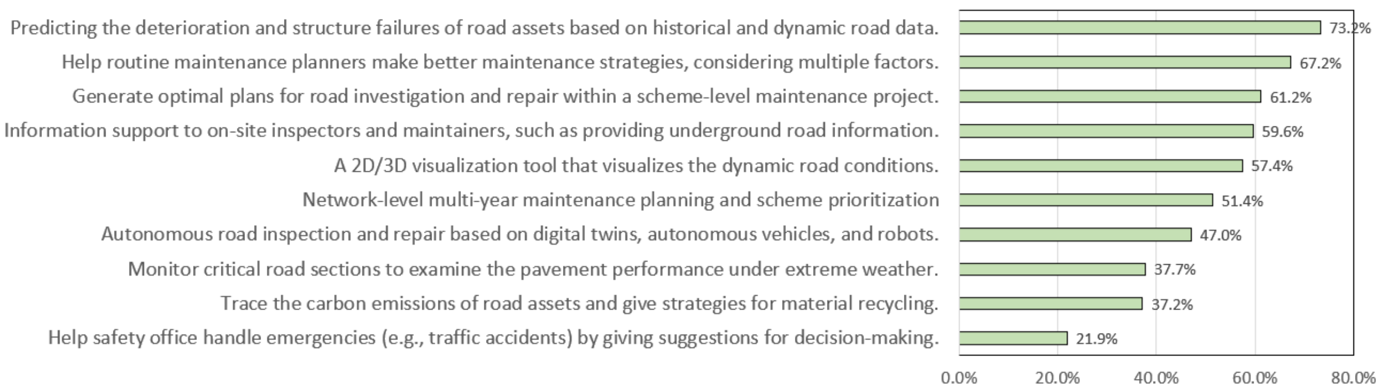

Figure 4. Responses for the Question 9: "Which of the below digital twin-based applications do you perceive are important and valuable in highway maintenance?"

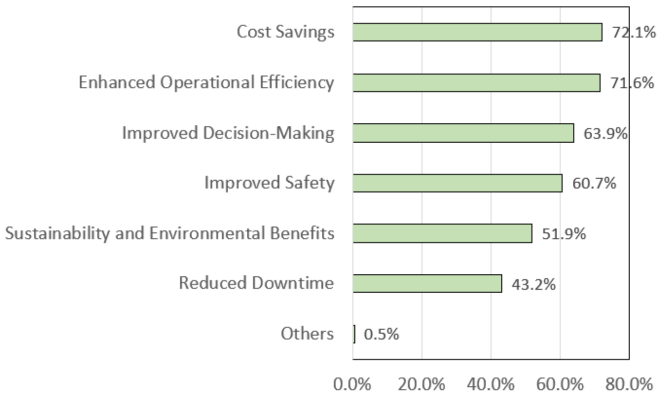

Figure 5. Responses for the Question 11: "Please select the potential benefits you expect digital twins to bring to highway maintenance."

industry practitioners when it comes to implementing DTs for their organizations.

As presented in Figure 6, the responses for Question 12 show that the top 3 challenges of DT implementation are (a) skills and training gaps (61.2% selected); (b) lack of data integration (55.7% selected); and (c) lack of standardization (51.9% selected). It suggests that training and education for highway practitioners to use new DT technologies and systems will be a significant issue because they become accustomed to the existing tools (e.g., GIS). Hence, the design of user-friendly human-DT interfaces is important to reduce the negative impacts of training costs and user reluctance towards new technologies.

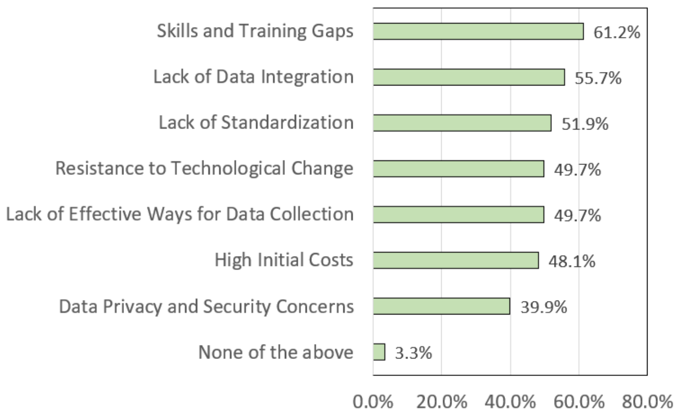

Figure 6. Responses to Question 12: "Please select the primary challenges or barriers you foresee in implementing digital twins for highway maintenance."

The challenge of data integration stems from several aspects. First, the connection of the new DT system with the existing systems and databases used by highway organizations is difficult, requiring a heavy workload of manual alignment between different data schemas. Second, when the road DT has new data requirements about road construction and condition, it is challenging to update the old asset data according to the new requirements, which would induce much missing or mismatched information. Third, designing a data schema for road DT that has sufficient interoperability and scalability is itself an intricate task. This also relates to the 3rd-ranked challenge: lack of standardization. A well-defined data standard is crucial for DT instance creation and information exchange between different DTs.

Apart from the options shown in Figure 6, some respondents also input other problems for implementing DTs in the highway industry, as shown in Table 5.

Table 5: Selected written answers about the challenges of DT implementation.

Other challenges of road DT implementation
1. Lack of political understanding of the urgency.
2. Silo mentality: different sectors or organizations involved in highway maintenance operate independently and without much coordination or information sharing.
3. Technical integration of emerging technologies.
4. Leadership challenge.
5. The cost of maintaining DTs may exceed the values they create.
6. Lack of trust in the analytical processes
7. The DT data obtained from existing databases may have poor levels of accuracy.
8. Procurement of the DT systems and meshing with the existing maintenance systems.

From the above table, policy support, coordination between organizations, and cost estimation for maintaining DTs are also issues for implementing DTs in the highway industry.

Conclusions

Maintaining highway assets at the required service level is critical to ensuring the efficiency and safety of road networks. The digital twin (DT) concept has the potential to be applied in highway maintenance and improves existing processes based on dynamically updating digital road models. This paper presented a questionnaire survey for highway industry practitioners to identify the main barriers in current practice and potential use cases of DTs in this field. The questionnaire was designed based on previous interviews with highway experts in the UK industry, and it was then disseminated globally, with 183 responses obtained from professionals across different roles in the highway industry.

The findings reveal a consensus on the main inefficiencies in highway maintenance: the complexity of making optimal maintenance decisions under constraints, the poor quality of asset inventory information, and the difficulty of acquiring comprehensive road condition data. The survey also indicates that the DT can be potentially used for deterioration prediction, maintenance planning, and scheme development, taking advantage of its well-structured, dynamically updated road asset information in cyberspace.

This study contributes to the knowledge of how industry practitioners perceive the prospects and challenges of road DT in highway maintenance, which provides valuable insights for the design and implementation of road DTs. The results of this survey can be effectively used by academia and industry to develop a purpose-driven approach for applying DTs in the highway maintenance field, where the most valuable use cases with fewer technical and managerial challenges could be implemented first and DTs can be progressively improved to realise more application values. In future work, the survey data will be further analysed based on the roles and experiences of participants.

Acknowledgments

This project has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 101034337. We wish to thank Dr. Pieter Pauwels, Dr. Stefano Cavazzi, Yogesh Patel, Matt Peck, Katrin Johannesdottir, and Simon Hayton for their contributions to this paper.

RENOVATION DIGITAL TWIN FOR BUILDING RETROFIT MONITORING: A SOFTWARE PRODUCT AND AN ORGANIZATIONAL ECOSYSTEM

Omar Doukari* and Ala Suliman
Faculty of Engineering and Environment, Northumbria University, NE1 8ST, UK

Abstract

To meet the European energy-saving and decarbonisation goals, the delivery of renovation projects must be accelerated. Automated processes and software tools are crucial to facilitate and optimise the project execution and onsite monitoring by providing early warnings and notifications to the project team. Digital twins are one of the most promising approaches as they provide real-time data and use simulation to inform and speed up decision-making processes. This paper presents the design, development, and deployment of a Renovation Digital Twin (RDT) that enables monitoring of the retrofitting progress and the provision of feedback to the project stakeholders. The RDT aims at addressing a set of seven design requirements including compliance with the General Data Protection Regulation (GDPR) while sensing building data. The RDT integrates 13 Key Performance Indicators (KPIs) allocated to five application domains: quality, cost, scheduling, safety, and environment.

Introduction

To achieve the energy-saving and decarbonisation goals of the European Union, the delivery of renovation projects must be accelerated. The adoption of digital twining technologies in construction and renovation project is one of the most promising approaches. Digital twins (DTs) refer to the creation of exact digital replicas or virtual representation of an object or system that spans its lifecycle. Each replica possesses the properties and/or behaviours of a system in the physical world. These digital replicas are updated from real-time data, and use simulation to optimise decision-making processes (Tuhaise *et al.*, 2023).

DTs offer several advantages in the construction industry. They enable improved resource management by optimising energy usage, reducing the carbon footprint of buildings, and providing real-time access to as-built models, thus fostering harmonisation between current progress and future deliverables. Moreover, DTs enhance collaboration by enabling all stakeholders to access a shared digital representation of a project, improving communication and collaboration between engineers, architects, contractors, and other team members. Furthermore, they help minimise waste, reduce construction costs, and identify and mitigate potential safety hazards on construction sites, ultimately improving the efficiency, quality, and safety of construction projects while reducing costs (Tao *et al.*, 2018). Hence, in construction industry, DTs can be leveraged to reduce costs, accelerate delivery, enhance the safety, and provide efficient monitoring of projects throughout their lifecycle (Saback de Freitas Bello *et al.*, 2023).

Monitoring activities is a critical task in construction project management. DTs can be utilized to monitor onsite construction activities to offer real-time insights and predictive capabilities. By integrating various data sources such as 3D models, IoT (Internet of Things) sensor data, and building information, DTs enable the continuous monitoring of construction processes, allowing for the early detection of potential issues and the optimization of resource utilization. This proactive approach enhances safety, risk management, and contributes to improved efficiency and quality of construction project (Greif *et al.*, 2020). As a result, the adoption of DTs for onsite monitoring has a great potential to be a valuable tool for construction project management and execution.

Decarbonization and energy-saving are global and urgent goals of the construction industry. Onsite monitoring of renovation activities is crucial to approach these goals as it supports accelerated project delivery. Although DTs is a promising technology in approaching these goals, only a few research has been conducted so far, to effectively demonstrate the design, development, and usage of such technologies. The situation is more challenging in building retrofit where existing tools are usually lacking or adapted from new build construction tools. Hence, this paper aims to present the design, development, and deployment of a Renovation Digital Twin (RDT) that enables monitoring of the retrofitting progress and the provision of feedback to the project stakeholders.

The remainder of the paper is structured as follows. Section 2 summarises research works and gaps related to the topic being addressed by the research. Section 3 presents the research methodology implemented to achieve the research objectives, and introduces the solution proposed which includes the digital twin developed for renovation projects monitoring, integrating a set of KPIs identified with the help of the RINNO project's industrial partners. Conclusions, limitations and future works are finally outlined in Section 4.

Previous Works

The concept of DTs in the context of building renovation and onsite retrofitting works has garnered increasing attention within the architecture, engineering, construction, and operations (AECO) industry. Pan, et al. (Pan *et al.*, 2023) discuss the emerging and anticipated benefits of DTs in the building deep renovation life cycle, emphasizing their potential to reshape the process of assets' construction and maintenance through decision encoding. The authors highlight that while the applications of DTs are still at an early stage, they hold promise for various stakeholders involved in AECO, provided that their full potential is effectively exploited (Pan *et al.*, 2023).

In a similar vein, a systematic review by Opoku et al. (Opoku *et al.*, 2021) delves into the status, evolution, and key applications of digital twins in the construction industry. The review provides insights into six areas of application in the lifecycle phases of a construction project, shedding light on the diverse contexts in which DTs can be leveraged within the construction domain. These application areas include building information modelling, structural system integrity, facilities management, monitoring, logistics processes, and energy simulation (Opoku *et al.*, 2021). Similarly, Tuhaise et al. (Tuhaise *et al.*, 2023) identified key technologies, research gaps, and future research directions, focusing on technologies in data transmission, interoperability, data integration, data processing, and visualization. From a different perspective, Ammar et al. (Ammar *et al.*, 2022) conducted a study that explored the applications and challenges in construction through interviews. Their analysis identified 40 applications and uncovered 34 implementation challenges. The study also presents a case study that exemplifies the practical implementation of DTs in a construction setting, underscoring the potential for different information pipelines from the site to decision-making processes (Ammar *et al.*, 2022).

Research Gaps and Contribution

Managing a renovation project presents several challenges for project stakeholders and policymakers, such as disruption to, and by occupants, which usually lead to more time and cost overruns, more health and safety hazards, and worse quality performance when compared to new-built construction projects (Doukari, Wakefield, *et al.*, 2024). The literature review conducted collectively underscores the transformative potential of DTs in synchronising and enhancing the performance of construction activities and ensuring better control of the cost, time, safety, and quality of construction projects. Despite that, the use of DTs in building renovation and onsite retrofitting works was noticed to be limited in this literature body, and no comprehensive framework has been yet proposed. Hence, implementing this technology in building renovation should offer valuable insights into their evolving role and improve the efficiency of monitoring onsite retrofitting activities.

The contribution of this paper is twofold: (i) present a novel RDT solution (i.e., product system) that enables monitoring of the retrofitting progress and the provision of feedback to the project stakeholders; and (ii) provide detailed descriptions of the Research and Development (R&D) methodology implemented (i.e., organizational system) which includes the design, development, and deployment processes as well as the technological ecosystem required for the software product development.

Renovation Digital Twin – RDT

The RDT platform is developed to enable monitoring of the retrofitting progress and the provision of feedback to

Table 1: Renovation Project KPIs

Application	Description	Calculation	Representation
Quality	1- Number of quality incidents 2- Monitoring the quality controls 3- Number of customer complaints 4- Identification and alerts on recurring quality issues	1- Number of opened quality incident forms 2- Quality controls to be done in the next 10 days 3- Number of customer complaints 4- The 5 most recurrent quality issues	1- Line chart 2- List 3- Line chart 4- List
Cost	5- Cost savings 6- Cost overruns	5- Sum of the registered savings 6- Sum of the registered overrun costs	5- Line chart 6- Line chart
Scheduling	7- Delay monitoring 8- Milestones monitoring 9- Duration for resolving issues	7- Difference between days worked and days scheduled 8- % of achieved, ongoing and upcoming tasks 9- Average duration between opening and closing issues	7- Line chart 8- Pie chart 9- Line chart
Safety	10- Identification and alerts on recurring safety issues 11- Number of safety incidents 12- Monitoring safety incidents control	10- The 5 most recurrent safety issues 11- Number of safety issues 12- Stakeholders involved in safety issues	10- List 11- Line chart 12- List
Environment	13- Monitoring waste	13- Number of recorded waste containers	13- Line chart

the project stakeholders. Its main role is to: (i) gather onsite information about weekly project safety, quality, cost, completion of tasks and delays, and information related to waste management; and (ii) provide the project stakeholders with timely insights to take appropriate actions if needed.

Methodology

The research and development methodology implemented to achieve the research objectives is based on a 5-step process (Figure 1):

- First, workshops with onsite construction workers, project and site managers and engineers are organised in order to identify the most relevant information they need to be regularly reported during the retrofitting phase of a renovation project. For two days, fourteen participants from the RINNO project's industrial partners contributed to the identification of renovation project stakeholders' needs and system requirements in terms of onsite information and progress notification;
- Second, this input was categorised into different application domains, including quality, cost, scheduling, safety, and environment to facilitate KPIs identification;
- Third, for each application domain, a list of KPIs for retrofitting works monitoring is defined, and their sources of data, calculation formulas, representation formats, and frequency of measurement are detailed (Table 1);

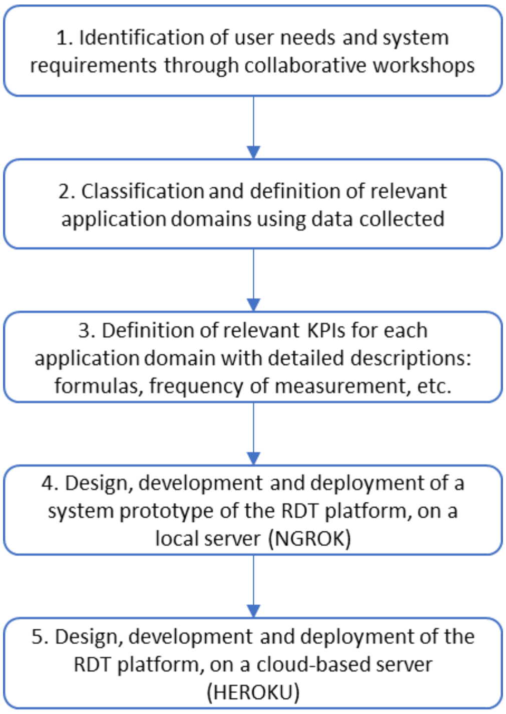

Figure 1: Research and development methods.

- Fourth, a system prototype, including main functionalities and user interfaces, is developed so as to enable both testing and validation with site managers and workers. This first version is deployed on a local machine, and remote access for testing purposes, is enabled using NGROK (NGROK, 2024);
- Fifth, a final version of the RDT platform is developed enabling the integration of the BIM model of the building being renovated along with a set of friendly graphical user interfaces (GUIs) for project KPIs visualisation and user notifications. This final version is deployed on HEROKU (HEROKU, 2024).

Design Requirements

The starting point of the RDT platform development is the set of design requirements (DR), including components and high-level functionalities, that have been identified with the RINNO project's industrial partners (Point 1, Figure 1). As presented in Table 2, seven requirements must be met to develop a suitable digital twin platform for renovation projects.

Table 2: Design requirements of the RDT platform.

DR1: Regularly provide relevant project KPIs regarding quality, cost, scheduling, safety, and environment (Table 1).
DR2: Store historical project KPIs during the retrofitting phase.
DR3: Simulate project KPIs and their progress overtime.
DR4: Provide a user-friendly interface through integrating BIM and relevant charts and/or graphs.
DR5: Enable stakeholders' notification when project KPIs exceed specific thresholds.
DR6: The RDT platform should be accessible anywhere and at any time for all project stakeholders through internet.
DR7: Comply with regulations, such as General Data Protection Regulation (GDPR), while sensing building data.

System Architecture

The RDT platform architecture presented in Figure 2 shows seven main components that help meet and implement the seven design requirements identified in Table 2. The RDT components and their relationships to the design requirements can be summarised as follows:

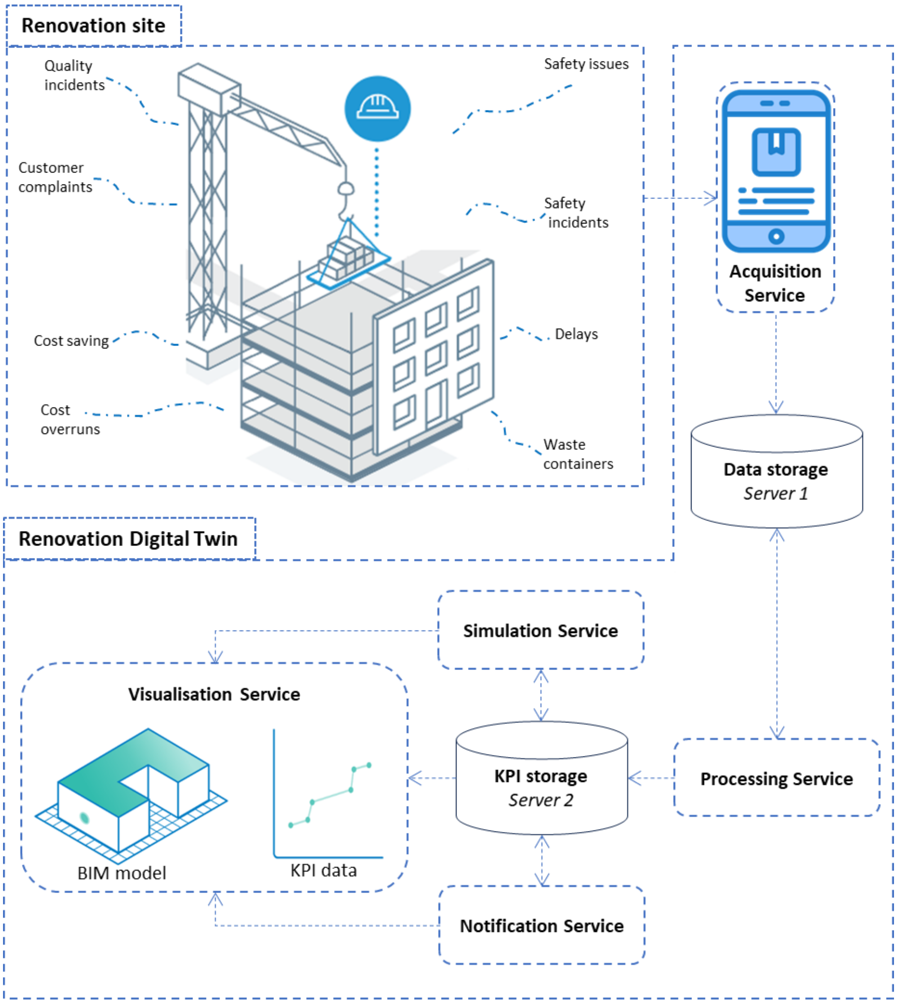

Figure 2: Renovation Digital Twin – RDT System Architecture.

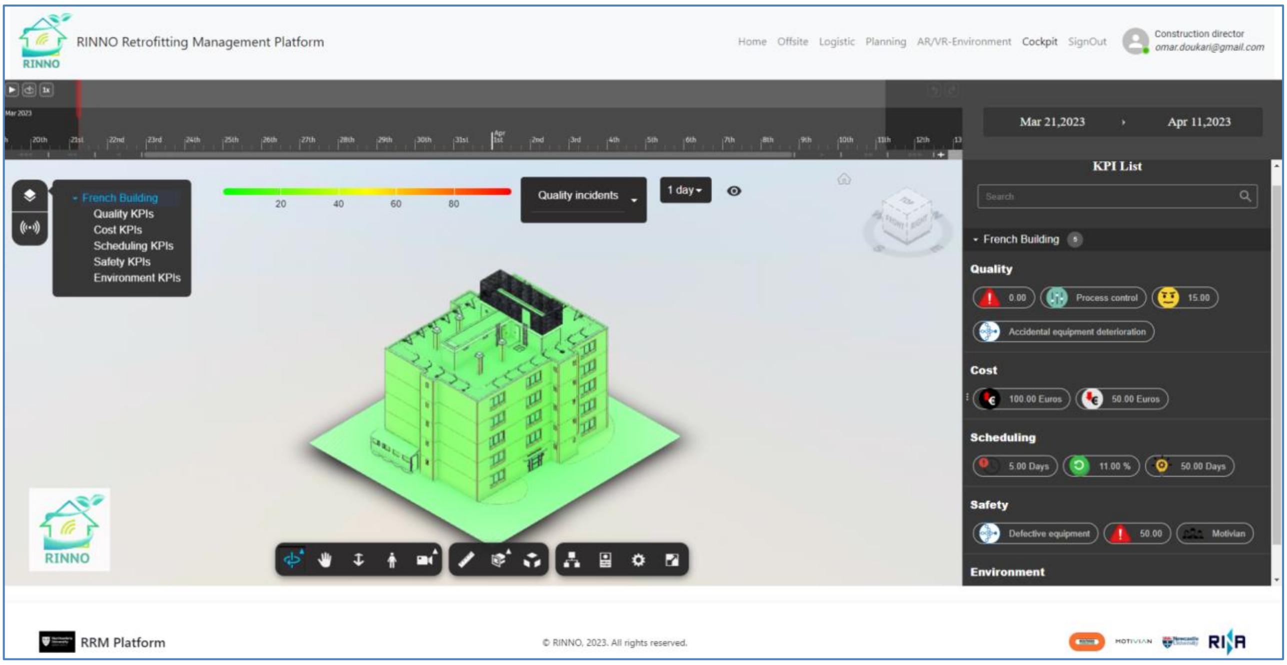

Figure 3: Renovation Digital Twin – RDT main UI.

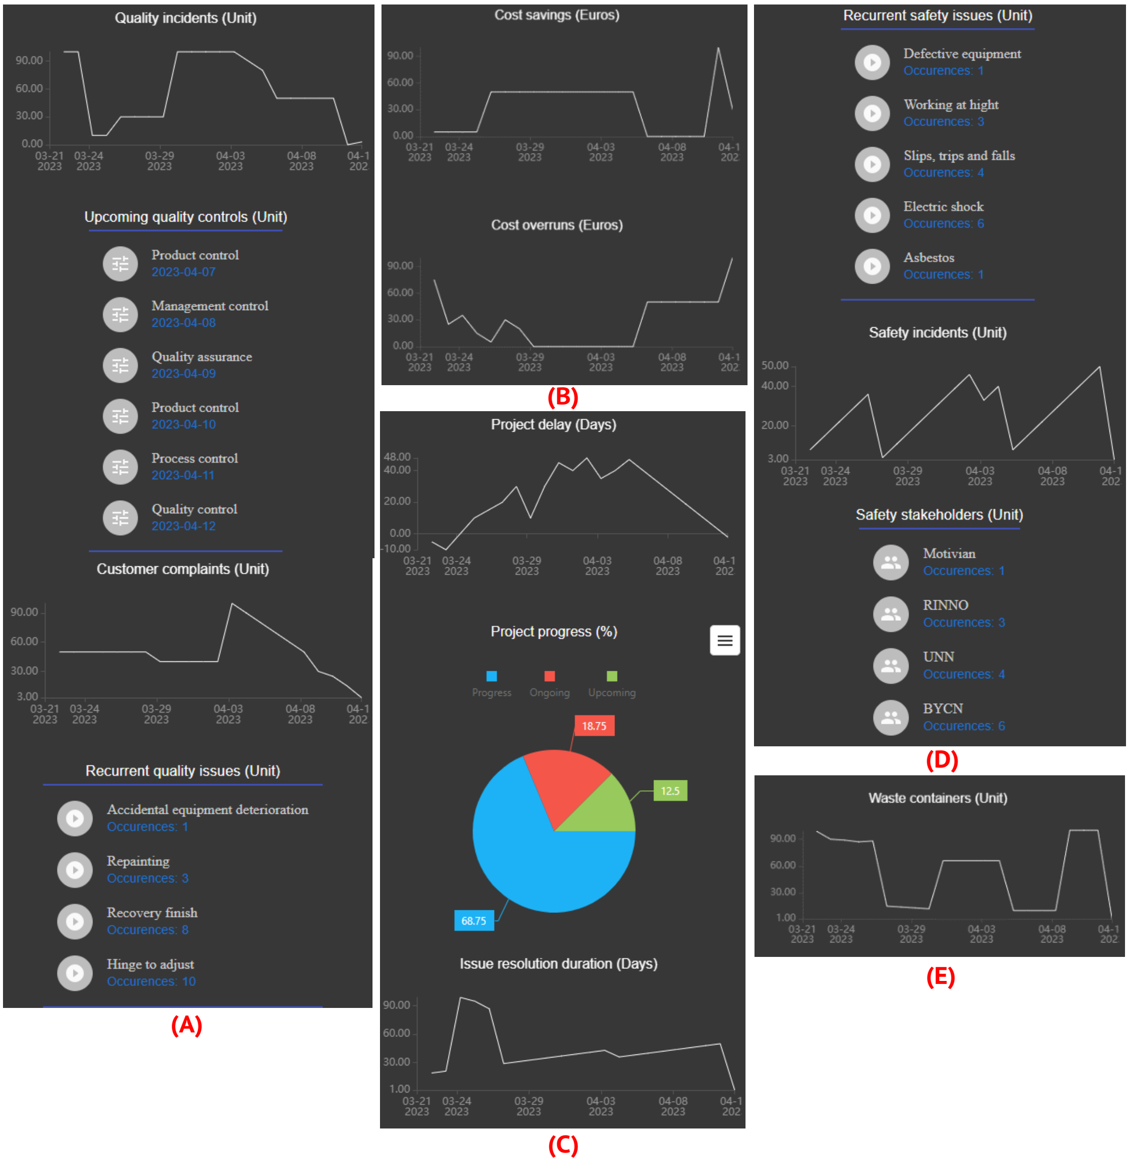

Figure 4: The RDT platform KPIs' dashboard for (A) Quality (B) Cost (C) Scheduling (D) Safety (E) Environment.

- **Acquisition service**: enables collecting raw data (ex. quality incidents, complaints, safety issues, etc.) from the onsite execution of the renovation project, and sending them back to be stored into the Data storage server. To comply with the GDPR regulation as stipulated by **DR7**, the Acquisition service is implemented as a mobile application instead of installing smart sensing devices such as sensors, which may need occupants and operators consent to data access (Doukari, Seck, Greenwood, *et al.*, 2022). The mobile application is used by the project manager to collect daily data related to the project progress and execution.

- **Data storage**: consists of a Structured Query Language (SQL) Server that stores daily project data collected through the Acquisition service. It also provides raw data for the 'Processing service' so that project KPIs can be calculated and stored as required by **DR1**.

- **Processing service**: enables calculating project KPIs using project's raw data stored into the Data storage component. It uses simple SQL queries to fetch data from Server 1, calculates the project KPIs, and then stores them into the KPI storage component (Server 2). As such, the Processing service helps meet requirement **DR1**.

- **Notification service**: consists of a 'background process' that runs continuously as a 'KPI Watcher' and triggers notifications when KPI threshold values are reached or exceeded. For each KPI in Table 1, min and max values are defined. While the min values are set to check data quality and consistency, the max values help trigger notifications via color-coded information displayed through the Visualisation service. The Notification service addresses requirement **DR5**.

- **Simulation service**: consists of simulating historical KPI values which are stored in Server 2 and their progress overtime. The result is visualised through a 'Timeliner' implemented and integrated into the Visualisation service. The KPI values are also simulated as shading and color-coded data into the BIM model elements using Forge APIs (Application Programming Interfaces). As such, the Simulation component enables '4D BIM simulation' (Doukari, Seck and Greenwood, 2022) aiming to meet requirement **DR3**.

- **KPI storage**: consists of a second SQL Server that stores project KPIs calculated by the Processing service. It feeds all RDT services (i.e., Simulation, Notification, and Visualisation) with KPI values through responding to SQL queries. This component implements **DR2**.

- **Visualisation service**: implements the main component where all visualisation, simulation and notification are displayed. The service integrates the BIM model of the building being renovated through Forge APIs, so as to allow end-users to access and easily visualise data related to current and/or historical project KPIs regarding quality, cost, scheduling, safety and some environmental aspects such as waste. This includes visualisations as shading created on top of the BIM model, 4D BIM simulations using the Timeliner, and through charts and graphics as illustrated in Figures 3 and 4. The Visualisation service answers requirement **DR4**.

Finally, to comply with requirement **DR6** and enable project stakeholders to access data anywhere and at any time, the RDT platform's architecture is designed and developed as a web-based application.

Development & Deployment

The RDT is developed using JavaScript for the backend, and React library (React, 2022), CSS and HTML technologies for the frontend (Figures 3 and 4). Particularly, MUI library (MUI, 2022) is used in order to ensure simplicity, clarity and responsiveness of the user interface (UI) components implemented, and so enable visualisation in different contexts (onsite and offsite) and on several device types with different hardware and software specifications, including smartphones, tablets and laptops. The RDT integrates Forge APIs and its main

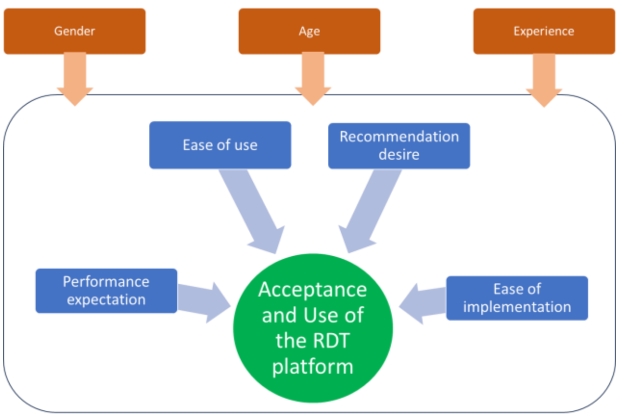

Figure 5: UTAUT model adapted to test and evaluate the acceptance of the RDT platform.

UI was inspired by a previous prototype version developed and shared by Autodesk (Sample Application, 2023).

As for the RDT deployment, it is processed following a 2-step process. First, for testing purposes, the platform is deployed on a local machine through NGROK (NGROK, 2024) and made accessible to the RINNO project's industrial partners so as to demonstrate its design and validate its functionalities. Second, the RDT is finally deployed on a permanent basis through HEROKU which is a cloud-based platform providing publication services for third-party web-based applications (HEROKU, 2024). A short demonstration video of the RDT platform in action can be visualised at (Doukari, 2024). The developed platform integrating the BIM model of the French demonstration site, which is one of the RINNO project's case studies (Doukari *et al.*, 2021), can be accessible online at (Doukari, 2023).

Conclusion, Limitations, and Perspectives

Despite the clear and obvious added values that DTs can provide to the construction industry, only little research have been conducted to showcase practical development and use of such technologies. The situation is more complex in renovation projects because of the dearth of digital tools and automated processes which are often adapted from new build construction tools, while such technologies are much more needed in building retrofit in order to expedite the delivery of renovation projects and meet the European energy-saving and decarbonisation goals by 2050 as per the EU commitment. In addition, specific requirements, such as complying with the GDPR regulation, may need to be addressed while conducting retrofitting works. To overcome these challenges, this paper introduced a Renovation Digital Twin (RDT) platform to enable monitoring of the retrofitting works and so accelerate the rate and amount of renovation projects in Europe. The adopted approach included the design, development and deployment of the RDT so as to document the process implemented and so enable reproducibility of the results. However, the research presents some limitations which can be summarised as follows: (i) the BIM model integration through the 'Visualisation service' is based on a semi-automatic process where the digital mock-up of the building under renovation first needs to be created and uploaded in the cloud, and then related (hosting) data must be updated within the RDT. To enable an efficient lean-based renovation project management as described in (Doukari, Kassem, *et al.*, 2024), a smooth and automatic BIM data preparation needs to be adopted; (ii) the 'Simulation service' enables 4D BIM simulation but only to visualise historical KPI values. There should certainly be much more benefits for the project participants if the simulation capabilities could be extended to predict future KPI trends using machine learning techniques (Rogage and Doukari, 2024) and/or a scenario-driven approach (Doukari, Wakefield, *et al.*, 2024); and finally (iii) future extensions of the research should investigate the acceptance and use of the RDT by end-users through its application and implementation within a real-world renovation project. An adapted version of the UTAUT model (Unified Theory of Acceptance and Use of Technology) (Dwivedi *et al.*, 2019) will be used to evaluate the RDT's performance and overall suitability for the management and delivery acceleration of renovation projects (Figure 5).

Acknowledgments

The authors would like to gratefully acknowledge the useful assistance, help and support received from Boubacar SECK and his MSc. BIM students at CESI Engineering School in Paris (France) during the deployment of the RDT platform (CESI, 2024). This work is supported by the European Union's Horizon 2020 Research and Innovation Programme through the RINNO project (https://RINNO-h2020.eu/) under Grant Agreement Number 892071.

THE INNOVATIVE POTENTIAL OF GENERATIVE PRE-TRAINED TRANSFORMERS (GPTs) FOR QUALITY INSPECTIONS IN SWEDISH CONSTRUCTION PROJECTS

Dimosthenis Kifokeris[1], Jan Kohvakka[2], Christian Koch[3,4], and Donia Aslanzadeh[5]
[1]Chalmers University of Technology, Gothenburg, Sweden; [2]Incoord, Stockholm, Sweden; [3]Halmstad University, Halmstad, Sweden; [4]University of Southern Denmark; [5]Robert Dicksons Stiftelse, Gothenburg, Sweden

Abstract

Approaching quality inspection plans in Swedish construction projects as mere checklists and minimizing the clients' involvement, can reduce their value. We propose improving this process through a general cloud service concept for clients, designers, and contractors, utilizing generative pre-trained transformers (GPTs). Methodologically, we synthesize literature insights on GPT uses for construction, and empirical inquiries on developing a quality self-inspection service. We posit that through such a service, project knowledge, known quality defects and lessons-learned from previous cases can be better accessed and shared – potentially leading to time savings, suggesting best practices, and improving the collaboration among clients, designers, and contractors.

Introduction and background

In the Swedish construction sector, quality errors and defects have been annually costing ca. 100 billion SEK (ca. 8.8 billion €) (Boverket, 2018). According to Koch et al. (2020), quality problems derive from a broad set of causes, incl. design failures (e.g., detail mistakes, incomplete documents, and faulty technical aspects) execution errors on site, weather disturbances, and more. Koch and Jonsson (2015) showed that the presence of such quality defects forms a recurrent reality in Swedish construction sites.

The existence and reproduction of quality defects must be understood in context. In Sweden, the responsibility of complying with the relevant regulatory framework is handed over to the contractors and designers through a series of self-inspections and reporting of inspection and testing, labelled as "self-control" (Tolstoy, 2012; Koch and Jonsson, 2015) – statutory in the Swedish Planning and Building Law (PBL 2010:900). Critically, the industry's established practice in connection to quality self-inspections reflects "a sufficiently high quality" logic that has been reported to reduce the process into more of a "check listing" rather than an actual business strategy (Koch and Jonsson, 2015). In some cases, site managers and/or craftsmen take the implementation of quality self-inspection upon themselves (Koch and Jonsson, 2015). This is a practice which, while potentially benefitting from professional experience (Koch and Jonsson, 2015), can indeed be adversely affected by complex and ingrained behaviors and a lack of communication and commitment between both the professionals enacting the self-inspections. The collaboration with the clients can also suffer (Engström and Stehn, 2016) – with the latter often experiencing a reduced understanding of and commitment in the process and its results. Underpinning this problem, Koch and Buser (2020) have also identified that the formal quality control system in Sweden (incl. self-inspections) is unable to bridge the gap of quality understanding between the project and company headquarter levels.

Given the above, and as social practices in construction (incl. reactive and proactive problem solving) can exacerbate the reproduction of quality defects (Koch and Schultz, 2019), it can be derived that the way self-inspections are understood, implemented, and shared by the relevant actors, is connected with the recurrence of quality defects in Swedish projects.

Therefore, in this paper we address the research question of how we can improve quality self-inspection in Swedish construction, by proposing the concept of a general cloud quality self-inspection service for clients, designers, and contractors, based on generative pre-trained transformer (GPT) AI. The core proposition is that professionals performing quality controls can be provided with a much larger knowledge basis for planning and executing inspections through GPT systems. GPT systems, while popularized through ChatGPT, are little understood in the construction context, with only few studies mapping relevant opportunities and challenges (e.g., Ghimire et al. (2024)), sparse early stage attempts of leveraging such systems for construction applications (e.g., Zhen and Fischer, 2023), and virtually no efforts explicitly focused on construction quality.

Following this Introduction, the paper's research method is described. Then, a literature review on the limited GPT state-of-art for construction is conducted. Afterwards, our relevant empirical insights, as derived from four consecutive research projects (three concluded and one ongoing) on the development of a Swedish cloud-based service for quality self-inspection, are summarily offered. The insights from the literature review and our empirical studies are then synthesized into our proposed concept. Finally, we conclude with some discussion points, end remarks, and recommendations for future research.

Research method

This paper builds on the aforementioned background, a literature review, and empirical work, to develop a concept attempting to address the stated research question.

The literature review of this study concerns a summary of standing quality-related considerations within the

Swedish construction sector and its self-inspection processes (forming the background for the introductory section), as well as the (very limited) state-of-art-research on using GPT-based tools for construction. It is based on a concept-centric literature review enhanced by units of analysis that was conducted in iterations (Webster and Watson, 2002). The main searched concepts were "construction quality in Sweden", "quality inspection in Sweden", and "application of GPT in construction". The emerging units of analysis included, indicatively, "GPT use for construction quality". Finally, exclusion and inclusion criteria (e.g., contextual relevance) were applied on the found sources (Dundar and Fleeman, 2017) for finally resulting in the ones featured in the current study.

Our empirical material draws from three development projects in Sweden (concluded, respectively, in 2018, 2019, and 2022), as well as an ongoing one (2023-2024), where we have been working on developing a digital tool as a cloud service (software-as-a-service) for quality assurance and self-inspection in construction. This cloud service is intended as a tool for clients, designers and contractors who actively want to work with quality assurance and self-inspection – as it has been shown that this active and systematic work is expected to contribute to better project quality and a reduction in errors and defects. Our empirical insights were obtained in those projects through various qualitative methods (Bell et al., 2019), including, among others, expert interviews, focus group meetings, market observations, conceptualizations of recommender systems based on different (not GPT) algorithms, and an incorporation of methods of analyzing construction quality defects and their sources, like the "stumbling stone" analysis in Apelgren et al. (2005).

Finally, we synthesize the research units of our literature and empirical results (Bell et al., 2019) into our proposed concept of a cloud quality self-inspection service for clients, designers, and contractors, based on GPT-powered AI, and discuss its potential strengths and weaknesses, as well as opportunities and challenges in its implementation.

Literature review

In order to substantiate this paper's background, accompany its empirical material, and inform the conceptual design of the cloud GPT-based platform, this literature review will go through the state-of-art uses of GPT within construction in general, and with regard to quality control in particular.

In short, generative pre-trained transformers (GPT), as a framework of generative AI, are a type of large language model (LLM) – i.e. artificial neural networks used in natural language processing (NLP) tasks (Abdullah et al., 2022). GPTs are based on the transformer architecture – namely, they are pre-trained on very large datasets of unlabeled text in order to generate human-like responses to queries (Abdullah et al., 2022). According to Saka et al. (2023), while in the 2020s other LLMs like BERT have been experimentally applied in construction for a few cases outside of quality management, GPT models are still relatively new in the field. This is indicated in the few retrieved relevant publications describing dedicated systems – with none of them explicitly addressing quality management and control (Abioye et al., 2021; Amer et al., 2021; Prieto et al., 2023; Uddin et al., 2023; You et al., 2023; Zheng and Fischer 2023; Saka et al., 2024). Moreover, the use of GPT in those studies also exhibits particular limitations per case.

In particular, Amer et al. (2021) used the light version of GPT-2 to integrate master schedules with look-ahead plans, with the main limitation being the intense need for manual data pre-processing. Abioye et al. (2021) discussed how GPT models can assist the project team in performing impact analyses on how change orders can affect the project scope, and identified the appropriate representation of fragmented language as a major limitation. Prieto et al. (2023) used ChatGPT-3.5 for supporting the scheduling of construction tasks, while Uddin et al. (2023) implemented it to facilitate site hazard recognition and support construction safety education. However, none of the latter two studies featured a quantitative evaluation of their results, and the systems exhibited inadequacies with zero-shot learning (i.e., the ability of the learner to correctly predict the class of new observed samples, without the latter belonging to a class observed through training (Xian et al. (2020)). Zheng and Fischer (2023) introduced a prompt-based visual assistant integrating ChatGPT-3.5-turbo with BIM for better information retrieval, but the system was limited to single-turn conversations and no quantitative evaluation of the study's results were offered. You et al. (2023) used ChatGPT-4 for automated construction task sequence planning in robot-based assembly, which was however limited to not being able to utilize visual information. Aladağ (2023) assessed the performance of ChatGPT in construction risk management as moderate, with it providing more accurate knowledge in risk response monitoring, and less so in risk identification and analysis. In a later study, Zhang et al. (2024) used ChatGPT-4 for automated data mining connected to building energy management, which showed the potential of the system in energy management, but also identified its limitation connected, mainly, to its demarcated domain knowledge and almost exclusive reliance on the users' own skills to understand and evaluate its prompt results. Finally, Saka et al. (2024) developed a GPT-based material selection and optimization prototype that integrated BIM data through the OpenAI API, with the limitations of it requiring the identification of the specific component to provide accurate responses.

Underpinning the potential exhibited in systems such as the above, Ghimire et al. (2024) identified relevant opportunities for using GPT in construction, as in, indicatively, document and data management, AI-generated designs, task forecasting, project data synthesis, and material assessment. However, they also identified challenges connected to, among others, the GPT learners' limited domain knowledge, the over-reliance on the users' analytical skills to interpret GPT-generated results with regard to their accuracy, generalizability, and interpretability, a high cost of integration, non-updated regulations on implementation, and potentially unethical data use (Ghimire et al. 2024).

Notably, full publications on utilizing GPT systems for construction quality issues could not be found during this review, with only some initial ideas identified in pre-prints like the one by Rane et al. (2023) – where the authors investigate GPT along with augmented reality (AR), virtual reality (VR), and BIM, for identifying defects and deviations from standards in quality control. Also, at this early-stage study, the aforementioned opportunities and challenges identified by Ghimire et al. (2024) are still apparent. Nonetheless, leveraging GPT for issues identified explicitly within the context of quality self-inspection in *Swedish* construction projects (like the "check listing" and a reduction in the clients' involvement in the process, as described in the Introduction), has not been investigated yet. In the latter case, it could be expected that, to an extent, similar opportunities, and challenges as the above should apply – but with a strong contextualization come much more specific considerations, which would require dedicated investigation.

Empirical insights

Corroborating the background studies presented earlier, a central challenge highlighted by our previous projects is that research-based knowledge of quality assurance and self-inspection is limited. Moreover, there are examples in practice where the relevant actors do not know what should be included in a self-inspection procedure, or what a verified self-inspection is. Developing relevant self-inspection lists for specific projects can also be challenging; self-inspection that is not project-adapting can make the control procedure and experience feedback ineffective.

Furthermore, client organizations that do not have tools, knowledge or a process for active quality control may need help addressing queries about construction technology, material selection, standards, and regulations, as well as getting proposals for solutions to technical challenges, analyzing commonly occurring errors and defects, and proposing effective (self-)control.

Designers and contractors may face similar challenges with every new project, and doing this in a valuable way usually requires a review and analysis of previous experiences. Finally, a proposal for self-inspection must be specifically adapted for the project at hand at least up to a requisite point. It has been observed that, normally, clients approve of time allocated for self-inspections, but this time often ends up being utilized in other activities due to the lack of planning skills. This may even mean that quality self-inspections are maybe considered as "non-value-adding" activities by some actors and are thus not prioritized.

Therefore, developing and implementing a solution to the challenges above can accelerate both the interest and understanding of self-inspection as an aid in value creation within the Swedish context. This could result in a construction sector where the customer receives the product they ordered, and the designers and contractors feel professional pride and commitment when delivering projects of high quality.

This ambition has guided our development process so far, which has already resulted in a prototype of a cloud service for quality control. A well-structured system can have a critical impact on the generation of project specific prompts and self-inspection lists. In this vein, the system should be able to use multiple and reliable data sources (with Swedish examples including BBR, Säker Vatten, GVK, PBL, the clients' own local data sources, etc.) to add context to the prompt and list generation. Letting the system interact with such data sources (e.g., by pulling the relevant data for a specific query) will significantly increase the efficiency of content generation. However, AI as such, least of all GPT, has not been part of this platform up until the latest (ongoing) project. During the latter, we have identified that implementing a GPT AI layer on top of the existing cloud service prototype, can potentially help addressing the aforementioned client needs (especially with regard to knowledge requirements for getting value out of self-inspection reports) in an educational and intuitive way. Moreover, it can also help with time savings for contractors, in relation to retrieving lessons learned from previous experiences and adapting the self-inspection template per project for contextualizing the work ahead.

Therefore, implementing GPT AI in the existing cloud service prototype can potentially not only increase the service's area of implementation, but also increase user value. Moreover, communication among the relevant stakeholders can be improved, and a new type of quality data (incl. textual data in queries) can be collected and analyzed. This insights can also be supported by investigating the way currently available GPT models are utilized to explore possible areas of use. Depending on the case, the models have been trained in large datasets, thus becoming suitable for a range of different tasks – which are, however, interrelated within the domain of the use case. In addition to answering questions and generating content, GPT systems can also analyze text, assess probabilities and relevance, suggest improvements, explain complex contexts, and suggest best practices.

As probably the most popular GPT language models, OpenAI's various versions of ChatGPT are trained on vast datasets connected to multiple topics, in order to generate text and answer user queries in a human-like manner. ChatGPT has only been publicly available for a short time, but interest has grown rapidly. This may indicate that, even in niche services, there is a high demand based on the GPT technology. The cloud support for the improvement of quality self-inspection in (Swedish) construction projects can be considered such a niche service with, as of yet, no use cases featuring the implementation of a GPT. Therefore, the uniqueness of such an implementation should not only lie in the implementation of the GPT itself, but in the value that the GPT along with the cloud service and its infrastructure can create for the users. It has been ascertained that by implementing GPT AI in the intended way, the cloud service has the potential to become very attractive to clients, designers, and contractors, and create value for them when engaging in quality assurance and self-inspection through the service.

The insights above have consequently led to some crucial considerations, which in turn reflect those obtained from the literature review. In particular, the results of a potential GPT-powered cloud service should be evaluated in terms of reliability, consistency, interpretability, generalizability, and data demands and usage. Basically, the results from the language model should be interpreted as advice and recommendations that still need to be evaluated by the user – which would in turn require the user (e.g., the client) to have some competence within the field for which the GPT is used. Finally, the implementation of the GPT AI should be evaluated from an ethical perspective (e.g., regarding privacy and ownership of data), in terms of the risks involved in implementing it as a language model or NLP support, and most importantly, by considering what kind of value streams are created and for whom.

Moreover, standing inquiries have emerged in terms of the system's conceptualization, including, but not being limited to, the following:

- Simulated prompts: From where can the system get its inspiration? Is it going to be agglomerating data related to previous similar projects from the same or another client, known errors and defects, professional roles, working tasks, relevant standards on quality management (like ISO 9001:2015) and/or risk management (like ISO 31000:2018) – or a combination thereof?
- System-generated content: Could it be both the self-inspection checklists themselves (e.g., regarding HVAC installations), and, preliminarily, suggestions for the prompts leading to such checklists (which would in turn assist users with a limited knowledge on the relevant domain)?
- The web app perspective: What will each professional role's experience be when using the system? How may the system's interface and content be adapted for the needs of the designers and contractors (who, based on own experience, may anticipate certain quality problems and self-inspection requirements in the project at hand), or the clients (who may not know and be able to predict quality problems that may emerge)?

Addressing the aforementioned insights, considerations, and standing inquiries is still a work in progress. Nonetheless, the proposed concept described in the following section can act as the relevant basis.

Conceptual design

In this section, we will frame the concept of our proposed GPT-based cloud quality self-inspection service for clients, designers, and contractors, based on the context described in the Introduction and the insights and considerations derived from our literature review and empirical project work.

First, the process graph in Fig. 1 (see next page) conceptualizes the interaction of the system's workflow within a project use case, with the different professional roles of the users who intend to use it. In particular, the process is initiated with the client creating a project, by inputting attributes like the project's name and number, sub-projects (i.e., processes connected to either planning/design or construction) and their names (e.g., SP01 Planning, UP02 Production), and dates for self-inspections (also shared with the designer and/or general contractor via emails). Then, the project is kicked off in the app and an invitation is automatically sent to the designer and/or general contractor. After the latter accept the invitation, their work in the project starts by creating a discipline list related to each sub-project, which can either be selected from a drop-down list, or defined by the user. Examples of such disciplines can indicatively include HVAC, plumbing, or electrical system installations. Then, they can invite other users as the lead of one or more of the disciplines. The leads can then create quality self-inspection checklists, either by themselves or by inviting more users to collaborate. Finally, the leads and their invited users (if any) create checks and complete them; with this completion, a progress report is generated into a PDF file, which can then be shared or downloaded.

Then, in Fig. 2 we schematically represent the concept of how GPT should work in the background for the realization of the platform's process steps described previously. Specifically, we show how the system can potentially build its prompts and generate its suggested checklists and reports by interacting with the user, utilizing relevant SQL and Vector databases for relational creation, storing, updating, and retrieval of data, using auxiliary tools like web search, and, primarily, calling and retrieving data from the LLM through its API. The content generation depends on the user's role, the databases used, and the training of the LLM informing the GPT. Over the graph itself, we include the problematization about whether the user input should follow a different generation rule depending on the user's profession, i.e., whether it should be role-based generation (potentially more suitable for designers and/or contractors) or risk-based generation (namely, returning risk analyses based on project description, which is potentially more suitable for clients). Resolving this problematization is still a work in progress, as, for example, we have so far not engaged in correlating potential risks with the presence of quality defects. However, it can be reasonably assumed that it will not affect the general structure of the concept, but rather the content of the prompts, the suggested lists, the informing databases, and even the LLM.

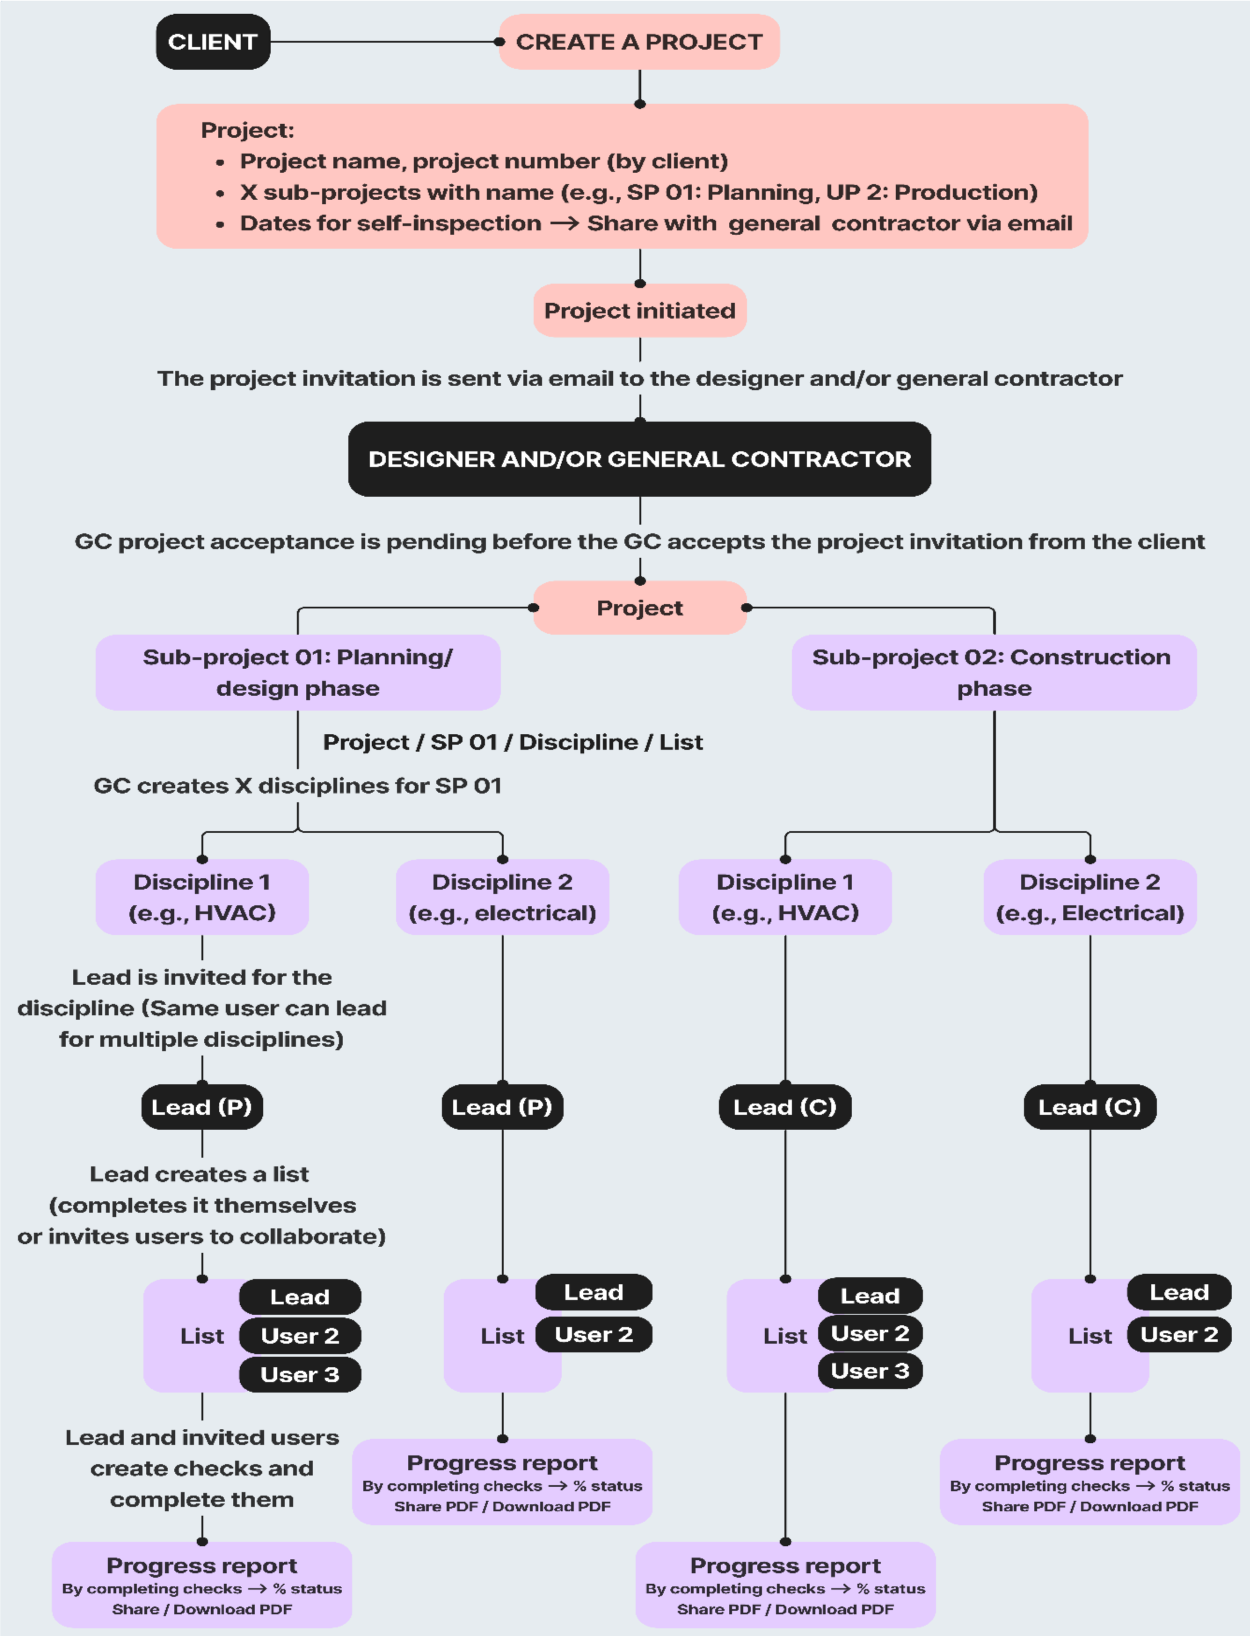

Figure 1: Interaction of the proposed system's workflow with the different professional roles using it

To further enhance the understanding of how the GPT would interface with the user, we offer the following interaction example connected to the project description analysis step:

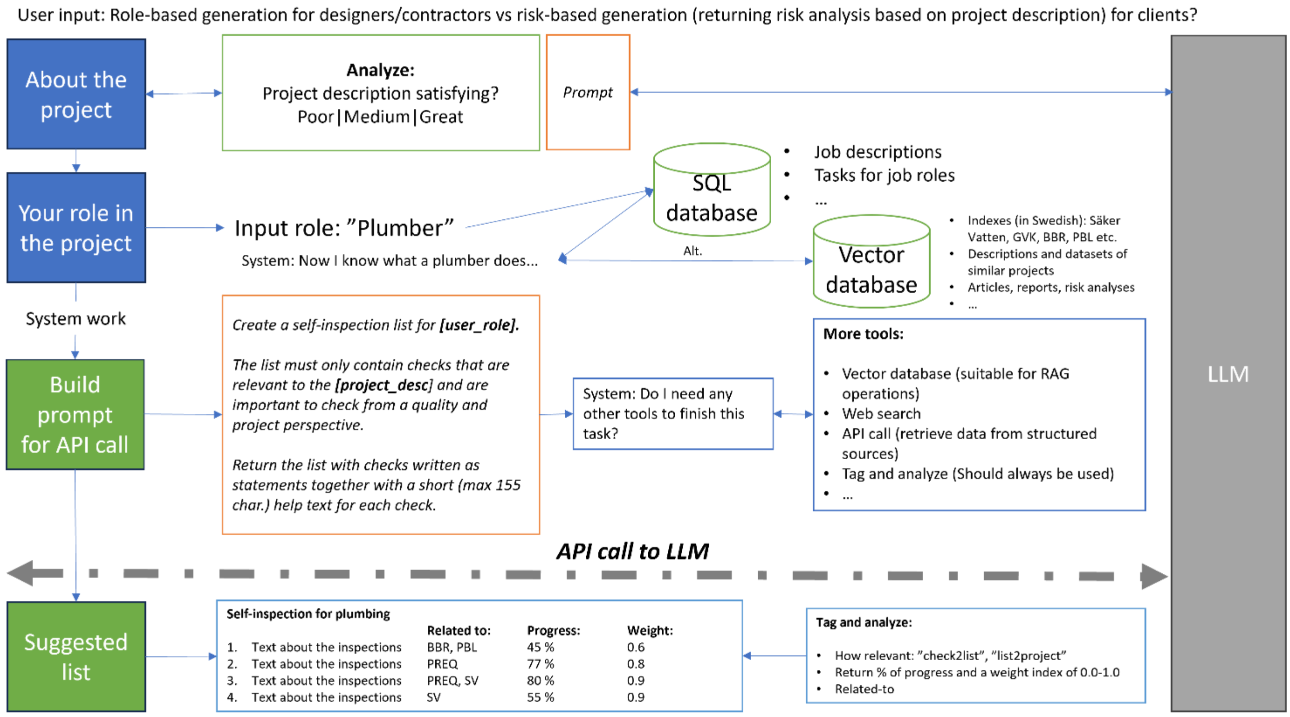

Figure 2: Schematic representation of how GPT should work in the background for the realization of the platform's process steps

You are a semantics and text analyzer, and your task is to understand the meaning of a given text and analyze it.

[text start]

A construction project has been initiated, which involves the raising of a new multi-story residential building commissioned by KKVC. This development will house 50 apartments and will feature comprehensive HVAC and electrical installations to ensure optimal conditions for future residents. The design aims to deliver comfortable, modern living spaces that meet current housing demands. Specific details about the project's size, budget, timeframe, and phases have not been provided, but the core focus will be on delivering a residential building with high-quality internal systems for heating, ventilation, air conditioning, and electrical services.

[text end]

Analyze this text and grade it. You should specifically look for these components:

- *How well does the text describe the project in general?*
- *Is there information in the text about the project budget?*
- *Is there information in the text about the project timeframe?*
- *Is there information in the text about the project and the construction phases involved?*
- *Is there information in the text about the client?*
- *Is there information in the text about the disciplines included in the project?*

Consider all questions above and then grade the text with a qualitative characterization of being Poor, Medium, Great, where:

- *Poor means that the text includes little information addressing the questions above.*
- *Medium means that the text includes a reasonable amount of information addressing the question above.*
- *Great means that the text includes a very adequate amount of information about the project and answers all of the questions above.*

Only return your score and a one-line piece of advice on how to improve the text to get a higher score (i.e., how to provide more information addressing the question above).

In short, Fig. 1 represents a simplified process flow of the cloud service concept, while Fig. 2 summarizes the functionality of the added GPT layer further empowering the service's infrastructure. These schemas are not to be considered separately, as they jointly constitute the concept of our proposed cloud-based service.

Discussion and conclusions

It has been documented that flaws in the way quality self-inspections are practiced can contribute to the recurrence of quality defects in Swedish projects. Addressing this through improving the self-inspection process itself has scarcely been the focus of relevant research. Therefore, in this paper we address the research question of how we can improve quality self-inspection in Swedish construction projects, by proposing the concept of a cloud quality self-inspection service for clients, designers, and contractors. This service is conceived to leverage generative pre-trained transformer (GPT) AI to access, retrieve, share, and create content (in the form of prompts and checklists) about relevant project knowledge and quality issues, on the basis of the understanding that professionals enacting quality controls using GPT can be provided with a much larger knowledge basis for planning and executing quality inspections.

The GPT AI support is expected to help clients, designers, and contractors to address inquiries and generate content for control plans and self-checklists. In addition, this AI could potentially help in calculating the probability and relevance of control plans and self-inspections, as well as suggesting improvement measures and best practices. The effects of this are that the client, designer and contractor can get a tool where qualitative (aggregated knowledge) and quantitative (the number of answers and suggestions) help is available in a cloud service throughout the project. It is even envisioned that, through further development, the users will, through some clicks in the app, get a proposal for a control plan together with a risk assessment and a list of quality-critical elements for both planning and execution. That foundation would be critical when developing functional requirements and requesting documents, as clients, designers and contractors can enter some brief information about the current project and get suggestions for self-checks based on the most quality-critical work steps.

The expected benefits of the cloud service include the addressing of client needs with regard to knowledge requirements for getting value out of self-inspection reports in an educational and intuitive way. Moreover, large time savings for designers and contractors can be potentially manifested, especially in relation to retrieving lessons learned from previous experiences and adapting the self-inspection template per project for contextualizing the work ahead. These benefits can primarily be achieved by having the GPT access, retrieve, share, and create content about project knowledge, experiences, known quality defects, and best practices. The aggregated knowledge to which the language model can potentially have access is in itself almost priceless.

Nonetheless, this research has several limitations. At its current stage of development, our proposed concept is still a work in progress, comprising an existing cloud service base but not a fully formed GPT layer yet. As such, it does not wholly address ongoing challenges connected to, among others, the GPT learners' limited domain knowledge, the over-reliance on the users' analytical skills to interpret and identify potential shortcomings in the content produced by the learner, the results' accuracy, generalizability, and interpretability, the potentially high cost of dedicated integration, non-updated regulations on GPT implementation, and possibly unethical data use. Moreover, there are yet not fully elaborated design considerations related to the knowledge requirements of the system's simulated prompts, the substance of the system-generated content, and the service's different functionalities and interfaces depending on the role of the user accessing it. Furthermore, measures guaranteeing the integrity and quality of the data and information processed by the GPT have not been considered yet. Using the proposed system demands specialized knowledge and expertise, and as such it must be ensured the GPT operates not merely as a linguistic transformer but as an intelligent, knowledge-based quality assessor. Finally, capabilities of assessing images (e.g., of hand-written reports), and data and/or accessor bias have not yet been considered.

Future work on the system will thus comprise, among others, the robustification of the concept for addressing the aforementioned challenges, the development and integration of the GPT layer within the cloud service base (incl. any needed APIs and user interfaces), and several rounds of testing, validation, and re-development, in order to iron out any weaknesses in the system's functionalities (incl. analyzing documents for quality against a human accessor). It is also critical to ensure the repeatability of the application, by comparing different LLM versions and vendors for the suitability informing the GPT layer of the proposed system. The ambition is that, afterwards, the cloud service will be available to all users regardless of geographic or economic conditions. Such an availability is expected to contribute to a more equal social development, as everyone would get the same opportunity and access to the service.

EXPLORING DEEP GENERATIVE MODELS IN BUILDING DESIGN

Soheila Kookalani[1], Erika Parn[1], Ioannis Brilakis[1],
Ning Pan[1], Mudan Wang[1], Hamidreza Alavi[1]

[1]Department of Engineering, University of Cambridge, Cambridge, UK.

Abstract

The complex and time-consuming nature of building design necessitates meticulous attention to detail and adherence to principles. Automation in the design process is crucial with a growing demand for innovative and sustainable structures. This review explores the transformative impact of integrating deep generative models into building design, showcasing their ability to generate realistic 3D models, layouts, and structural designs. These models address challenges in architectural design and sustainability assessment, enabling generative design and energy-efficient building design. The review suggests potential solutions and highlights the role of the models in enhancing sustainability, cost-efficiency, and creativity in the built environment.

Keywords: Design automation, Deep generative models, Generative adversarial networks, Variational autoencoders, Reinforcement learning

Introduction

The building industry faces a critical challenge in enhancing the efficiency, cost-effectiveness, and sustainability of design processes in the built environment. There is an urgent need for research and development focused on integrating automation into design processes to address this challenge (Bourahla et al., 2022; Rigger et al., 2018). The paramount importance of streamlining design procedures, reducing time and costs, and increasing productivity necessitates a thorough investigation of traditional design methodologies.

The potential for the building industry to significantly decrease design timelines and environmental impact underscores the urgency of addressing this issue. In this context, design automation emerges as a promising solution, utilizing computer capabilities to quickly produce diverse design options that meet complex objectives. Therefore, designers can evolve and refine designs efficiently, minimizing material consumption and enhancing efficiency (Karan and Asadi, 2019; Xiang et al., 2021, 2020a, 2020b).

Recent advancements in artificial intelligence (AI) and intelligent optimization algorithms have led to the development of new generative design (GD) algorithms and systems. Intelligent optimization, with its ability to find optimal solutions that maximize or minimize specific objective functions, is ideal for structural design purposes.

The integration of AI techniques in the building industry has been steadily growing (Kookalani et al., 2022a, 2022b, 2021; Kookalani and Cheng, 2022, 2021a, 2021b), with the adoption of GD methodologies and AI-driven optimization techniques poised to transform how structures are designed, constructed, and operated. Deep generative models (DGMs) significantly impact GD by streamlining processes, reducing errors, and enhancing design possibilities.

This paper aims to extensively examine DGMs and their role in optimizing structures. The study highlights DGM applications in the building design industry, emphasizing their ability for intelligent optimization. Complex algorithms enable architects and engineers to efficiently explore design alternatives, providing opportunities for real-time feedback. This allows designers to make informed decisions and create structures that are not only aesthetically appealing but also functionally efficient and sustainable.

Methodology

This section outlines the methodology employed in conducting the literature review for this paper, which delves into the application of DGMs in the field of building design. Specifically, the focus lies on exploring DGMs, which encompass GANs, VAEs, and RL techniques. A systematic search was conducted within the Web of Science Core Collection database to identify relevant scholarly papers. The search query employed the keywords ("deep generative models") AND ("architecture" OR "building" OR "structural engineering") AND ("generative adversarial network" OR "variational autoencoder" OR "reinforcement learning"). The search was constrained to categories related to architecture and civil engineering, yielding 34 initial papers. Additionally, supplementation from the references of these papers led to the inclusion of 55 relevant papers for review.

Deep Generative Models (DGMs)

GD supported by AI techniques has emerged as a transformative force in reshaping the landscape of architectural and engineering practices. This synthesis of GD principles with the power of AI, particularly DGMs, holds great promise for optimizing structures and steering the construction industry towards a more sustainable future.

DGMs, encompassing models like generative adversarial networks (GANs), variational autoencoders (VAEs), and reinforcement learning (RL), play a pivotal role in the automation of GD and analysis processes. Diagrams of these methods are presented in Figure 1. They utilize the capabilities of AI algorithms to facilitate the exploration of complex design spaces, generating efficient and aesthetically pleasing solutions. Notably, DGMs streamline the analysis and design of structural members, eliminating the need for extensive manual iterations by structural engineers.

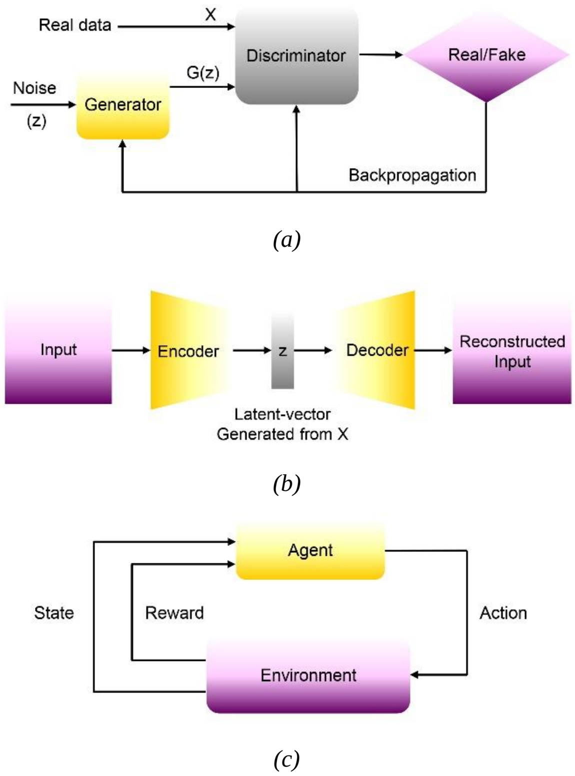

Figure 1. DGMs: (a) GAN; (b) VAE; (c) RL.

The integration of grid search accessible hyperparameters enhances the effectiveness of deep learning (DL) models. This integration enables engineers to anticipate and determine optimal performance levels with greater accuracy and efficiency, contributing to the advancement of automated GD and analysis (Torky and Aburawwash, 2018).

Several studies exemplify the application of DGMs in the field of automated GD and analysis. Yoo et al. (Yoo et al., 2021) propose a DL-driven computer-aided engineering system for conceptual design, demonstrating enhanced efficiency in structural engineering. Steuben et al. (Steuben et al., 2016) focus on AI-driven optimization of geometry partitioning for 3D printing, showcasing the potential for efficient prefabrication. Li et al. (Li et al., 2023) introduce a process for optimizing clash-free rebar design through the combination of graph neural networks (GNN) and exploratory genetic algorithms (GA).

DGMs, such as GANs, VAEs, and RL, empower architects to streamline their workflow and explore innovative design possibilities efficiently. These models find applications in indoor scene synthesis, conceptual designs, floor plan generation, architectural style identification, and architectural drawing recognition. Notable advancements include single-image 3D reconstruction and the utilization of denoising autoencoders for completing 3D shapes. Higharc, a company employing AI, utilizes DGMs for diverse architectural plans, utilizing tools like Finch that integrate machine learning (ML) and DL for conceptual designs and plan generation within the architecture field.

In summary, GANs, VAEs, and RL have improved automated GD and analysis in the building industry. GANs focus on data generation, VAEs on data compression and generation, and RL on training agents for sequential decision-making. These models offer opportunities to enhance structural analysis, optimize geometry and material distribution, and foster innovative architectural designs. The integration of DGMs into building design processes holds significant potential for advancing sustainable and visually appealing structures, aligning with global efforts to address environmental concerns, particularly in the context of smart cities and carbon emission mitigation. The continued evolution of DGMs promises to shape a future where AI-driven GD is a fundamental element of architectural, engineering, and construction practices.

Generative adversarial networks (GANs)

GANs have emerged as a powerful DL algorithm with widespread applications in generative modeling across diverse domains, encompassing image, video, and audio generation. Wu et al. (Wu et al., 2022) conducted a comprehensive review, elucidating the diverse applications of GANs in addressing complex challenges within the built environment. However, they highlighted a shared obstacle within this domain, namely the scarcity of meticulously curated datasets tailored for issues encountered in the built environment.

The GAN architecture fundamentally comprises two pivotal components: the generator and the discriminator. The generator is tasked with crafting new data instances replicating the training dataset, guided by feedback from the discriminator. On the other hand, the discriminator plays a crucial role in distinguishing real data from the training set and data synthesized by the generator. This adversarial interplay contributes to the overall learning process of GANs, with the discriminator offering critical feedback on the quality of the generated output.

In the realm of architecture, GANs have catalyzed a significant transformation, automating the generation and design of diverse architectural elements. This includes facades, interior layouts, building masses, and floor plans.

Notable examples such as ArchiGAN, House-GAN, and House-GAN++ showcase the expertise of GANs in generating fully furnished architectural plans and automated house layouts (Nauata et al., 2021, 2020), Architectural constraints are utilized, allowing architects to transform generated layouts into physical floor plans, exemplifying the practical applications of GANs in architectural design, as shown in Figure 2.

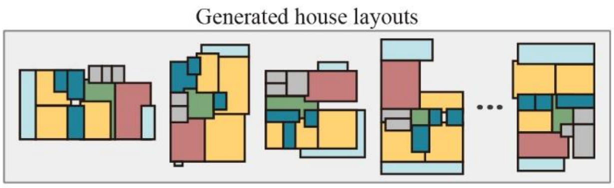

Figure 2. Automatically generating multiple house layout options by House-GAN (Nauata et al., 2020).

Subsequently, Nauata et al. (Nauata et al., 2020) illustrated a comprehensive analysis of failure and success instances, aligned with the ground-truth data, in their user study, as depicted in Figure 3. The first failure example appears unusual as a balcony is only accessible through bathrooms, and a closet is situated within a kitchen, while the second failure example seems odd due to a kitchen being divided into two disconnected spaces.

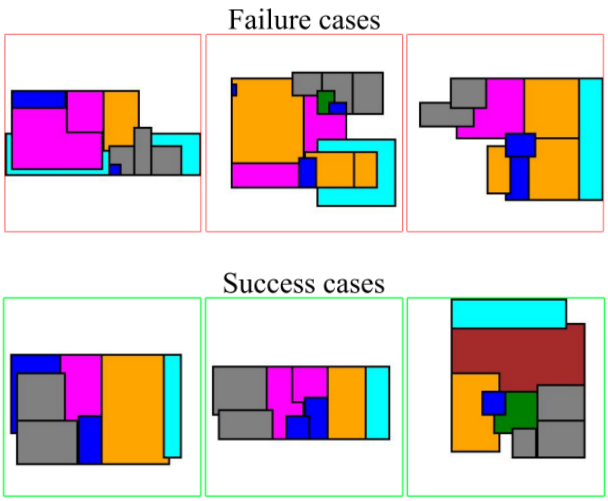

Figure 3. Failure and success examples by House-GAN from the user study (Nauata et al., 2020).

Expanding beyond conventional design realms, GANs have been employed in intelligent shear wall structure design (Zhao et al., 2023) and autonomous architectural sketch design (Qian et al., 2023, 2022). The versatility of GANs is further evidenced by their application in automating the design of shear walls, beams, and slabs in a two-dimensional plane (Liao et al., 2021; Lu et al., 2022; Zhao et al., 2022). Innovative approaches such as TxtImg2Img (Liao et al., 2022), modal expansion of reticulated shells (Zhang et al., 2023), and modular building plan creation (Ghannad et al., 2021) underscore potential of GANs to transform structural design processes, offering practical solutions in the building and construction industry.

In summary, the landscape of GANs in building and structural design is dynamic and expansive. Open-source repositories, including pix2pix, SEASAME, CycleGAN, StyleGAN, AttnGAN, and GraphGAN, further exemplify versatility of GANs in addressing specific challenges across various fields, including construction and building industry. The continued evolution of GANs and their innovative applications underscore their potential to reshape and streamline complex design processes, fostering efficiency and innovation in the built environment.

Variational autoencoders (VAEs)

VAEs have emerged as a prominent class of DGMs, garnering significant attention across various ML domains. Their success, demonstrated since their introduction in 2013, stems from their ability to address limitations faced by traditional autoencoders, particularly in sampling realistic latent vectors due to the sparsity of real data distribution in the latent space.

A fundamental characteristic of VAEs is their integration of regularization techniques to mold a well-organized latent space during training. VAEs introduce a probabilistic sampling approach in the latent space unlike conventional autoencoders, as proposed by Kingma and Welling (Kingma and Welling, 2013). The encoder of a VAE produces mean and variance values, enabling the sampling of latent vectors before decoding. The incorporation of a Kullback–Leibler divergence loss ensures a predictable latent space distribution, addressing the sparsity issue encountered by traditional autoencoders.

In the realm of deep neural networks (DNNs), VAEs have found particular utility in generative architectural designs, specifically in 2D and 3D applications. The regularization techniques employed by VAEs facilitate the creation of well-structured latent spaces, enhancing the generative process. This capability has been exemplified in the work of Wu et al. (Wu et al., 2019), who introduced an encoder-decoder network algorithm for generating floor plans, effectively enforcing room location constraints. Furthermore, Mirra and Pugnale (Mirra and Pugnale, 2021) utilized VAEs to generate topological variations of shell structure forms, highlighting the adaptability of VAEs in diverse design spaces. In addition, Danhaive and Mueller (Danhaive and Mueller, 2021) developed a methodology using conditional variational autoencoders within a performance-guided design exploration framework to construct advanced latent variable models, enabling the representation of intricate design spaces in lower-dimensional subspaces optimized for performance-driven outcomes, as shown in Figure 4. This study demonstrates that design subspace learning offers a promising solution to overcome inherent limitations in current computational design methods, providing a more intuitive and effective interface for human designers to navigate complex design spaces, thus facilitating the broader adoption of performance-informed design processes.

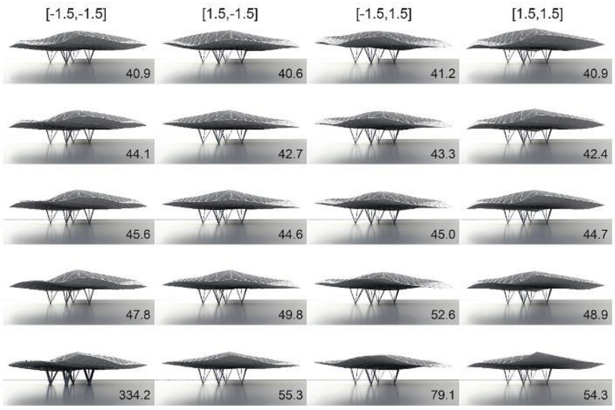

Figure 4. Morphological and performance evolution of designs in the latent space (Danhaive and Mueller, 2021).

In the context of unconditional 3D shape synthesis, VAEs exhibit significant potential (Soltani et al., 2017). Notably, they have been successfully applied to create meshes for modeling faces and human bodies, showcasing the versatility of VAEs in specific domains (Tan et al., 2017)**.** The ability to condition VAE training on design constraints or user preferences parallels the approach taken with GANs. However, VAEs possess an inherent advantage with a latent space that already exhibits some degree of structure. Researchers have developed conditional variational autoencoders (CVAEs) to enhance interpretability and control. CVAEs extend conventional VAEs by incorporating a conditioning vector as input to both the encoder and the decoder, facilitating the integration of design constraints and user preferences in the generative process (Danhaive and Mueller, 2021)**.**

In summary, VAEs have proven to be a powerful tool, offering solutions to challenges faced by traditional autoencoders. Their success in various ML applications, coupled with their adaptability to different design domains, underscores their significance in shaping the future of generative modeling.

Reinforcement learning (RL)

RL distinguishes itself from other DGMs by its unique ability to learn in an unsupervised manner, obviating the need for a pre-existing dataset. Instead, RL operates through trial-and-error interactions between an actor and an environment, with the goal of maximizing rewards accrued through decision-making and action-taking (Kaelbling et al., 1996). The central objective of the actor in RL is to optimize the total reward obtained, casting RL as a form of optimization process.

An early fusion of DL and RL was pioneered by Mnih et al. (Mnih et al., 2015), who integrated DL with Q-learning. Q-learning revolves around learning the state-action value function, known as the Q-function, estimating the potential reward associated with a specific action taken in a given state. The introduction of convolutional neural networks (CNNs) in this paradigm enabled the learning of the Q-function.

In the realm of design, RL unfolds as a sequential process, iteratively modifying or generating designs through a series of actions. The quality or performance of the resulting design serves as the reward signal, effectively acting as the environment for RL. While RL eliminates the need for a conventional dataset, it heavily depends on meaningful and reliable reward signals, often necessitating a high-fidelity simulation environment. A key advantage of RL over GANs and VAEs is its flexibility in defining the reward function based on any objective, which need not necessarily be differentiable. In contrast, GANs and VAEs rely on gradient-based optimization and require any added objectives in their loss functions to be differentiable.

In engineering design, RL has been successfully applied to address inverse design problems, seamlessly combining learning with design optimization. Dworschak et al. (Dworschak et al., 2022) proposed a comprehensive approach for design automation using RL for parametric computer-aided design (CAD) models. Cui et al. (Cui et al., 2012) employed Q-learning for design optimization, while Yonekura and Hattori (Yonekura and Hattori, 2019), and Lee et al. (Lee et al., 2019) implemented double deep Q-learning (DQN). Sun and Ma (Sun and Ma, 2020) extended four well-known exploration techniques in RL to generate multiple solutions. Shi et al. (Shi et al., 2020) introduced an innovative algorithm that combines RL with off-policy monte-carlo tree search for generative floor plan design.

Jeong and Jo (Jeong and Jo, 2021) presented a novel RL-based method for automated reinforced concrete (RC) beam design. They utilized the deep deterministic policy gradient, employing CNN function approximators. They demonstrated that the RL agent can successfully create continuous beam members with design quality comparable to optimized designs, all without requiring an iterative process. Additionally, a clearly delineated collection of reward functions is essential for the success of the suggested approach in expanding its application in structural design automation. This entails exploring a broader range of cost reward functions.

Liu et al. (Liu et al., 2020) proposed a novel approach employing Q-learning-based multi-agent RL for clash-free rebar automated designs in practical applications involving reinforced concrete structures. The outcomes of the simulation regarding success rates and average time required for rebar designs in RC members revealed that the suggested framework has the potential to substantially diminish engineering duration (up to a 90% reduction) and prevent spatial conflicts among rebars. Hayashi and Ohsaki (Hayashi and Ohsaki, 2021) introduced a novel approach combining RL and metaheuristics for automated optimal cross-sectional design of planar frame structures. It was demonstrated that the optimal simulation outcome improved after completing 100 and 1000 training sessions, successfully reducing the cross sections while adhering to the constraints. Maghami and Hosseini (Maghami and Hosseini, 2022) innovatively incorporated deep reinforcement learning (DRL) to facilitate the automated reverse engineering of layered phononic crystal beams, as depicted in Figure 5. It was demonstrated that the algorithm successfully generated appropriate geometry. Consequently, the integration of RL into engineering design research offers promising solutions for addressing complex optimization challenges.

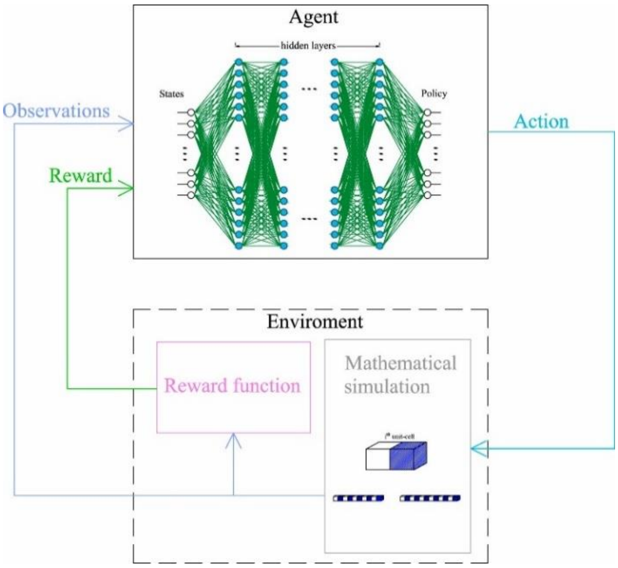

Figure 5. Framework of automated design of layered phononic crystal beams through DRL (Maghami and Hosseini, 2022).

Methods Comparison

GANs, VAEs, and RL are prominent techniques in artificial intelligence, each serving distinct purposes. GANs are primarily geared towards generating realistic synthetic data such as images, audio, and text by learning the data distribution. VAEs, on the other hand, focus on learning latent representations of data, enabling generation, reconstruction, and providing a measure of uncertainty. RL is utilized for sequential decision-making tasks, where an agent interacts with an environment to achieve specific objectives, learning through iterative trial and error processes.

In terms of implementation, GANs consist of two networks: a generator and a discriminator, trained concurrently in a minimax game setup. The generator fabricates samples while the discriminator evaluates their authenticity. VAEs comprise an encoder and a decoder, where the encoder maps input data to a latent space and the decoder reconstructs the input from sampled points. RL involves an agent interacting with an environment to learn a policy maximizing cumulative rewards through exploration and exploitation techniques such as Q-learning and policy gradients.

Applied scenarios highlight the diverse applications of each technique. GANs find utility in generating realistic images for data augmentation, style transfer, and image-to-image translation. VAEs are applied in tasks like image denoising, semi-supervised learning, and generating novel data samples. RL is widely used in robotics, game playing, recommendation systems, autonomous vehicles, design automation, and natural language processing tasks. However, each technique also faces design challenges; GANs may suffer from mode collapse and training instability, VAEs often produce blurry samples, and RL is susceptible to issues like high sample complexity and reward sparsity. Overall, the choice among GANs, VAEs, and RL depends on the specific requirements and constraints of the problem being addressed.

Challenges, Opportunities, and future work

DGMs have emerged as a transformative paradigm in the building and construction fields, offering efficient and user-friendly alternatives to traditional experience-based processes. The exploration of DGMs applications, methodologies, and optimization potential has highlighted a set of challenges and opportunities crucial for its widespread implementation and impact.

The effectiveness of DGMs heavily relies on high-quality and relevant data, posing challenges due to fragmentation, inconsistency, and proprietary nature. Addressing this necessitates efforts in establishing data standards, promoting collaboration, and developing robust data acquisition and preprocessing techniques. Utilizing sensor technology, building information modeling (BIM), and data analytics can enhance data sets, empowering GDM models to generate innovative and optimized solutions tailored to specific project requirements.

Incorporating performance evaluation is crucial for practical DGMs application. Challenges in fidelity, cost, and differentiability need attention. Balancing accuracy and computational cost are essential, and advancements in surrogate models, self-supervised data augmentation, and multi-fidelity modeling show promise in addressing these challenges. Future developments aim to create faster and more accurate evaluation methods.

DGMs involve complex algorithms and optimization processes demanding significant computational resources. Overcoming this complexity requires efficient algorithms, parallel computing techniques, and optimization strategies. High-performance computing architectures, such as tensor processing units and graphics processing units, have accelerated DGM workflows, making tools more accessible. Future advancements, like quantum computing, hold potential for even more sophisticated DGM techniques. Quantum computing holds promise for improving various fields, due to its ability to process vast amounts of data and perform complex calculations at speeds far beyond classical computers. It could potentially enhance DGM techniques by offering more efficient algorithms for data generation. This could lead to the creation of more realistic and higher-quality synthetic data, benefiting applications ranging from data augmentation to simulating complex real-world scenarios.

Current DGMs tend to imitate existing data, impeding the generation of creative or novel designs. Improvements can be achieved by enhancing models like creativeGAN and introducing new features into typical designs. Creative adversarial networks (CAN) can encourage the production of surprising and novel design elements, fostering more human-like creativity in GD.

As DGMs become more complex, the need for interpretability grows. Explainable AI techniques, visualization tools, and interactive interfaces are being developed to explain black-box models. Ensuring interpretability in DGMs enhances collaboration, decision-making, and the adoption of optimized designs.

The potential of DGMs lies in solving complex problems, necessitating collaborations between data scientists, AI experts, and construction professionals. Interdisciplinary collaborations ensure a deep understanding of domain-specific principles and constraints, leading to more sustainable and impactful designs aligned with industry standards and project requirements.

The convergence of AI and design has brought about a paradigm shift in DGMs with the advent of language models. These models offer new possibilities for exploration, diverse design generation, and innovation. However, challenges include designs that may not consider practical constraints, requiring human oversight. Responsible and ethical use of language models is crucial for ensuring designs align with safety, inclusivity, and environmental considerations in DGMs.

Conclusions

This review has delved into the expansive realm of DGMs within the architectural design sector, highlighting their promising yet intricate capabilities. While our exploration has extended the ways in which DGMs can potentially streamline design processes and foster innovation, it is crucial to underscore that the transformative potential of DGMs is derived from both established applications and forward-looking possibilities, rather than conclusive proof across the board.

The discussion on the utility and flexibility of DGMs indeed illuminates a path toward significant advancements in design methodologies, underscored by examples of efficiency gains, creative enhancements, and sustainability impacts. However, the journey from potential to proven impact is paved with challenges including data quality, performance evaluation, computational complexity, creativity limitations, interpretability concerns, and the imperative need for interdisciplinary collaboration have been identified. Recognizing these challenges is crucial for charting the course of future research endeavors. It is imperative that future investigations prioritize advancements in hardware capabilities and utilize the potential of language models to overcome existing barriers.

The industry can unlock the full potential of DGMs by addressing the challenges. The future trajectory of DGMs in the construction sector relies on a delicate balance between creativity, optimization, and human expertise. This synthesis has the potential to initiate a paradigm shift, fundamentally transforming the construction landscape and shaping a built environment that adeptly meets the intricate and evolving needs of society.

Essentially, as we navigate the evolving frontier of DGMs in the construction domain, it becomes evident that their impact extends beyond mere technological advancements. DGMs have the power to contribute meaningfully to the creation of adaptive and user-centric built environments, embodying a symbiosis between cutting-edge technology and human ingenuity. The collective efforts of researchers, practitioners, and stakeholders are instrumental in utilizing this potential, ensuring that the future of DGMs in construction is not only transformative but also socially responsible and sustainable. The path forward requires a clear-eyed focus on evidence-based advancements, collaborative innovation, and the responsible harnessing of capabilities of DGMs to meet the dynamic needs of society and the built environment.

UNVEILING PROSPECTS THROUGH PLATFORM-DRIVEN TRANSFORMATIONS IN MODULAR CONSTRUCTION SUPPLY CHAINS

Akila Rathnasinghe[1], Niraj Thurairajah [1], and Paul Jones [1]
[1]Faculty of Engineering and Environment, Northumbria University, Newcastle-upon-Tyne, UK

Abstract

Managing intricate supply chains (SCs) in modular construction is challenging, necessitating a nuanced approach to enhance effectiveness. This study aims to explore the potential of platform thinking—a methodology that reimagines traditional, linear SCs into dynamic, interconnected networks, aligning producers' resources with user needs, through an integrative literature review method grounded in supply chain management (SCM) theoretical perspective. Identifying four prospects for platform-induced SC reconfigurations, this study offers novel perspectives on preparing the modular sector for the platform revolution, highlighting the importance of understanding its benefits and challenges.

Introduction

Change is unavoidable, regardless of how well established a business or profession is. A new type of supply chain (SC) business model has been adopted by a wide range of businesses over the last two decades. Without gratifying much about the importance of those, it would be easy to start by thinking of companies like Apple, Uber, Airbnb, and Twitter. This new generation of companies has taken a different approach to reaching scale while meeting a wide range of client demands. For centuries, businesses operated on a pipeline SC design; they would manufacture a product and push it towards a consumer in which value had been produced upstream and consumed downstream, creating a linear value model like a pipe. Choudary (2015), on the other hand, noted that the growing connectedness of entities (as part of the globalisation), decentralised manufacturing, and the embedding of artificial intelligence have driven traditional sectors to adopt an entire new SC model.

Accordingly, many firms in a wide variety of industries are acting as a platform to facilitate producers and consumers of value around the world to connect and interact with each other in a manner that was not possible in pipe design. Traditional taxi businesses, for instance, were historically established with ownership/possession of hundreds of cabs, and passengers were needed to request the cab directly from the firm or the driver without even knowing what the rate would be. Companies such as Uber, on the other hand, are now functioning as a platform to link convertible roles (no specified roles for participants; a driver in one instance might become a passenger in the next) of drivers and passengers toward an economic transaction without even owning a single taxi for the firm itself. As a result, such platform-based firms enable externally positioned producers and consumers to trade value within the SC while also allowing them to be a part of their core business function. This shattered the long-established feature of the firm being the producer of value while enabling multi-dimensional value exchanges among many SC stakeholders, which is the primary deviation from the pipeline model.

The success achieved by various industries due to the transition from pipe to platform-enabled SC models is undeniable. By the end of 1980s, there were less than ten firms who has tried at adopting platform strategy into their SC functions. However, the Forbes Insights survey (2017) found out that 31% of organisations consider themselves top performers in platform thinking, enabling both external and internal SC stakeholders to interact with the organisation and widening the availability of the organisation's digital resources to all stakeholders (McKendrick, 2017). In 2019, it was reported that seven of the world's ten most valuable firms are based on platform-enabled models with less than two decades of existence. As a result, the advantages and potential disruption to established firms from platforms seem essentially inconceivable. Parker *et al.* (2016) rephrased Marc Anderssen's famous slogan "software is eating the world" in 2011 to highlight the massive disruption caused by software-based digitalisation in every aspect of human life as "platforms are eating the world" because software alone is insufficient with current market features: increasing interconnectivity, decentralised manufacturing, and the emergence of artificial intelligence.

As a result, the potential value that can be realised by a platform opportunity in the modular industry is unmistakable. Even though the modular industry already comprises the market attributes, platform disruption has only been examined as a feasible tool for achieving mass customisation (Bertram *et al.,* 2019). However, an investigation into current platform studies in modular construction revealed that the identification of further opportunities arising from unique SC reconfigurations induced by platform applications in modular construction has received minimal attention. Also, as Thurairajah et al. (2023) reveals, even though most production procedures in manufacturing sectors are mature and ready to use, applying these approaches blindfolded without systematically thinking about or adopting them may bring additional issues in any given context. As a result, the purpose of this study is to take the initiative in presenting on how the platform thinking may provide effective SCM within the modular construction. Thereby, this study intends to demonstrate the viability of platform-enabled SC in a modular construction setting in a methodical manner.

What is platform thinking?

Thomas, Autio, and Gann (2014) establish platforms as control and monitoring mechanisms within SCs, concentrated on shared technology, standards, and assets that confer benefits to contributors. Robertson and Ulrich (1998) present a more inclusive definition of platforms as a collection of assets—encompassing components, processes, knowledge, people, and relationships—shared among a range of product SCs. In essence, platforms constitute a unification of components and rules governing SC relationships, where components encompass software, hardware, service modules, and architectural frameworks delineating their interactions (Henderson and Clark, 1990), and rules encompass standards, protocols, and regulations organising the activities of contributors within the ecosystem (Baldwin and Clark, 2000).

The application of platform thinking to restructure a firm's SC into somewhat standardised is not a recent phenomenon. In manufacturing, it is routine to leverage past designs to improve or fix shortfalls in prior activities, resulting in the emergence of platforms as subsystems and interfaces facilitating efficient development and production of product families, such as automobiles or consumer electronics devices (Muffatto and Roveda, 2002). A fundamental objective of such platform-based new product development is to augment product variety, addressing diverse customer requirements, business needs, and technological advancements, while upholding economies of scale and scope within manufacturing processes—a concept inherently linked with "mass customisation" (Pine and Davis, 1993).

Platform thinking in construction

The advent of platform thinking in the construction sector, especially through the strategic use of artificial intelligence, digital innovation, and the standardisation of processes, marks a pivotal transition towards a more synergistic, efficient, and forward-thinking modus operandi. Studies, such as of Oprach et al. (2019), elucidate the way a platform-centric approach, augmented by AI, substantially boosts data interoperability and utilisation across diverse organisational frameworks, thus engendering an ecosystem ripe for innovation and streamlined operations within the industry. Concurrently, Jansson, Johnsson, and Engström (2014), alongside Eriksson and Emilsson (2019), lay emphasis on the quintessential role of standardisation and modular design, coupled with the implementation of process platforms, as instrumental in enhancing product delivery flexibility and efficiency. Such platforms adeptly manage consumer specifications, bolstering competitive product propositions while steadfastly adhering to a platform-centric strategy. Furthermore, Lapidus (2022) broadens this discourse to encapsulate large-scale construction ventures, where organisational and technological platforms, through the leverage of digital technologies and information modelling, optimise construction undertakings. Additionally, the discourse on platforms as pivotal in knowledge management within construction firms, as posited by Styhre and Gluch (2010), illuminates their utility as boundary objects that amalgamate functions and codify procedures—a cornerstone in the efficacious management of knowledge and the propulsion of innovation.

Yet, despite the apparent advantages and the progressive integration of platform thinking within construction paradigms, a discernible lacuna persists in its application to SCM within the domain of modular construction. Characterised by its predilection for prefabrication and assembly-line proficiency, modular construction is ostensibly positioned to reap substantial benefits from platform-centric SCM methodologies. Such an amalgamation promises not only to streamline operational processes but also to foster stakeholder collaboration, thereby paving the way for more sustainable and cost-efficient construction modalities. Yet, the existing literature lacks comprehensive analysis on the effective implementation of platform thinking in SCM for modular construction. This identified gap serves as a critical research avenue for this study, aiming to explore the transformative impact of platform thinking on SCM practices, thereby ushering in a new epoch for modular construction and the construction industry at large.

Research Method

Using an integrative review methodology, this study seeks to investigate the effect of platform thinking on the effectiveness of SCM within the milieu of modular construction. The motive for using an integrative methodology was established on its ability to foster a comprehensive discourse around ongoing challenges by combining and processing existing theories or concepts (Synder, 2019). Integrative literature reviews, whether they focus on well-entrenched or emerging subjects, vary predominantly in their synthesis approach. For recognised topics, this method involves a thorough examination of existing scholarly contributions, facilitating a critical assessment to either recontextualise or expand prevailing theories. On the other hand, for emergent fields, it envisages producing innovative theoretical frameworks or models (Synder, 2019). Following this principle, this study looked for literature, employing terms such as "modular construction," "supply chain management," "platform business models," and "platform thinking," located from authoritative databases like Google Scholar, Scopus, and Web of Science. This search yielded insights into the evolution of the platform concept across various industries and the enhancements it has spurred. This phase was succeeded by an investigation into the potential of platforms to revolutionise SCs across sectors. This led to an analysis focused on the modifications within modular SCs that accompany a successful reconfiguration from product-centric to platform-centric models.

Background

Supply chain management (SCM)

The definition of "supply chain" exhibits a greater consensus compared to the definition of "supply chain management" (SCM). While La Londe and Masters (1994) offer a straightforward perspective, viewing a SC as a "set of firms that pass materials and services forward," Mentzer *et al.* (2001) present a nuanced view, outlining it as a "set of three or more functional bodies directly involved in the upstream and downstream flows of products, services, finances, and/or information from a source to a customer" (p.4). The management of these SCs serves as a mechanism for SC components, aiming to foster an innovative mindset that creates significant value for end customers, as highlighted by Ellram (1990). In line with the reviewed literature, this study takes a stance on SCM by considering the SC as a unified entity to govern the flow of inventory from inception to destination. Additionally, it emphasises placing the sub-units of the entire SC logically for enhanced integration among inter-firm functions and strategic capabilities.

Love *et al.* (2004) articulate the intricacies of supply chain management (SCM) within the construction sector, outlining it as a network involving facilities and activities contributing customer and economic value to various functions, including design development, contract management, service, material procurement, materials manufacture and delivery, and facilities management. However, the reality of SCM in the construction industry reveals a lack of cohesion, adversarial relationships, and a project-centric mindset, hindering the optimisation of value creation (Bankvall et al., 2010). In scrutinising the underlying causes for these challenges, a paramount consideration is delving into the unique attributes of the construction industry and its project environments, which are often perceived as trailing behind other sectors in terms of clear and long-term supply relationships (Thurairajah *et al.,* 2023). Notably, Vrijhoef and Koskela (2000) highlight distinctive features in construction SCM, including converging SCs directing all materials to the construction site, project-specific configurations, and make-to-order SC relationships characterised by limited recurrence. This perspective aligns with Fearne and Fowler (2006), who argue that prevailing structural features in construction SCs are suboptimal from a production standpoint, primarily due to the inherent fragmentation and transience in supply relationships.

Modular construction and its Supply Chain (SC)

Concerning modular construction, Langlois (2002, p. 19) explains modularity as "a highly general set of principles for managing complexity. By disassembling a complex system into discrete pieces—capable of communication solely through standardised interfaces within a standardised architecture—one can obviate what would otherwise be an unwieldy entanglement of systematic interconnections." Within the construction industry, modularity manifests as the production of volumetric systems, along with sizable, prefabricated sections within a supervised manufacturing setting. Volumetric systems comprise three-dimensional modules functioning either independently or multiplicatively, contributing to the building's structural integrity (Thurairajah *et al.,* 2023). These modules, produced in a factory with all finishes (i.e., fixtures and fittings), involve least on-site installation work. Essentially, the modular construction approach entails off-site SCM, diverging from traditional on-site methodologies.

Prior to delving into the SC intricacies of modular construction, a prerequisite lies in delineating the disparities between traditional construction processes and the modular method, considering these as fundamental determinants of its distinctive nature. Notably, the design of modular buildings undergoes detailed scrutiny under the Design for Manufacture, Logistics, and Assembly (DfMA) approach, with a focus on real-world execution encompassing manufacturing, logistics, and assembly (Building and Construction Authority, 2017). Another distinction surfaces in the imperative for factory production, necessitating an early freeze on the detailed design to facilitate module production—a necessity absents in traditional construction (Thurairajah *et al.,* 2023).

Regarding the SC dynamics of modular construction, in contrast to the conventional SC, modular SC can be perceived as an intricate ecosystem encompassing firms, participants, information, and resources engaged in interconnected downstream and upstream processes and activities, culminating in value delivery within modular projects. This delineation encapsulates the fluidity of information and material flow throughout the delivery chain, spanning conceptualisation, tendering, design, procurement, construction, handover, and the operation phase of construction projects (Vrijhoef and Koskela, 2000). Given the apparent distinctions between traditional construction and the modular approach, the configuration of the supply and delivery chain in the latter departs from the former. The modular SC stages are typically concretised as design, procurement, production, logistics (encompassing transportation, buffer, and storage), and on-site installation (Luo *et al*., 2020).

Discovering Prospects in Platform-induced SC Reconfigurations

Most of today's platforms (i.e., iOS, Facebook, Google, etc.) started as successful standalone products, while some began as services or one-sided platforms. The Internet, which enables SC actors from anywhere on the globe to communicate in a matter of seconds, is primarily responsible for the transformation of products into platforms (Abdelkafi et al., 2019). On the other hand, Tiwana (2014) stated that such a transformation would be the safest alternative for product owners to establish a successful platform. Because successful products have an established consumer base, from which product owners are motivated to consider a future option to construct a platform aimed at offering a more inclusive service to consumers as a collaborative effort of multiple parties. In the current world, anytime a product is successful and one side (i.e., consumers) accepts it in droves, each of these products is driven to add a second side to grow into a platform (iPhone added App Store, Facebook added advertising, Firefox added extensions). However, as Hagiu and Altman (2017) pointed out, such a transformation for successful products is not an instantaneous process, and organisations that are not born platforms are frequently left in the dark in search of a strategy to achieve this transformation.

In the domain of modular construction, Thurairajah et al. (2023) highlights a significant evolution in SCs, extending beyond the simple delivery of modular buildings to include elements that add value, such as servitisation—focusing on operational and maintenance aspects—and customisation, which empowers consumers to influence the specifications of modular products. However, the sustainability of these evolved SCs has been questioned. Persson and Lantz (2022) argued that despite the direct advantages derived from servitisation and customisation, these practices may not ensure the long-term sustainability of modular construction firms. The financial difficulties confronted by prominent modular construction companies in the UK, such as ILKE Homes and L&G, credited to the complexities of managing diverse service offerings, increased SC complexities, and the need for dynamic adaptation strategies, reinforce these concerns, causing unease among industry professionals regarding future SCM innovations.

Addressing these challenges, this study introduces four strategic opportunities, or "prospects," for modular construction companies to adapt to and leverage in the wake of SC transformations brought about by platforms. These prospects are identified through an adaptation of Tiwana's (2014) "four lenses framework," originally developed for software development, now repurposed for the construction sector. This framework uses four distinct perspectives to dissect and comprehend the extensive production processes in the context of platform thinking. The identified "prospects" offer modular construction firms a guide for strategic adaptation and enhancement in areas such as consumer interaction, operational efficiency, service diversification, and ecosystem collaboration, as depicted in Figure 01.

Prospect 1: Horizontal supply chain collaborations.

Barrat (2004) outlines horizontal SC collaboration as the collaborative inter-firm dynamics existing among entities operating at similar SC tiers (i.e., this could be component manufacturers considering the modular context). Barrat (2004) also suggests that these collaborations hold the potential for enhanced advantages, encompassing shared risks, mutual acknowledgment, and interdependence directed at shared or industry-wide goals which could not have been achieved by a single industry player.

Accordingly, a platform requires to have at least two sides (Eisenmann *et al.*, 2006), resulting the significant SC reconfiguration within any production process. Schmalensee and Evans (2007, P.38) emphasised that the unifying factor of all platforms is that they facilitate interactions between at least two or more "distinct" groups who want to engage with and require each other but cannot initiate such interaction by the current means of. As a result, Tiwana (2014) determined that to be a true platform, two distinct parties must be offered, with the platform actively engaged as the medium for the interaction (i.e., based on that claim, ERP is a one-sided platform in which the platform owner-software developer serves the needs of the enterprise/company without interfering with or governing communications between the company and its third-party suppliers/professionals). As a result, in any product environment, if there is any chance that two or more parties might enhance their values by having someone support them in finding each other and engaging cost-effectively, then there is an opportunity for a platform to be established. By saying so, it does not imply that the interaction would be impossible to occur in the absence of a platform; rather, the existence of a platform has made such interaction simpler and less expensive by linking in ways that those parties could not directly connect (Evans, Hagiu and Schmalensee, 2006). Platforms could serve as a conduit for facilitating value-infused interactions between two or more parties.

Prospect 2: Demand-responsive supply chains.

The imperative of SC Responsiveness (SCR) has escalated, presenting paths for competition in business landscape. Formerly a conceptual abstraction, SCR has become into a strategic tool, necessitating the evolution of SCs towards heightened flexibility and responsiveness (James-Moore,1996). Accordingly, SCR is seen as the capacity of the SC to adeptly address variations (i.e., niches) in general consumer demand (Holweg, 2005). It also captures the coordination of production, inventory, location, and transportation within the business firms of SC, strategically optimising responsiveness and efficiency tailored to the relevant market dynamics.

In light of this, consumers (markets) for any product SC can be identified under two categories: core and niche markets. However, satisfying the needs of the niche group of consumers (also known as long-tails in the product market) is fairly challenging within the economics of scale in manufacturing (including modular construction) since such consumers' needs are somewhat distinct from the basic/ every-day consumers' demands (which majority of the product market) (Rogers, 2004). As a result, product owners might consider a platform solution to handle the market's long tail through smaller competitors in the industry. Such a choice by product owners to form a platform may be an alluring option to: digitise and modularise (decentralise) the production activities that are currently provided in-house; provide additional goods or services to enhance the value of the core product; bring specialised collaborators who are excelled at performing a certain activity rather than manufacturers themselves; enable smaller firms to improve their work based on producers' work without replicating it (Gawer and Cusumano, 2008).

Prospect 3: Vertical supply chain collaborations.

In contrast to the previously examined horizontal collaboration, vertical SC collaboration delves into inter-firm relationships at various levels within the SC (Barrat, 2004). This entails exploring the dynamic between suppliers and manufacturers, specifically in a modular context this could be manifested as the collaboration between component manufacturers and mega manufacturers.

coordination among business entities, industries must methodically define problems, explore available options, and forge agreeable solutions by fostering collaboration across diverse functions within the industry (i.e., in the context of the modular industry, these functions span design, planning, procurement, manufacturing, logistics, and operation & maintenance).

When a platform facilitates value-added interactions among and between two or more distinct groups, cross-functional collaboration impact (i.e., in platform literature this has been termed as network effects) define the level of value impact that every new contributor (from one group) may offer to the rest of the existing platform contributors (Tiwana, 2014).

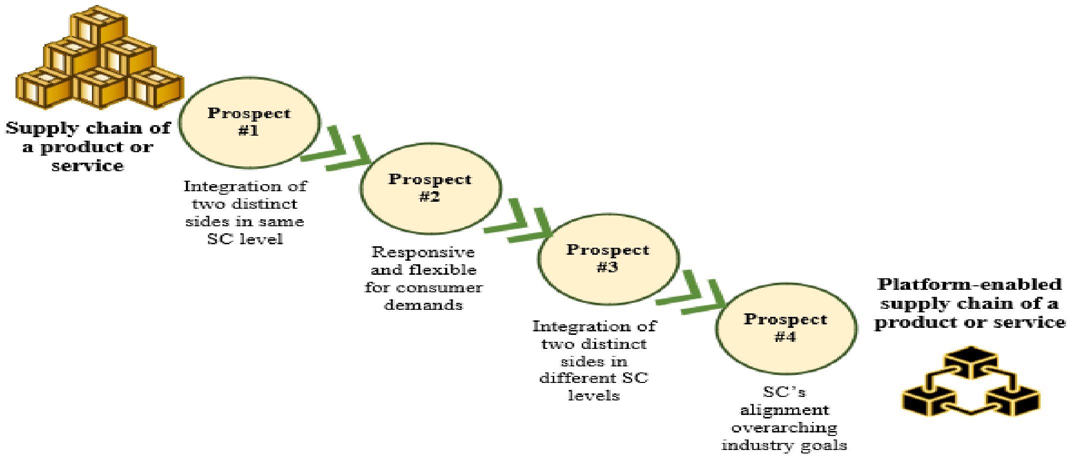

Figure 1: Four prospects due to platform-induced supply chain reconfigurations

Also, as discussed in the first prospect, a real platform should at least include two distinct parties. However, the initial inclusion of both parties by a platform owner proves unfeasible. Hence, Tiwana (2004) emphasised the importance of presenting at least one party from two distinct groupings to bring a platform to its true essence. Platform development, on the other hand, may face a "chicken-egg dilemma," in which interested parties may find a platform unappealing to join in the absence of a strong presence on the opposing side (Calliaud and Jullien, 2003). Consequently, Tiwana (2014) elucidates that if a prominent market player aligns with the platform solution, it induces other entities to join, driven by perceived prestige and the ensuing competitive advantage in their respective business domains. Once a party agrees to be corporative in the platform creation, the platform solution should include a compelling value proposition with the already recruited party to bring the other side onboard as well.

Prospect 4: Cross-functional collaboration impact.

Cross-functional collaboration within SCs facilitates a comprehensive evaluation of SC's state in alignment with industry needs. This evaluation serves as a foundation for crafting and perpetuating value through a collaborative assessment (Oliva & Watson, 2009). Beyond mere

This level of collaboration impact (network effect) might be perceived by contributors in the same group (same-side network effects) or by contributors in a different group (cross-side network effects). Tiwana (2014) emphasised the importance of a clearly established second side to produce cross-side effects rather than same-side effects because such effects would assist the platform in generating downstream sub-products (rather than just increasing the consumer base or supply rate by having more contributors on the same side) that the core market group could use to enhance their experience with the main product or service.

As a result, if any production process is transformed into a platform, the platform owner should be able to recognise that there is more than one "other side" that could inflict the most obvious cross-side network effects. Therefore, Tiwana (2014) asserted that every production or manufacturing scenario that can be observed via at least two of the impacts depicted in the four lenses (refer to Figure 01) that generate due the product's transformation into a platform.

Expected prospects due to platform-induced modular construction SC reconfigurations

Modularity in construction fundamentally transforms complex buildings into manageable, independently produced components that together constitute a unified structure. This approach, deeply embedded in the principles of mass production within controlled settings, has traditionally been recognised as a collective endeavour among various manufacturers (Langlois, 2002). Yet, recent challenges faced by modular factories, especially those related to scaling component production, necessitate a critical reassessment of these collaborative frameworks (Ethiraj & Levinthal, 2004). Such challenges not only question the efficacy of conventional collaboration in component manufacturing but also spotlight the limitations in applying modular principles in practice.

This situation highlights the necessity for a thorough reassessment of the manufacturing strategies within the modular SC, suggesting the need for a unified approach across various SC entities. However, we would like to highlight that the purpose such evaluation is not aiming to detract from the value of current alliances within the modular domain but rather to improve the collaborative efficacy of these partnerships (Brusoni & Prencipe, 2001). Within this context, the adoption of platform thinking is pivotal, promoting an integrated ecosystem of stakeholders in the modular construction SC. This approach enables direct access to a broader spectrum of component manufacturers, overcoming conventional geographic limitations (Parker, Van Alstyne, & Choudary, 2016). Such strategic unification not only streamlines procurement processes but also ensures the participation of the most appropriate contributors for each initiative.

Moreover, the modular construction industry's inherent adaptability, particularly through the use of prefabricated components, positions it uniquely to address diverse customer requirements (Baldwin & Woodard, 2009). However, the pursuit of extensive customisation within this model presents challenges, notably in reconciling the advantages of standardisation with the intricacies of individualisation. The pursuit of excessive customisation may dilute the efficiency and scalability that are hallmarks of modular construction, risking resource allocation away from broader market needs and impacting production timelines and efficiency (Thurairajah et al., 2023). Embedding modular offerings within platform-based frameworks offers a systematic method to maintain both the autonomy of individual component production and the integrity of the assembled product. This approach aligns with Tiwana's (2014) perspectives on innovation and is exemplified by Dell's successful mass customisation model, which assembles personalised products from a spectrum of supplier components (Berman, 2002).

Despite apprehensions that platforms might enable dominant entities to overshadow smaller firms, a more discerning view recognises the ambivalent nature of platforms. While platforms can introduce imbalances and governance complexities requiring vigilant regulation to ensure fair participation (Tiwana, 2014), they also present strategic benefits for all stakeholders. Platforms enable small and medium enterprises (SMEs) to engage with larger markets, gaining visibility and opportunities for growth by addressing niche demands. Apple Inc.'s platform strategy exemplifies how integration with a global network of developers can augment service offerings while supporting smaller contributors (Stratton, 2020).

Further, platforms centric SCs equipped with modern digital technologies and artificial intelligence substantially optimise design and production workflows, ensuring that supply dynamically matches demand. This enhancement not only streamlines production and inventory control but also equips the modular construction industry to swiftly adapt to changes in market dynamics and consumer preferences. Also, the analytics derived from interactions on these platforms provide invaluable insights into market trends and operational performance, enabling the refinement of products, reduction of waste, and improvement of customer satisfaction. This shift towards an analytics-driven, consumer-oriented approach signifies a notable advancement in the strategic market positioning of the modular construction sector (Kagermann, Helbig, Hellinger, & Wahlster, 2013).

Overall, the advent of platform thinking within the modular construction SC represents a significant departure from traditional methods, ushering in an era defined by enhanced integration, flexibility, and creative innovation. These platforms do more than just improve collaborative efforts and customisation capabilities; they transform the future of the industry, guiding it towards a path of increased agility, efficiency, and a stronger focus on customer needs.

Conclusion and Way Forward

The construction industry including modular, known for its historical resistance to change, finds itself on the brink of the impending platform revolution, an unstoppable force that has already reshaped various manufacturing and production industries. While acknowledging the industry's apprehensions and reluctance, it is also imperative for construction professionals to embrace this transformative wave. Accordingly, this study serves as a forewarning for construction professionals, encouraging them to embrace the imminent platform revolution. However, it is also crucial to dispel the notion that platform solution serves as a one-size-fits-all solution for the modular industry's challenges, a tendency often observed in past innovation breakthroughs. Instead, this study critically explores how platforms may reconfigure modular SCs, unveiling opportunities for effective horizontal and vertical integrations, demand responsiveness, and the ability to generate more value impacts through cross-functional collaborations. The envisioned platform transformation in the modular SC is nuanced, neither a purely positive nor negative scenario. While it promises an efficient, collaborative, and responsive SC, it concurrently poses threats of consolidating power among major industry players. While the primary objective of implementing a platform solution is to facilitate an effective industry-wide collaborative SC, the existing competitive dynamics within the market structure pose a substantial impediment to realising the identified prospects. Consequently, advocating for a transparent and equitable platform governance model is imperative to pre-empt potential adversities and ensure the success of the initiative. This governance model is anticipated to prevent exploitation of medium and small-scale market players by larger entities, fostering a mutually beneficial, win-win scenario. Moreover, acknowledging the perceived hindrance posed by data sharing, particularly within a competitive environment involving market competitors, necessitates the establishment of predetermined governance mechanisms. These mechanisms are instrumental in delineating how data is shared, with whom, and to what extent, thereby fostering a consensus among platform participants while addressing concerns related to the exposure of intellectual properties within the industry. Therefore, it is essential for the modular sector to prepare for the platform revolution, not only by understanding its potential benefits but also by being cognisant of the challenges it may pose. Prepared with this knowledge, construction professionals can realise preventive mechanisms, drawing insights from other sectors that have already navigated the complexities of the platform revolution. The call to action envisioned in this study is clear: engage, adapt, and lead the way forward for modular industry in this platform-induced transformative era.

ASSESSING THE ENVIRONMENTAL IMPACT OF THE CONSTRUCTION PHASE – A SIMULATION-BASED METHODOLOGY

Danh Toan Nguyen[1] and Walter Sharmak[2]

[1] University of Kassel, Kassel, Germany
[2] Technische Hochschule Mittelhessen - University of Applied Sciences, Giessen, Germany

Abstract

The construction industry makes a significant contribution to global resource and energy consumption and the associated CO2 emissions. The environmental impacts in the execution phase compared to the planning and operating phase have not yet been comprehensively investigated in research for several reasons. This paper presents a methodology for the preliminary calculation of greenhouse gas emissions on the construction site by simulating the nonlinear behavior of the complex and dynamic construction processes. The estimated results will help to optimize the execution planning of the construction processes from an environmental perspective.

Introduction

According to a report by the International Energy Agency, the construction and operating of buildings accounted for the largest share of both global final energy consumption (36%) and energy-related greenhouse gas (GHG) emissions (39%).

However, the Intergovernmental Panel on Climate Change (IPCC) predicted that the construction sector has the greatest potential for significant reductions in greenhouse gas emissions compared to other major manufacturing sectors (IPCC, 2014). Particularly during the operating phase, the building energy requirement will decrease due to the increased requirements for new buildings and renovations of old buildings. Due to this development, the embodied energy will become more important as its share of total energy has increased significantly, based on the calculated life cycle of 50 years. For this reason, studies into sustainable materials like clay are currently gaining great importance in research and development (Tourtelot et al., 2023; Muntari and Windapo, 2020).

Compared with the operating phase, the construction phase is a short-term phase and is believed to have small environmental impacts, so it has not attracted much research (Slossharek et al., 2021). However, to exploit the full potential for reducing greenhouse gas emissions in the construction industry, the execution phase should also be optimized in this regard.

Nonetheless, the complex and dynamic parameters and their relationships on the construction site make it difficult to quantify the environmental impacts in the execution phase. In current practice, only qualitative analyses are carried out to demonstrate the sustainability of the construction site.

The use of simulations can provide a cost-effective and efficient approach to analyzing construction processes and evaluating the resource consumption of different construction methods.

Several researchers have integrated simulation methods such as discrete event simulation (DES), system dynamics (SD) and agent-based simulation (ABS) for various purposes in construction (Xie and Peng, 2012; Xia and Sun, 2013; de Assis et al., 2021). However, such a simulation-based approach is rarely used in the environmental impact assessment of the construction phase.

In this paper, a hybrid simulation model combining ABS and SD is proposed to analyze the environmental performance during the construction phase.

Autonomous agents represent construction processes, and their needed resources can interact with each other according to predefined operating rules. SD provides causal effect loops to simulate the nonlinear behavior of dynamic construction processes. A simple example is presented as well to test the developed simulation model.

Work methodology

The simulation of the processes in the construction phase requires a variety of inputs from different areas for realistic results, such as data on the work schedule, quantities, the planned construction methods and the construction site facilities.

From an IT perspective, the different data structures of the required data represent a major challenge for the simulation. Another challenge is that the construction processes are nonlinear and therefore the traditional discrete event simulation may not lead to reasonable results.

For this purpose, hybrid modelling using multiple interacting agents and system dynamics is used for the simulation in the presented approach of this paper.

Agents are defined in ABS as intelligent autonomous objects that represent real parties without global control and unified goal (Ren and Anumba, 2003).

Autonomously acting agents interact directly with their predecessors and successors. According to predefined operating mechanisms, process agents register their required resources in a central board system that is used for all agent negotiations. Depending on the availability

of resource agents, the control centre processes all information in a specific protocol and initiates resource allocation accordingly. Both construction processes and needed resources are represented by agents.

System dynamics simulation is a top-down approach based on information feedback to analyse complex system behaviour between project elements within a predefined boundary (Ding et al., 2016; Ding et al., 2018). Typically, system dynamics models are structured by stock-flow diagrams, which describe the movement of entities from start to finish in a model, and by causal loop diagrams, which capture the chain influences of a cause that can be traced back to the original cause and a set of related variables.

The concept of causal loop diagrams is explained in the simple well-known example related to the human population (Figure 1).

If the human population increases (larger birth rate), this leads in loop 1 (left) to the population continuing to grow in the future. Such a loop is called a Reinforcement Loop (R). Since people need some time after birth before they are able to have children of their own, the loop has a delay, which is represented by two pipes in figure 1. This delay is not deterministic (e.g. 18 years), but depends on many cultural, economic, and other factors. For this reason, this delay should be represented using a suitable probability distribution. Deaths cause the population to decrease. This is shown in the loop on the right (Balancing Loop B). Loop B also has a delay because most people do not die immediately after birth. This delay also has to do with many factors, such as available medical care, exercise or eating habits and cannot be used as a deterministic value (e.g. 75 years), but in this case too a suitable probability distribution should be used.

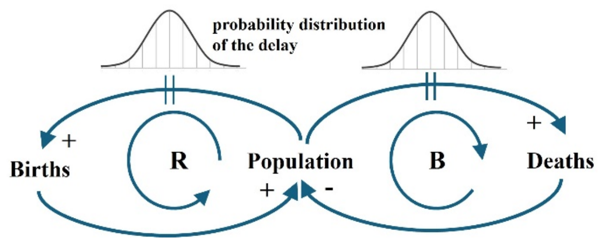

Figure 1: a general example of Causal Loop Diagrams

Another well-known example is related to using work overtime to accelerate the schedule (Figure 2).

Two feedback loops can help decision-makers become aware of both the positive and negative impacts of this management policy. In Figure 2, loop 1 is a reinforcement loop. Indeed, starting with an assumption that Overtime_hours grows and going around the loop counterclockwise (according to the direction of the links going from Overtime_hours through Fatigue, Completed_Work, Remaining_Work and come back to Overtime_hours), we get growth of Fatigue, but at the same time this leads to decrease of Completed_Work, increase of Remaining_Work and again get growth of Overtime_hours, so the same result as the initial assumption. Alternative check by counting the number of negative links: This loop has two negative links, so it is a reinforcing loop.

This reinforcing loop shows a negative impact of the overtime policy. On the other hand, loop 2 is a balancing loop, which indicates the positive effect of working overtime. The adoption of overtime means an increase in Overtime_hours. Let's go around the loop counterclockwise. The increase of Overtime_hours leads to an increase of Completed_Work, and that by-turn leads to a decrease of Remaining_Work. Consequently, the decreased Remaining_Work will result in the reduction of Overtime_hours, so the result contradicts the initial assumption. Alternative check by counting the number of negative links: This loop has one negative link, so it is a balancing loop.

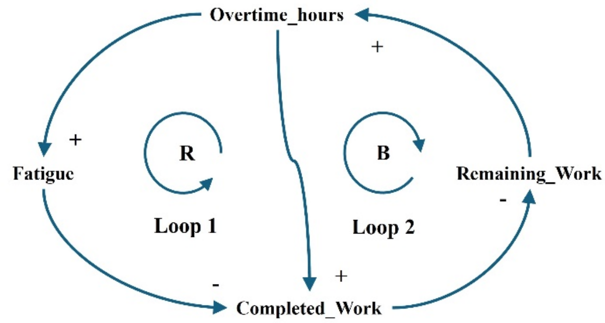

Figure 2: a general example of Causal Loop Diagrams using the Feedback processes related to overtime.

In the presented approach, SD including the schedule pressure loop and the rework loop, is embedded in the processes to capture the dynamic behaviour.

Process patterns are used to facilitate the use of the construction processes in the simulation. A relational database is developed to manage the data of the process patterns. Process patterns are generally used to describe repetitive processes in various construction projects (Dori, 2016; Nguyen, 2024). The process patterns can therefore be used when simulating various projects.

The process pattern structure includes the following elements (Figure 3):

- Description: depicts the process pattern and its application.
- Metadata: contains information about when the process pattern was created, who the author is and some tags to help find patterns.
- Object(s), one or more building object types are created by completing all steps as described in the process pattern, such like walls, columns etc.
- Operations: represent required steps of the process at the second level of granularity.
- Activities: represent required steps of the operation at the third level of granularity.

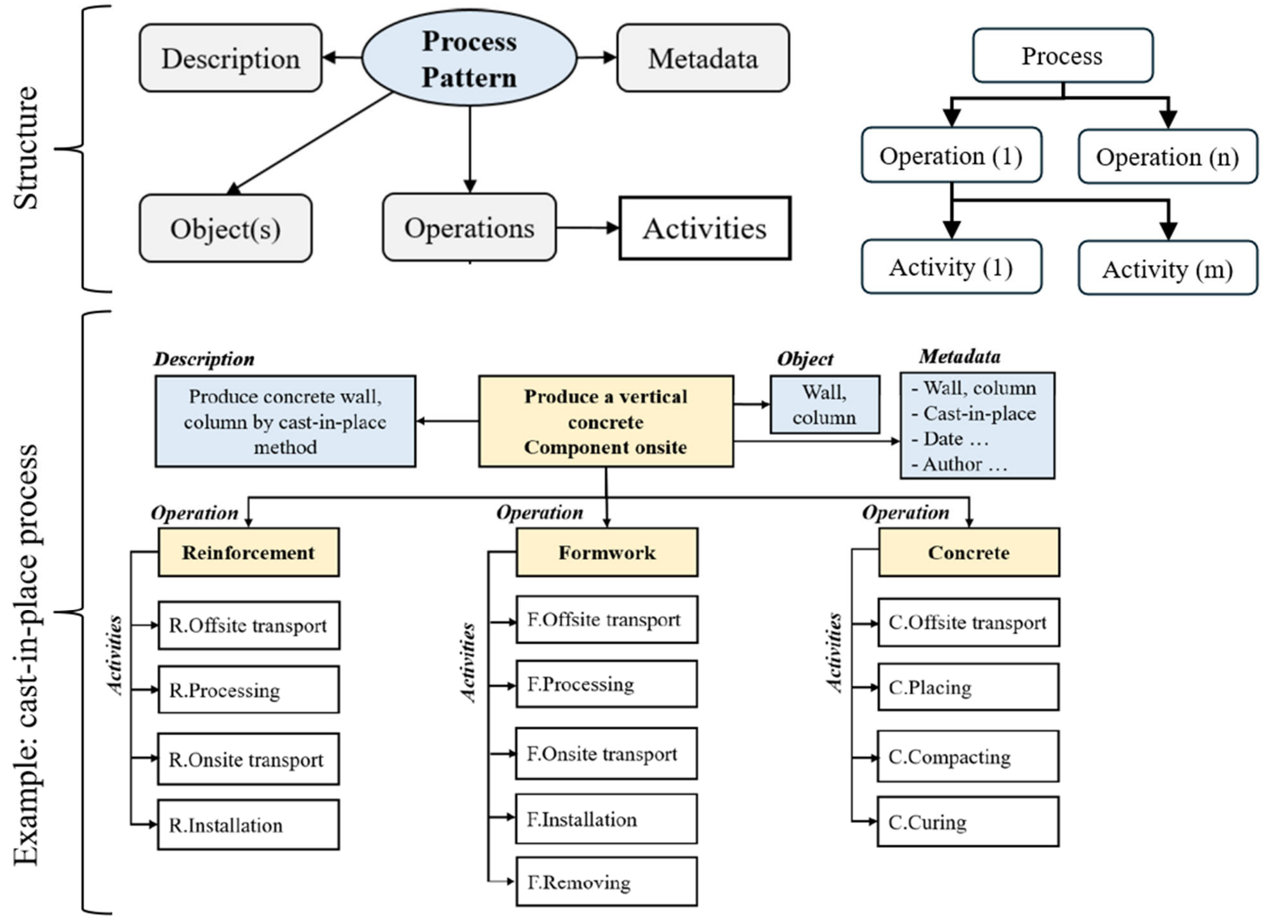

Figure 3: the structure of the process patterns with an example

The necessary information about the building components (such as classification, quantities and dependencies) is extracted from the Building Information Model (BIM). Information about processes and resources is captured by reference to appropriate process patterns. These sources of information are used when initializing agents and populating attributes. In a later step, the required LCA-datasets are queried from a suitable LCA database as a CSV file.

System Dynamics modules are created by combining stock-flow structures and effect-causal loops diagrams. Causal-effect loops are located within the operation agents and consists of reinforcing and balancing loops. A reasonable delay in each loop is considered in the simulation model and its value is represented as a probability distribution using practical experience or literature sources. Examples of the considered dynamic factors in SD Model include overtime and error-related rework. Figure 3 shows schematically the simulation framework planned in the presented methodology.

Figure 4 shows the Error Detection and Rework Loop built in the simulation Software Anylogic. Errors in construction tasks are often inevitable because of unreliable workflow in an uncertain environment (Alzraiee et al., 2015; SangHyun Lee, 2006). Errors lead to rework that consumes more resources than expected, so the environmental impact also increases significantly. However, errors and rework are often overlooked in previous studies on environmental impact assessment.

The rework cycle is affected by the workforce level, productivity, and quality of the performed work. While undiscovered errors are inherently unobservable, the final stages of a project tend to see a big increase in rework discovery. Indeed, crews are aware of their mistakes when the work comes near the end, so the time of error discovery depends on the completion rate. It is very much like finally putting the pieces of a puzzle together. At the end, it becomes quite obvious which pieces are missing or have the wrong shape.

The suggested rework cycle includes four typical loops that result from management policy. The first loop R1 shows the causal-effect relationship between schedule pressure and work with errors. High schedule pressure increases error rate and flawed work. Consequently, the remaining work or initial scope increases. This adversely impacts and increases the schedule pressure again. The second loop B1 shows that if the management policies increase the productivity rate, the work remaining will decrease. The arrow link with minus symbol connecting

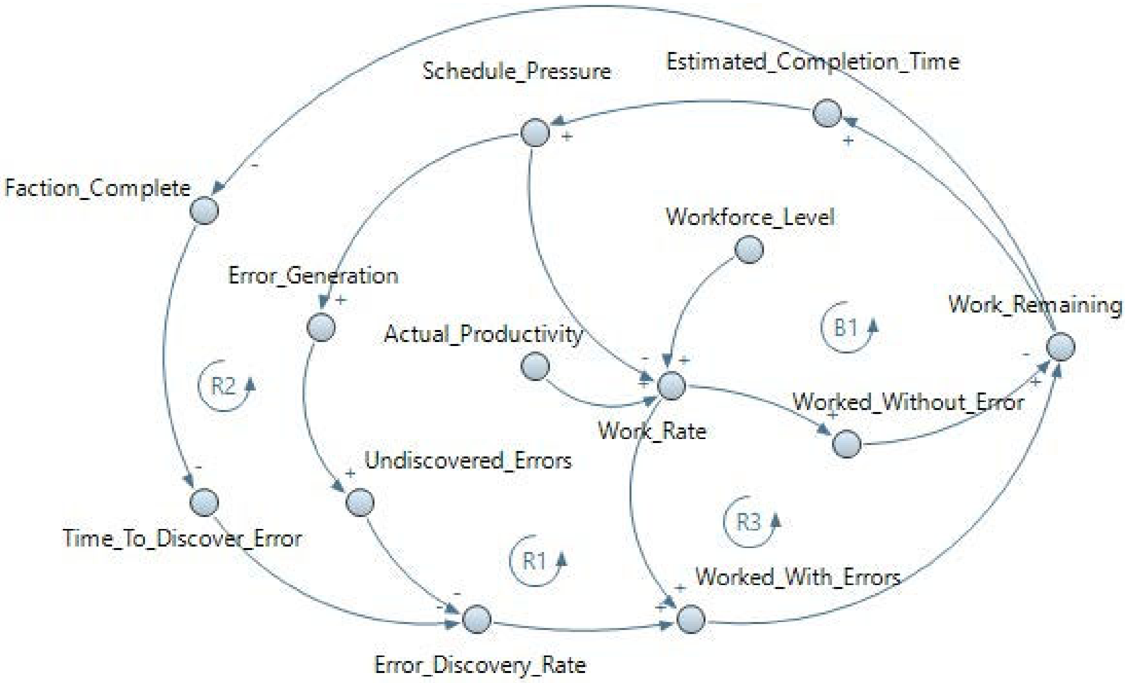

Figure 4: The implemented Error detection and rework feedback loops in AnyLogic.

node Worked_Without_Error and node Work_Remaining has negative polarity (minus symbol) indicating that if node Worked_Without_Error increases, node Work_Remaining decreases. The third loop R2 shows the fact that the errors are usually detected when the project nears completion. The fourth loop R3 indicates that the increase in work rate could increase the errors, and hence increase the work remaining and schedule pressure.

Case study

To test the applicability of the proposed hybrid simulation methodology for assessing the environmental impacts of the construction phase, a simple process scenario is introduced.

The described simulation environment is implemented in the AnyLogic software. Interfaces to various necessary data, such as the process patterns, are carried out through the SQL interface. Other data, such as LCA data sets or the construction quantities, are prepared in CSV format and imported into the AnyLogic environment.

In the case study, the construction phase of the shell structure of a virtual building is selected to apply the proposed methodology. The building has a reinforced concrete frame structure that is constructed using the in-situ concrete method.

The project delivery method is design-bid-build. The planners select the primary building materials in advance, while the construction companies select the auxiliary materials based on their construction method.

Construction companies and their contractors are responsible for transporting materials to the construction site and carrying out construction work on site. Construction works cause environmental impacts through the use of equipment and vehicles, consumption and waste of materials.

The range of environmental sources of influence lies within the decision-making area of construction companies, for example when selecting vehicles, equipment, machines and building materials during the construction phase.

Therefore, the scope of simulation in this case study includes the associated material supply chains and on-site construction operations.

All necessary data on resource consumption and greenhouse gas emissions are obtained from available construction standards and open LCA datasets or international studies.

According to the simulation framework shown in Figure 5, the simulation model is designed in three steps. First, the construction phase of the building is decomposed into units, including product units and process units. Secondly, product units and process units are analyzed to select corresponding process patterns. Third, agents are established and enriched by embedding SD models.

In this case, the building consists of two product units. These are vertical elements such as columns and walls and horizontal elements such as floors and beams.

Process entities represent the cast-in-place concrete method, which is applied to produce product entities of the building shell structure. There are two process entities to produce vertical and horizontal product entities. Each process entity includes three main construction operations: reinforcement, formwork, and concrete. Each operation contains several activities which utilize different resources. An operation can be carried out by

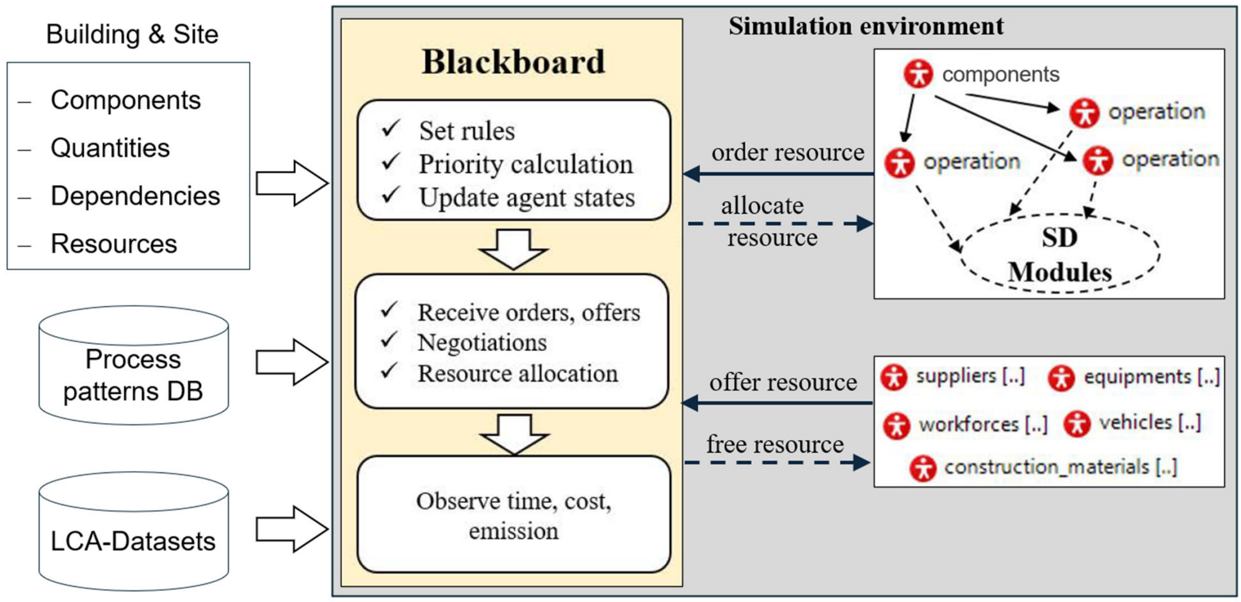

Figure 5: Schematic representation of the planned methodology

different methods. For example, several formwork options can be used to produce one type of concrete structure. When it comes to reinforcement work, reinforcing bars can be processed in the factory or on construction sites.

Depending on the variants selected, modelers can query the process pattern database to identify the specific activities of each process. In addition, the corresponding resources of these activities are determined based on the process pattern.

The abstracted simulation elements of the construction phase are shown in Table 1. For example, building components are defined as product units. Construction-related equipment and building materials that have a direct or indirect impact on the environment are defined as renewable or non-renewable resources.

Table 1: Included Concepts in the simulation model.

Real world	Simulated world
Building components	Product agents
Construction operations	Operation agents
Construction material	Resource agents (non-renewable)
Equipment, workforce	Resource agents (renewable)
Causal-effect relations	Causal-effect loops

Using the proposed simulation model, four scenarios are analyzed to quantify the impact of implemented methods on the environmental performance of the construction phase. The scenarios take into account push or pull controlled processes as well as different resources for the planned construction.

The greenhouse gas emissions (expressed as carbon dioxide equivalents CO2eq) of the four scenarios using the simulation are shown in Table 2. By applying pull-driven processes, scenarios two and four can significantly reduce emissions compared to scenarios one and three.

Using the ABS simulation without the SD models shows lower greenhouse gas emissions results than the ABS-SD simulation. Understandably, the ABS-SD model assumes that error and rework lead to a higher material consumption, so the greenhouse gas value should be higher than the ABS model results. In addition, the ABS-SD model takes into account overtime during night shifts, requiring vehicles, machines and crews to work in uncomfortable conditions, resulting in longer working hours and higher energy consumption.

The SD components take schedule pressure loops and rework loops into account in the construction processes. These loops are needed to capture the realistic behaviour of the construction processes. By effectively applying lean methods to reduce waste in the processes, the effect of these loops will be reduced, and the results of the hybrid ABS-SD simulation will, in the best case, be identical to those of the ABS simulation.

Notably, material consumption contributed the highest CO2 equivalent (61%-64%) among all construction phase impact resources. This result is consistent with results from previous studies that found that materials account for approximately 60–80% of the CO2eq ratio depending on the construction type (Feng et al., 2018; Y. Wang et al., 2017).

Table 2:Simulation results for one typical story.

Scenario	CO2-eq (kg) ABS-SD	CO2-eq (kg) ABS
1	34.809	29.239
2	31.055	29.107
3	33.633	28.124
4	29.589	27.978

Conclusions

The proposed methodology in this paper helps to assess the environmental impact of the construction site and contributes to improve the processes on future construction sites from an environmental perspective. It does not consider only the technical aspect such as the choice of the construction method but also the dynamic changes to the processes. Direct performance measurement on the construction site seems to be difficult because it requires precise documentation of many factors in real-time, which needs a lot of effort and is not justifiable for the construction companies. This makes the target-performance comparison almost impossible. In any case, the proposed simulation-based methodology in the execution planning phase offers a pragmatic solution in this context.

Future development efforts are needed regarding the definition of new patterns for different construction processes and the developing of simulation templates to simplify future use.

The method can also be extended to consider not only the environmental aspect, but also economic and social aspects, which are essential components of sustainable construction.

FIRE SAFETY DESIGN OF BUILDINGS: A DECISION SUPPORT FRAMEWORK TO ASSESS THE SAFETY OF OCCUPANTS

Alessandro Carbonari, Massimo Lemma, Martina Tarsi
Polytechnic University of Marche, Department of Civil and Building Engineering and Architecture
60131, Ancona, Italy

Abstract

At the design phase, designers must investigate what design solution represents the best trade-off among a set of simulated fire scenarios. This choice requires a quantitative assessment, embracing the concept of performance-based design. This task can be facilitated using key performance indicators (KPIs). A KPI assessing life safety in the event of a fire is tested in this paper. Also, a framework to facilitate the mapping of KPI values through a graphical visualisation superimposed on the BIM model will be showcased. As a results, the life safety performance assessment is performed at any points of the building layout.

Introduction

The process of fire safety design of buildings entails the assessment of a variety of fire scenarios chosen among the most severe events that could reasonably occur. Out of all the solutions assessed in the various fire scenarios, that one which represents the best trade-off for the specific case will be selected. To this purpose, the adoption of quantitative assessment of the effects of fire on life safety related to the assumed design solutions would help make a grounded, non-personal decision. Quantitative assessment is permissible within the performance-based approach. This paper adopts this approach and tries to go even beyond the current concept of this method, which usually assumes that one scenario at a time is evaluated. Indeed, individual design solutions are evaluated in terms of whether or not they exceed performance thresholds, i.e., the quantitative translation of fire safety objectives. Whereas the approach proposed in this paper wishes to supply the designer with a quick and easy to handle method for choosing the best design solution for the specific case under scrutiny. The safety for occupants will be assessed at every point in the building. To this purpose, the building plan was discretized by creating a square mesh grid. This approach facilitates the comparison among alternative design solutions by making a spatial evaluation of life safety performances in case of fire. In order to make this process effective, one or more KPIs could be identified, not only to check whether a solution meets required design specifications, but also provides feedback about the tested design solution.

Therefore, the aim of this paper is to develop a framework, compatible with a BIM environment, capable of implementing performance-based procedures to assess the degree to which fire safety objectives are being met, in terms of life safety of occupants, through the use of a KPI. The KPI, in addition to assessing any design solutions, must supply a clear and immediate representation of safety conditions levels for occupants. Technically, a graphical display of the KPI has been worked out, taking advantage of the BIM-based design environment. Thanks to the approach proposed in this paper, not only do we display the results of simulations in the BIM environment, rather ASET and RSET values are combined and processed to check the positions where the KPI fails to be verified. It suggests what areas in a building are critical and what countermeasures can be adopted to improve life safety in the event of a fire. This approach enables a building-wide assessment and allows designers to compare an increasing number of design solutions until reaching a decision about the best one for the type of building under consideration. An analysis of the overall framework and workflow is performed to leverage the BIM environment as the preferred collaborative environment.

Literature review

Fire engineering has undergone significant innovations in the latest years, even introducing performance-based approaches. These approaches have proven particularly effective for those scenarios where traditional prescriptive design techniques are not sensibly applicable. Specifically in complex buildings and in buildings that combine different uses, fire safety engineering (FSE) may be the only practical way to achieve a satisfactory standard of fire safety (Fire Protection Association, 2008). Fire engineering has played a pivotal role in liberating building design, allowing for greater architectural flexibility while maintaining high levels of safety (Wilkinson et al., 2013). The safety of occupants in case of fire in buildings is one of the most crucial aspects of FSE (Kong et al., 2013). This is complex due to the high complexity of fire dynamics and the variability of human behaviour. As reported in the Italian fire regulation (D.M. 03/08/2015, 2015), the criteria underlying the performance-based approach for assessing life safety is ASET > RSET, that is occupants can feel safe if the time available to a safe escape (ASET) is greater than the time required to a safe escape (RSET). The difference between the two values is called 'safety margin'. However, this concept has never evolved over time and has not adapted to developments in numerical evaluations (Schröder et al., 2020). Thus, mainly macroscopic assessments have been provided, evaluating only selected points in the building, and lacking a comprehensive view of the safety of occupants. Some methods for a more specific assessment have been proposed. For example, a system proposes expressing tenability conditions and egress accessibility of areas of the building (Poon, 2014). This introduces the concept of available safe utility time (ASUT) that must be longer than the required safe utility time (RSUT), where ASUT represents the time whereby an area is safe to use and RSUT indicates the time for the last person to safely use the area for egress. Another approach evaluates the safety level of egress routes and compartments (Mirahadi et al., 2019). It showed blocked routes, determined the safest egress route from each compartment, and identified critical fire initiation locations. In addition, for an even increasing number of details, a visual representation to depict safety conditions across the entire space was introduced (Schröder et al., 2020). Contrary to earlier evaluations focused on particular areas, this methodology measured safety thresholds comprehensively. Consequently, they produced maps concerning ASET and RSET, and the difference map was derived by subtracting RSET from ASET, effectively displaying the safety margin in the illustrative case of one room. The process of establishing ASET and RSET at each discrete point on the maps aim to move beyond macroscopic representation in favour of a dynamic approach supported by advanced simulation models.

Another critical aspect in the application of FSE concerns the definition of fire scenarios and the choice of design fire scenarios for building structures (Del Prete et al., 2016). The number of possible fire scenarios is typically huge and can hardly be analysed singularly. Therefore, it becomes critical that those design fire scenarios that best represent the most severe cases for the structure are chosen. The US fire regulations NFPA 101 (National Fire Protection Association, 2017) provide us with eight predefined starting design fire scenarios on which to set specific scenarios for different activities. Scenarios selected as design fire scenarios should include but not be limited to those eight predefined. However, they are an excellent starting point on which to develop multiple scenarios for the specific activities.

The performance approach can be facilitated by BIM's ability to generate and return structured information. Fire safety engineers have been slower to adopt BIM as compared to other disciplines (Malagnino et al., 2022). Several research focus on the integration of BIM and fire prevention simulation tools (Wang et al., 2015; Sun and Turkan, 2020). The great limitation of one-way exchange between BIM and FSE tools was also identified. An example to overcome this limitation concerns the development of an open-source framework called 'Evac4BIM' to facilitate two-way data exchange, with a specific focus on fire evacuation (Yakhou et al., 2023). The authors yield the results of numerical evaluations available in the BIM environment which become accessible to all stakeholders but no graphical representation of the results covering every point of the building was provided in return.

Research questions

This paper suggests a methodology and develops tools to answer the following research questions (RQs):

1. can a BIM-based framework assessing fire safety performances of buildings, in terms of life safety for occupants, be defined and implemented to support the designer during the design phase?
2. can a KPI be defined to assess the safety conditions of occupants and to gives back a clear and immediate visualization in a BIM environment?

Materials and methods

In order to answer the research questions formulated in the previous section, a framework to support the designer's choices during the assessments of life safety in case of fire emergencies was developed. This evaluation was meant to overcome the current approach based on calculating ASET and RSET only at a limited number of locations in a building and working out results that do not represent the consequences of the fire on occupants. Indeed, the current numerical evaluations can tell us whether occupants were able to exit the building or were entrapped, but it does not tell us where in the building they may have been hampered by the effects of fire. Thanks to the approach proposed in this paper, we want to assess the safety of the occupants at all points of the building, discretizing the entire area using a grid. In this way, it will be possible to visualise the points where the occupants may be subject to the effects of fire and the areas that are most dangerous for every different design scenario.

The project workflow for each design fire scenario

A representation of the processes that could be carried out to handle each design fire scenario is depicted in Figure 1.

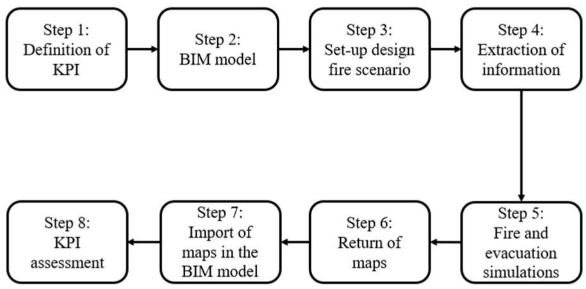

Figure 1 - Conceptual representation of the flow to handle design fire scenarios

By applying all the steps to the design fire scenarios identified, it will be possible to compare the different design solutions and decide which represent the best trade-off. According to the performance-based approach, KPI must be identified as a first step (step no. 1). Having set life safety as the aim of our work and taking the Italian fire regulations (D.M. 03/08/2015) as a reference, the safety margin (t_{safety}), i.e., the difference between ASET and RSET, was chosen as the KPI. As reported in paragraph M.3.2.2 of the reference regulation (D.M.

03/08/2015), this safety margin can either be set as a percentage value, e.g., RSET must double ASET, or as a predefined time limit. The minimum required threshold in the fire regulation is 30 seconds (Eq. 1), which is the threshold set in the test case reported in this paper. Hence, the KPI was set as:

$$t_{safety} > 30\ seconds \quad (1)$$

The BIM model of the building must be available (step no. 2). In the application proposed in this paper it was created within the authoring software Revit™. Once the design solution has been assumed for the design fire scenario under consideration (step no. 3) the required information is extracted from the BIM model (step no. 4). The latter will be needed as input to simulation tools (step no. 5). Two different simulation software tools were used for this step. The execution of fire simulations was entrusted to the software FDS (fire dynamics simulator). It is a field model, i.e., it divides the environment into elementary volumes, calculating and outputting data for interested variables in each volume. In the input list for FDS, in addition to geometry and fireplace, even the positions and quantities of the slices are specified as output, because they are necessary for the graphical visualisation of results. The use of this software becomes relevant to our method, as long as the building's space must be discretized to assess the safety of the occupants at every location. Then, the Jülich Pedestrian Simulator (JuPedSim) was used to conduct evacuation simulations. It represents an extensible framework designed for the simulation and analysis of pedestrian movement at the microscopic level (Kemloh Wagoum et al., 2015). Again, the simulation environment was discretized to assess the passage of occupants across every cell of the grid. In order to read the results of the simulations clearly and immediately, three Python scripts have been implemented to obtain a visual representation of them (step no. 6). In practice, maps will be produced containing the ASET and RSET evaluated at each point of the building and, as a result, the safety margin map, i.e., the aforementioned KPI, can be obtained. The maps created are imported into the BIM model of the building to visualise directly within it (step no. 7). At this point, the KPI must be evaluated by the designer (step no. 8). If the KPI is verified and, therefore, the threshold is not exceeded, the proposed solution can be considered and compared with other ones. Otherwise, the designer is required to investigate other solutions on the considered design fire scenario. In this way, the designer can assess the effect of different design solutions on a design fire scenario quantitatively and efficiently.

Extraction of information

Structured information needed to carry out evaluations can be extracted from the BIM model of the building. In particular, it is possible to automatically create the input list for the simulation software tools. Having implemented the building model in Revit™, Dynamo™ was chosen as the tool for data export. In addition, Dynamo™ was used to read the geometry of a building, to create a mesh of the building area composed of quadrilateral finite elements characterized by a predefined parametric value, and to export the list of mesh points along with their coordinates automatically. In the case study reported in this paper, a mesh element size, to create the maps, as big as 0.50 x 0.50 m was used. This size of the mesh was considered accurate enough to represent the path followed by people and the spread of fire. The authors' opinion is that a smaller mesh size would not add relevant information about hazardous areas in the building.

Return of maps

In order to provide a clear and immediate visualisation of the results of the occupants' life safety assessment, maps have been implemented. For this, we have taken into consideration what was proposed by Schröder et al., 2020. The authors proposed using the Python programming language to create ASET, RSET and difference maps by importing the results of fire and evacuation simulations into scripts. The Python scripts implemented in our paper are an adaptation of those ones made available by Schröder et al., 2020.
ASET maps were worked out for two environmental parameters: the temperature room and the light extinction coefficient. The thresholds for these parameters are 45°C for the temperature field and 0.23 m^{-1} for the light extinction coefficient field, assessed at the height of 2 metres above the floor level (Zehfuβ, 2020). The script to obtain the ASET map converts the slices given as output by the FDS simulation as an ASCII file. The geometry of a building, the mesh size, and the colour scale of the maps are the other input data needed. The resulting ASET map is produced in both 'png' and 'txt' formats. RSET maps were worked out according to the trajectories of the occupants. In our case, ten different trajectories for each hypothesised design solution were assumed for the occupants, arranging them randomly. The script to realise the RSET map is divided into two parts. The first part processes the results of the imported occupant trajectories. These are contained within an 'xml' format file processed from the 'txt' format file provided by the evacuation simulator. The second part of the script creates the global RSET map, interpolating the worst cases from all the earlier ones. The input set consists of the building geometry, the mesh size, and the map colour scale. The output is the RSET map in 'png' and 'txt' formats. Once the final ASET and RSET maps were created, the difference map was completed. The script creates the difference map, which is the map including safety margin values, by subtracting the RSET map from the ASET map. It accepts ASET and RSET maps in 'txt' format as inputs, as well as building geometry, mesh size, colour scale of the map and produces the difference map in 'png' and 'txt' formats.

Import of maps into the BIM environment

Once the maps have been created via Python, these were imported into the BIM environment to be assessed by the designer. To conduct this step, a flow was created in Dynamo™ that imports the text file produced by Python, containing the KPI values. In the BIM model, the discretization mesh was already created, as shown in the section 'Extraction of information'. A geometric element was placed in the centre of each mesh element. Then, a new design parameter was created, named 'T_{safety}' and associated with the above element. The text file created by Python was converted into Excel and imported into the Dynamo™ flow. Next, Dynamo™ nodes were used to transform the excel matrix into a list, so that it could be imported as a list node. The values contained within it were assigned to the 'T_{safety}' parameter according to the order of the list of elements. At this point, each element was assigned a different colour according to the value of the parameter. Values below 30 seconds, i.e., the KPI threshold (Eq. 1), were coloured red, the others green. Some points are left without a numeric value. These have been colored white and they indicate that no occupant has ever walked through that point.

Application on a case study

The feasibility of the proposed framework was assessed through the case of a pilot building. It is a building located in the campus of the Polytechnic University of Marche (Ancona, Italy), which hosts the school of Medicine (Figure 2). It is an 8-floor level building, 7 floors above ground and 1 basement. The building is used for teaching, research, a library, and other services. For the purposes of this paper, only the ground floor of the building has been considered.

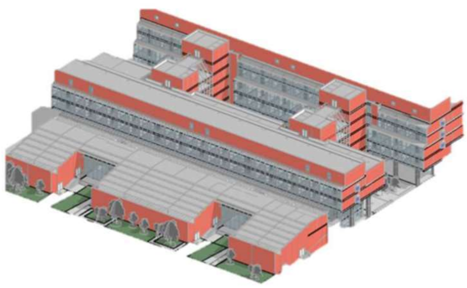

Figure 2 - 3D model of the pilot building

Fire and evacuation scenarios

Fire scenarios represent the most severe but realistic events that can occur while performing activities allowed in the building. These can be very numerous, especially in complex buildings. For the purpose of this paper, the default scenarios contained in the US fire regulations were considered. In fact, NFPA 101 covers a wide range of situations and defines fire scenario in Chapter 5.5.3. The latter provides us with eight starting scenarios on which to develop the most appropriate scenarios based on the specific case. In particular, two out of the eight predefined scenarios listed in NFPA 101 were analysed, namely:

- scenario no. 2, which describes a fire that develops through the burning of a material having an ultrafast growth curve, located along any major egress route. The interior doors at the beginning of the fire are supposed to be open. This scenario must address the simulation of the fire paying particular concern to people's egress problems. In fact, due to the hypothetical fire having a rapid spread, special attention should be paid to reducing the number of available egress routes, evaluating the availability and effectiveness of alternative egress systems and the consequences of the fire on the assets;
- scenario no. 6, involves an intense fire as a consequence of the highest possible fire load in normal operations in the building. It refers to the rapid growth in the presence of people.

In fact, designers are expected to test and compare several fire scenarios. They usually assume a first design solution and investigate the obtained performances. Then, changes could be made to the first solution to improve it and new investigations are performed until the verification process is concluded. In this paper, two scenarios have been assumed as relevant, each split into three subsets.

Referring to the scenario no. 2 of the NFPA 101 described above, the fire hearth was positioned along the corridor as this is the main escape route. The corridor serves offices, the library, the cafeteria and seven classrooms for a total capacity of 1040 occupants. The occupants inside the seven classrooms have also emergency exits directly into the classrooms. This set of scenarios is called 'scenario LS1'. Taking into consideration the scenario no. 3 of the NFPA 101, the fireplace was positioned inside the library. This set of scenarios is called 'scenario LS2'. In Figure 3 the fire compartment and the library are marked in green and blue, respectively. Each fire scenario was combined with ten different occupant evacuation trajectories.

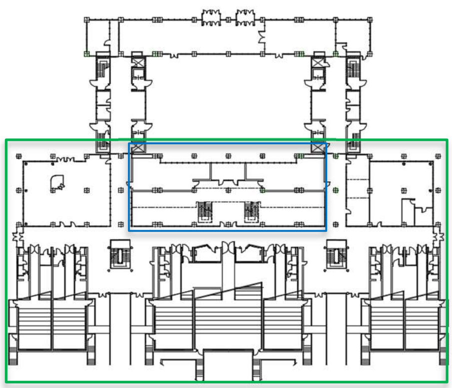

Figure 3 - Ground floor of the pilot building

Scenario LS1

For this first scenario, three alternatives were analysed. In the first case, called 'LS1_1 scenario', two emergency exits were placed along the corridor for the safe exit of the occupants. From the fire simulation, the values of the environmental parameters specified in the input list are obtained. In addition, it is possible to display them graphically with the set slices. An example is provided in Figure 4, displaying a slice taken from the FDS tool called

'Smokeview', concerning the light extinction coefficient reached at the end of the simulation (300 seconds) for the 'LS1_1 scenario'.

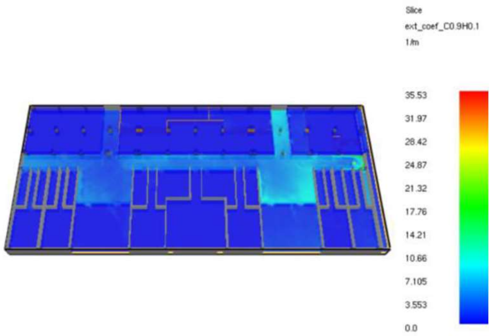

Figure 4 - Slices generated by FDS about light extinction coefficient for the 'LS1_1 scenario'

Regarding the evacuation simulation, the times required by the occupants are shown in Table 1 for the ten different trajectories (denoted by the term 'Seed_ID' from the number 1254 to 1263). In the second alternative ('LS1_2 scenario'), two emergency exits were added along the corridor. The effects of the fire remain the same as in the 'LS1_1 scenario', while the times required by the occupants change and are shown in Table 1. In the last alternative 'LS1_3 scenario', two more doors were added along the corridor for a total of six emergency exits. Again, only the RSET values change (Table 1).

Table 1 - Required safe escape time as a result of the JuPedSim simulation

	Required safe escape time [s]					
Seed_ID	LS1_1	LS1_2	LS1_3	LS2_1	LS2_2	LS2_3
1254	67.88	67.13	67.13	67.13	65.50	65.50
1255	67.63	66.50	66.50	66.50	66.62	66.62

Scenario LS2

In the 'LS2 scenario', the fire was placed inside the library, where the greatest fire load is expected. A first analysis assumed 38 occupants inside the library, which is divided into a reading room and the book depository ('LS2_1 scenario'). Also in this case, ten different simulations were conducted for the trajectories of the occupants and the times are shown in Table 1. Subsequently, an increase in the number of occupants, from 38 to 88, within the library and the elimination of subdivisions was assumed. This scenario was called 'LS2_2'. In this case, the fire simulation was run again because the building layout was changed and, as a result, the fire will spread differently. The third alternative ('LS2_3 scenario') differs from 'scenario LS2_2' only in that a library wall is replaced by a glass wall. The RSET values are contained in Table 1, but they are the same as in the 'LS2_2 scenario', while the fire simulation is re-run.

Maps generation

Once the simulations for the fire and evacuation have been carried out, the results are imported into the scripts developed with Python. The latter gives as output the graphical representations of the results in the form of a map. In particular, the values of ASET, RSET and the differences between the two are calculated. In this way, we can get a graphical representation of the safety margin, i.e., our KPI.

Scenario LS1

The ASET maps obtained for temperature and light extinction coefficient are shown in Figure 5-a and Figure 5-b, respectively. Two maps are shown because there are two environmental parameters to be assessed. The final ASET map is the one with the highest risk, i.e., with the least available time. The RSET map, on the other hand, can be seen in Figure 5-c. Finally, Figure 5-d shows the difference map obtained by subtracting RSET values from ASET values. In this map, therefore, the KPI is shown. When the value falls below the threshold of 30 seconds (Eq. 1) indicates that the point is not safe for the occupants. For the second and the third alternative of the 'LS1 scenario', since the position of the fire hearth and the layout of the building remain unchanged, the maps of ASET will be the same as those already shown in Figure 5-a and Figure 5-b. The new RSET maps have been produced and, as a result, difference maps were shown in Figure 6-a for the 'LS1_2 scenario' and Figure 6-b for the 'LS1_3 scenario'.

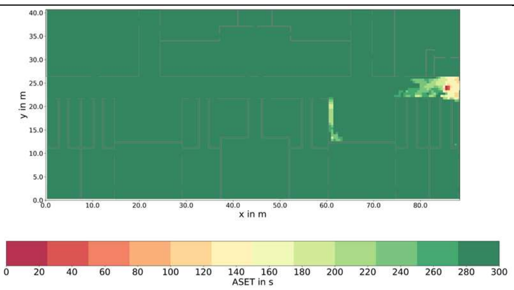
Scenario LS2

For the 'LS2 scenario', the difference maps are shown directly in Figure 7-a (scenario LS2_1), Figure 7-b (scenario LS2_2) and Figure 7-c (scenario LS2_3).

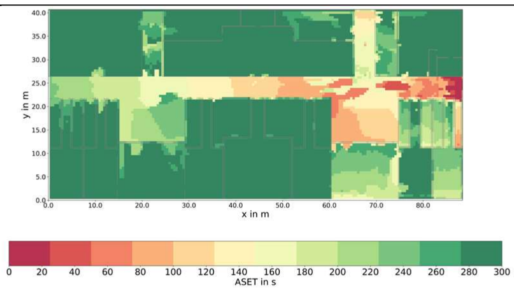
Visualization of maps in a BIM environment

Once the maps have been created via Python, these were imported into the BIM environment for a seamless evaluation by designers. To conduct this process, the Dynamo™ script created as described in 'Import of maps into the BIM environment' section was used. In this way, the designer can visualise the results directly within the BIM model and all stakeholders can collaborate in one environment. Even those who are not familiar with fire simulation tools can visualise simulation results in the BIM environment. For the sake of clarity, the Revit™ screenshots including the imported difference maps were shown in the following. For representative purposes, only the maps imported into Revit™ relating to the 'LS1_1 scenario' in Figure 8-a, 'LS1_2 scenario' in Figure 8-b and 'LS1_3 scenario' in Figure 8-c have been shown.

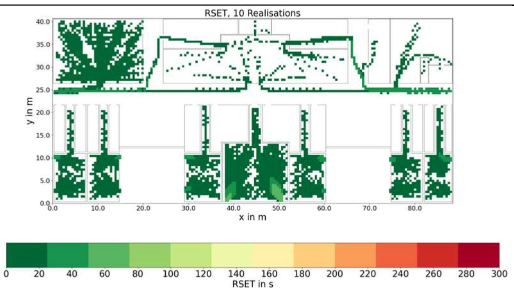
(a)



(b)



(c)



(d)

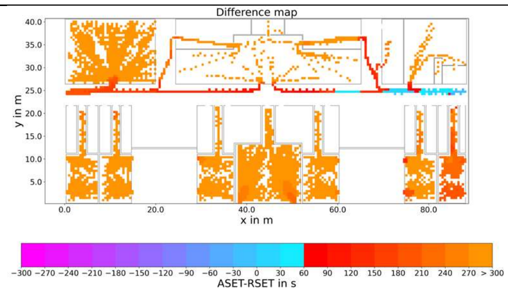


Figure 5 - ASET, RSET and difference maps for the 'LS1_1 scenario' (output of Python)

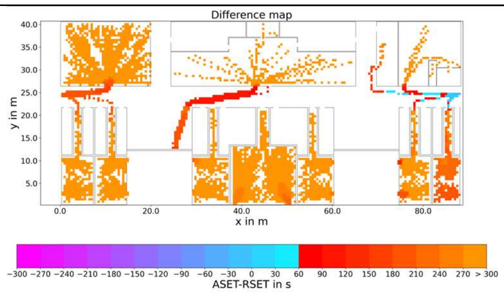
(a)



(b)

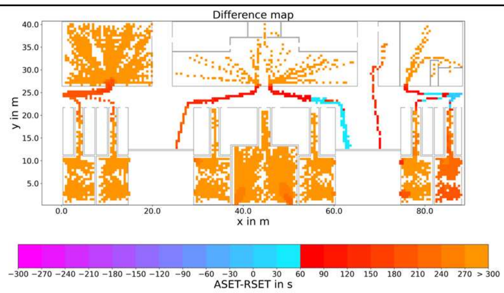


Figure 6 - Difference maps for the 'LS1_2 scenario' and 'LS1_3 scenario' (output of Python)

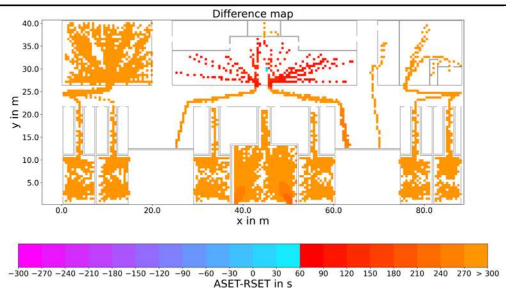
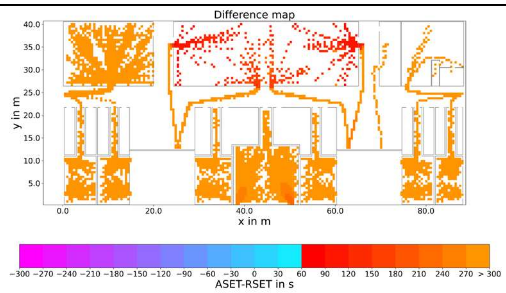
(a)



(b)



(c)

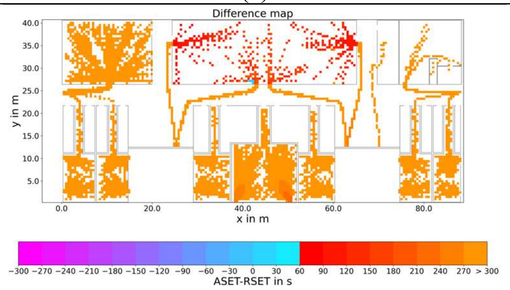


Figure 7 - Difference maps for the 'LS2 scenario' (output of Python)

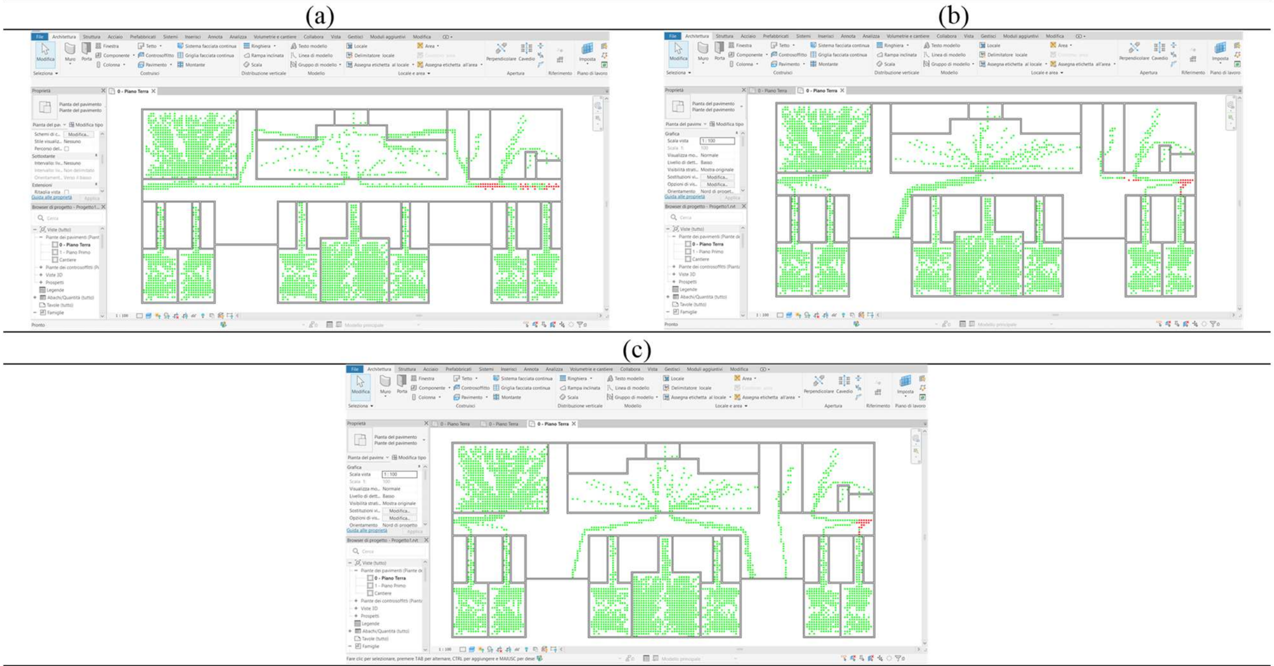

Figure 8 - Difference map for the fire compartment for the 'LS1_scenario' once it has been imported into Revit^{TM}

The pictures show the geometric elements inserted in the centre of each grid mesh. These take on a green colour when the value of the imported KPI associated with the 'T_{safety}' parameter is greater than 30 seconds. The red colour corresponds to a KPI of less than 30 seconds. When no value is associated with the parameter, it means that no occupant has passed through that grid mesh, so there is no RSET value and, so, no safety margin can be calculated. For this reason, these points have been left white.

As a result, Revit^{TM} was able to integrate the KPI information and display the points where safety conditions could not be verified.

Discussion

Thanks to the results reported in the earlier section, it can be seen that the methodology introduced gives us a clear and immediate view of the KPI values and, therefore, of the level of safety of the occupants inside the building in case of fire. Concerning the 'LS1 scenario', two emergency exits are not sufficient for a safe escape of the occupants. Indeed, in Figure 8-a includes forty-six points are coloured in red along the corridor. This means that the KPI threshold has been exceeded at those points and the occupants passing through that area are not safe. Consequently, the designer could think of adding two emergency exits along that corridor. The result is depicted in Figure 8-b and shows that conditions have been improved, despite twenty-three points close to the fire hearth still remained below the required safety level. To overcome this problem, the designer could choose to add two additional emergency exits, for a total of six. Figure 8-c shows that the life safety level has increased further, even if some but smaller areas are still unsafe, due to the position of the exits close to the fire hearth, and eighteen points are still red-coloured. This gives a hint to the designer about the number of emergency exits required and their location for a safe escape of the occupants. Comparing Figures 5-d, 6-a, and 6-b with Figures 8-a, 8-b, and 8-c, respectively, we can see the correspondence between the maps obtained through Python and the representation obtained once the maps are imported into the BIM model.

In the 'LS2 scenario', on the other hand, the maps obtained with Python show that the safety conditions are maintained even when increasing from 38 occupants inside the library (Figure 7-a), where only one point is unsafe, to 88 occupants (Figure 7-b), while leaving the number of exits unchanged. In the third hypothesis (Figure 7-c) where a glass wall is inserted, four unsafe points are seen close to the fire hearth, but there is no glass breakage due to the thermal action of the fire. This shows the designer that the fire that occurs inside the library does not spread rapidly along the escape routes. In the same way as the 'LS1 scenario', the maps imported into the BIM model were also obtained for the 'LS2 scenario'.

Thanks to the visualisation of the maps directly in the BIM model, a single working environment is created where even non-experts in fire simulation software can visualise the results clearly and immediately. In addition, the designer can compare different design solutions for each design fire scenario based on quantitative results (KPI values) that refer to the entire building. Thus, the safety of the occupants is assessed at every point, visualising the points and areas with critical conditions for them. The latter occurs when the KPI threshold is exceeded, that is in case the consequences of combustion result in environmental conditions that reduce the time available for occupants to get to a safe place.

Conclusions

In this paper, an approach has been proposed for assessing occupant safety in case of fire during the building design phase. This approach aims to go beyond the current concept of ASET/RSET evaluated only at specific points. Furthermore, current assessments do not supply insights into the zones or points where conditions become critical for occupants but instead offer a global evaluation of the safety of evacuation routes. The graphical visualisation of the KPI, in the form of maps, enables designers to immediately pinpoint those locations in the building that are critical for the occupants. This assessment was carried out by spatially discretizing the entire building, thus considering every point in the layout. Furthermore, thanks to the visualisation approach, the designer can quantitatively assess the assumed design solutions over numerous design fire scenarios. The KPI initially chosen to monitor fire safety objectives was mapped inside a BIM environment, importing maps created through Python. The KPI enriches the design model, and the entire method provides support to the designer when looking for the best trade-off, which is meant to implement the approach of performance-based design. In this way, the designer's decisions can be made quickly in a complex environment and a single collaboration environment can be created by importing the results of fire assessments directly into the BIM environment. One possible recommendation for future research involves identifying additional KPIs related to the other domains of FSE, such as structural safety. Another interesting aspect would be to implement the whole procedure within an open software and computing environment.

IFC-BASED COST ESTIMATION: APPLICATION TO A STRUCTURAL MODEL

Jacopo Cassandro, Claudio Mirarchi, Alberto Pavan
Polytechnic of Milan, Milan, IT

Abstract

Accurate cost estimation is an essential factor in the success of any construction project. Based on previous work, this study aims to use the IFC data model to support cost estimation processes and reduce human error. Through a code, developed in IfcOpenShell, a cost estimation has been made in IFC associating the new *IfcCostItems* with the IFC 3D model objects. The study was validated by applying the methodology to a real case of a structural model and defining a cost schedule for the structural project. Ultimately, this study seeks to support, verify, and improve public tenders quality of cost estimates.

Introduction

Accurate cost estimation is a crucial factor for any construction project's success. In the Architecture, Engineering, and Construction (AEC) industry, this task demands a high degree of accuracy and attention to detail. Without proper cost estimation, projects can easily exceed the budget, leading to delays, reduced profit margins, and ultimately project failure.

The construction process is characterized by its dynamic, complex, and time-consuming nature. Within the AEC industry, effective collaboration among all stakeholders is essential for sharing diverse information generated throughout the construction phase. This information includes quantities of physical building components, schedule plans, resource consumption, costs, site layout, safety management, and quality evaluation (Adeli et al., 2001). Cost estimation is a key task involving calculating quantities, and project costs, and classifying essential products within a construction project. Cost estimation is commonly defined as the process of predicting project costs at the operational level, based on detailed design drawings/documents and specific construction methods/specifications. Construction cost estimation is typically carried out separately by construction professionals due to the lack of a well-developed integrated system for both activities (Liu et al., 2014). Despite the existence of advanced technologies for quantitative take-off (QTO), scheduling, and costing, a significant gap remains in seamlessly integrating these activities into a cohesive system. The potential solution lies in a system founded on modeling technologies associated with scheduling and economic management, promising automatic and effective integration (Lu et al., 2016).

In the AEC industry, the standard format for information exchange is the Industry Foundation Classes (IFC), an open international standard developed by BuildingSMART.

Therefore, to support, verify, and improve the quality of cost estimates, in public tendering, and reduce human error-prone, this paper studies how to develop a cost estimation based on IFC.

IFC provides some entities to represent information in building management, including *IfcCostSchedule* (cost planning), *IfcCostItem* (unit cost estimation item), and *IfcCostValue* (value).

A cost estimation (*IfcCostSchedule*) for a structural project has been created including all cost classes (*IfcCostItem*) needed to define a correct estimate of costs. The *IfcCostItems* are linked to the 3D model's geometric objects to determine the quantity of individual works. They are also associated with unitary items in the public works price list (in this specific case of the Lombardy Region's Price List), to establish the unit cost values. The price list items are characterized by a new architecture based on IFC that contains a set of attributes in which information can be instantiated and created. This new architecture of cost items was validated in a previous study by the same research team (Cassandro, et al., 2023). Furthermore, the study carried out seeks to analyse, evaluate, and use the IFC data model to support the economic analysis processes of the projects.

The paper is structured as follows. Firstly, it presents an analysis of the existing literature on cost estimation, including the use of IFC classes, and the IFC standard with a specific focus on the *IfcCostItem* and *IfcCostSchedule* entities (attributes and relations). Currently, no BIM authoring software can write this entity, so it was decided to use the IfcOpenShell library to create the entity and the cost estimation through code. The final step included the validation of the data model generated through IFC viewer/reader, the analysis of the results, the limitations of the study, and future developments.

Literature Review

Cost Estimation Process in Construction

The process of cost estimation involves using available information to estimate the total cost of construction work activities of the project (Ji et al., 2019). Estimating the cost of the project plays a key role in the success of a construction project (Ji et al., 2019), (Jrade & Alkass, 2007). This involves assessing and predicting total costs over a specified period, incorporating all available project information and resources (A. Kwakye, 1994). Initial estimates, with an accuracy of -30% to +50%, are refined at the budget and conceptual level (-15% to +30%) and ultimately at the definitive level (-5% to +15%) (Rast & Peterson, 1999). Cost estimation serves the purpose of providing decision-making information (Carr, 1989).

However, despite the availability of advanced technologies, construction contractors still rely on conventional methods, leading to potential inaccuracies due to factors such as insufficient time and poor tender documentation (Famiyeh et al., 2017).

A cost estimation document contains all work items with a short description, estimated quantities, the unit cost of the repair work, the total cost of each item, and then summing all the items, the total project cost. However, other methods are also developed for estimating construction costs. These include expert systems, artificial neural networks, case-based reasoning, fuzzy logic systems, simulations, statistical regression approaches, decision trees, radial basis function neural networks, and particle swarm optimization (Tayefeh Hashemi et al., 2020).

Cost Estimation Process through IFC

Several studies have explored the applicability of IFC in project planning and cost estimation. Froese T et al. suggested that IFC can effectively represent information related to costs, construction processes, resources, products, and project documents (Froese T et al., 1999). Ma et al. established a BIM-based Construction Cost Estimating (CCE) software framework based on Chinese standards (Ma et al., 2010). Zhiliang et al. investigated the use of IFC standard for construction cost estimating in China, noting the need for extensions in the form of proxy elements and property sets (Zhiliang et al., 2011).

Additionally, Ma et al. discussed key issues for semi-automatic Tendering of Building Projects (TBP) cost estimation using IFC data (Ma et al., 2013). Liao et al. proposed a method to develop a collaborative construction prototype model on BIM software to enhance information-sharing efficiency (Liao et al., 2014). Xu et al. introduced a philosophic position for model-based cost estimation using IFC, emphasizing contextual information and pricing extension (Xu et al., 2013). Xu et al. innovatively used BIM data linked to a project to create items for a bill of quantity for cost estimation (Xu et al., 2016).

Other researchers, including Wu et al., Sacks et al., and Elghaish et al. explored the potential of BIM to enhance cost estimation (Wu et al., 2014), (Sacks et al., 2018), (Elghaish et al., 2020). Staub-French et al. and Lee et al. investigated the use of semantic web technology in BIM-based cost estimation (Staub-French et al., 2003), (Lee et al., 2013) Fürstenberg, et al. delved into how semantic web technology can support automated cost estimation linked to IFC property sets (Fürstenberg et al., 2021).

In the context of cost estimation, current practices often involve connecting codes in digital objects to matching keys with various price items. This process requires different codes for each element generating distinct articles (Pavan et al., 2017).

IFC & Construction Management

Developed by BuildingSMART, the IFC is an open and interoperable standard with a mission to facilitate interoperability across different domains in civil engineering projects. Its objective is to enable the sharing and exchange of project information among various computer applications used by different project participants. Initially released in 1997, the official version, IFC4 ADD2 TC1, became an ISO standard in 2018 (ISO 16739-1:2018). At the beginning of 2024, the new IFC version 4.3 ADD2 - 4.3.2.0 was finally approved by ISO and was published in April 2024 becoming the basis for IFC software certification.

Structured in EXPRESS data specification language or XML, the IFC standard describes actors, processes, controls, resources, and products within the construction domain. The IFC data model is organized hierarchically into four conceptual layers: Resource layer, Core layer, Interoperability layer, and Domain layer. Entities within this model can be related to each other and characterized by a set of attributes, facilitated by the *IfcRelationship* entity. This allows related information to reside either inside or outside the project data.

The IFC standard plays a crucial role in information exchange throughout the project lifecycle in construction or building management projects, serving as a prominent vendor-neutral data schema in the AEC industry. IFC enables the exchange of both geometric and semantic information among different stakeholders and software (Fürstenberg et al., 2021).

In the field of construction management, IFC provides entities like *IfcWorkPlan* (schedule planning), *IfcTask* (construction tasks), *IfcScheduleTimeControl* (task time information), *IfcCostSchedule* (cost planning), *IfcCostItem* (unit items of cost estimation), and *IfcResource* (construction resources such as material, product, labor, and equipment resources).

Methodology

This research aims to define a new method for cost estimation using IFC. The method is based on the use of entities within the IFC standard and the relationships that these can create to develop a cost estimate. Specifically, the method used provides for:

- Definition and structuring of the new architectures of the unit cost of the construction works, contained in the Price List of the Lombardy Region, based on what was validated in a previous study by the same research team (Cassandro, et al., 2023);

- Identification of a case study relating to a structural model in IFC format;
- Development of a code for the implementation of the new cost estimate based on the relationship between IFC classes;
- Identification of the measurement criteria of the unit cost items useful for the correct quantification of the cost items (no manual entry of the quantification rules already defined in the price list).

This methodology will also allow the validation of the IFC model obtained to assess the percentage of correctness in the association of identified cost items and estimated costs. This has already been tested and validated in a previous work of the same research group (Cassandro, et al., 2023). Figure 1 shows the workflow performed in this research.

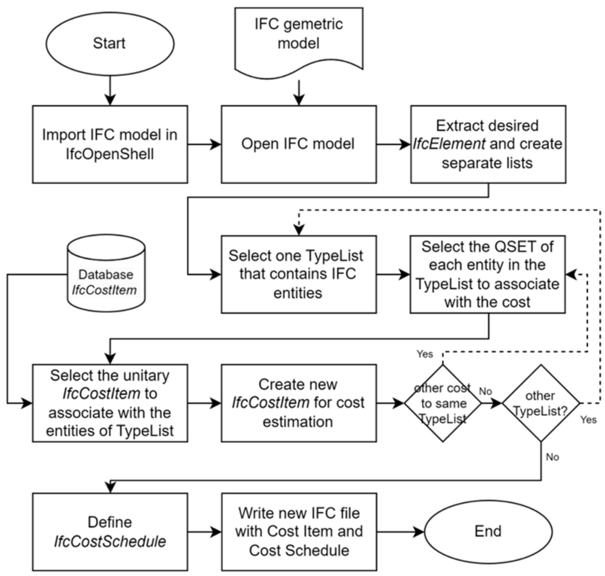

Figure 1: workflow performed in the study

Key Concept

Cost Estimation

According to Samphaongoen, cost estimating is essential for budgeting and tendering in any construction project (Samphaongoen, 2010). It reflects the inherent risks, and direct costs of a project (Olatunji et al., 2010).

The unitary cost of construction works is the sum of the unit costs of resources (materials, labor and equipment), overheads and profits. This sum is calculated through the logic of price analysis and the amount of resources used in the price analysis differs for each construction work. The cost estimate is obtained by multiplying the unitary cost of construction work with corresponding product quantities. The sum of the costs for each construction work provides the total amount of the cost estimate, as shown in equation (1):

$$Cost_i = \sum_{j=1}^{n} (R_j \times Q_j) \qquad (1)$$

Where i denotes the category of construction work, j represents the index of the cost item, n is the number of cost items, R is the unit price of resources from the Price List, and Q represents the quantity for each construction work.

Cost estimation helps stakeholders determine project resources and enables better cost and technology analysis from the start of the design process. Furthermore, it is possible to simplify later phases such as construction and operation by clearly defining cost management (Bryde et al., 2013). So, anticipating economic management during the design phase provides significant advantages for project management (Plebankiewicz et al., 2015).

Generally, the cost estimate can be divided into two distinct phases. These are the physical quantities of design components (volume of concrete columns), that have substantial impacts on the outcome of the cost estimation (Monteiro & Poças Martins, 2013), and the process quantities that are related to specific construction processes (labor hours for concrete casting) (Marzouk et al., 2018). The cost estimation cannot be separated from the extraction of quantities (Aram et al., 2014), (Khosakitchalert et al., 2019). Literature shows that the most used process is to connect the code inserted in the digital objects as matching keys with various price items (Pavan et al., 2017).

The comparison between the traditional estimating process and the 3D BIM-based estimating process is visible in Figure 2 (Sacks et al., 2018).

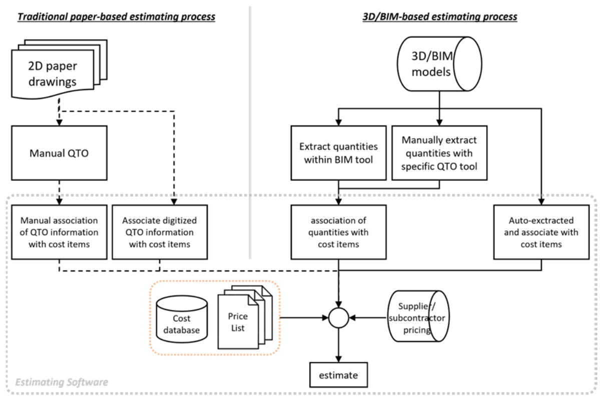

Figure 2: Conceptual diagram of an estimating process

BIM technology has had a revolutionary impact on the conventional QTO process (Smith, 2016). The use of BIM methodology automates and improves QTO processes compared to conventional 2D drawings, resulting in reduced time and errors (Smith, 2016), (Sacks et al., 2018). Nowadays some leading software in the field are Navisworks, CostX, Innovaya, iTWO, Vico, and so on (Abanda et al., 2017).

However, the accuracy of the output quantities from BIM is another major concern (Smith, 2014). The limitations of BIM data hinder a smooth QTO. The material quantities calculated from BIM authoring software rely heavily on the geometry of 3D objects and sometimes may not be sufficient for QTO (Azhar, 2011).

IfcCostSchedule and IfcCostItem

An *IfcCostSchedule* is used to consolidate instances of *IfcCostItem*, for explicit identification of cost information, for example in cost estimation of construction projects.
A Cost Schedule, like all entities in the standard, is also described through a set of attributes (Name, Description, PredefinedType, Status, etc.).
IfcCostItem is the entity that represents the cost of activities and services, the execution of works through a process, life cycle costs, cost estimates, budgets, and other financial aspects within the IFC standard. It functions as a non-geometric entity and is a subclass of *IfcControl*. The *IfcCostItem* abstract entity describes a financial cost or value, including contextual information, in a format that allows its use within a cost schedule.
IfcCostItem is also described through a set of attributes (Name, Description, CostValues, CostQuantities, etc.).
An *IfcCostItem* can link one or many *IfcCostValue's* representing a unit cost, total cost, or a unit cost with one or many quantities used to generate the total cost.

Case Study

The research, to validate the proposed methodology, focused on the implementation of a cost estimate based on the new IFC cost items and an IFC model of a structural project. This model contains 82 objects: 7 *IfcSlab*, 45 *IfcColumn*, 27 *IfcWall,* and 3 *IfcBeam* (Figure 3).

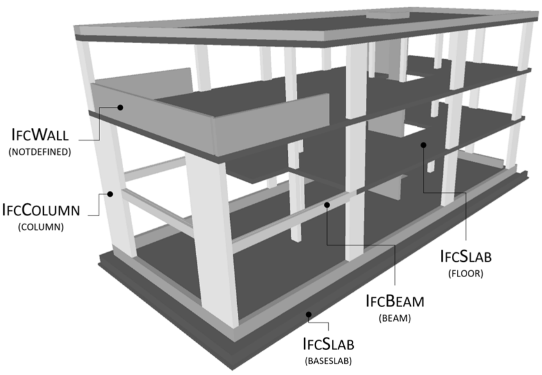

Figure 3: IFC model and the different entities contained

The developed method was implemented using the IFC4_ADD2_TC1 - 4.0.2.1, IfcOpenShell v0.7.0 and Python 3.10.
As a first step, the geometric model was interrogated to identify the IFC classes. The lists of geometric objects based on IFC classes have been identified (*IfcWall*, *IfcSlab*, *IfcColumn*, *IfcBeam*). Subsequently, these were divided into additional sub-lists according to the PredefinedType attribute in the model (for example, all *IfcSlab* were divided into BASESLAB and FLOOR). After that, each sub-list was divided into additional sub-lists according to the Object Type of entities. Finally, a query of these Object Type lists was performed to analyse the entities, verifying the LOADBEARING attribute; this allowed to verify if all objects were characterized by structural properties (LOADBEARING: True) or by non-structural properties (LOADBEARING: False). This analysis was conducted by questioning the "general" PropertySet (Pset) related to each entity, useful for a first verification of the structural model. In Figure 4 an example regarding an IfcSlab.BASESLAB (GUID 1VMFjRH1zBGg8s6Mq2oKI5) with Pset_SlabCommon and property "LOADBEARING: True".

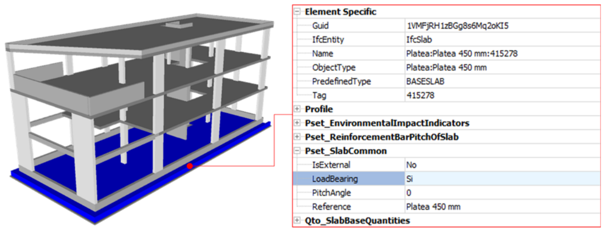

Figure 4: Example of a structural IfcSlab.BASESLAB entity

At this point, the structural objects identified previously were analyzed and through the interrogation of the individual entities, it was possible to extract the relative quantities (*IfcElementQuantity*). However as highlighted in the literature review chapter, quantification is one of the fundamental processes and cannot be based solely on the quantities contained in the 3D model. Therefore, different measurement rules are needed depending on the type of processing that needs to be economically quantified. For this reason, the code developed contains the measurement rules for the correct quantification of cost items according to the type of processing not modifiable by the user (the volume of the concrete casting, the wet surface for laying the formwork, or the weight of the steel for laying the reinforcement bars); in the specific case, these rules are in accord with how much defined in the list prices of the Lombardy Region.
At this point, the analysis performed by the code provides the first of the two manual inputs that the users have to perform. This input is the choice of the construction work (concrete casting, laying the formwork, laying the reinforcement bars, etc.) for which it is necessary to extract the quantity from the IFC model. The user does not need to define measurement rules or perform calculations as the code will perform these operations automatically based on the chosen construction work.
The formulas used by the code, in this case study, to calculate the final quantities contained in the IFC model are summarized in Table 1. These follow the rules defined in the price list of the Lombardy Region for the correct quantification of cost items.
After that, once the quantities were defined (Volume, Wet Area, Weight), the price list was queried. However, this is not a standard price list but a new cost database with cost entities based on IFC. Each of these cost items is characterized by an architecture defined and validated in another study carried out by the research group (Cassandro, Donatiello, et al., 2023). Once questioned, it is possible to identify the unit cost item (*IfcCostItem*) from which to extract the cost value (*IfcCostValue*) useful for the cost estimation and to associate with the geometric object.

Then after the selection of the unit cost item (the second and last manual input), a new cost item (*IfcCostItem*) is automatically created within the new IFC model that updates the previous geometric model and relates to the geometric object. It was possible to define "n" relationships based on how many cost items are necessary for the cost estimation of the specific workings. This new cost item contains the quantity (*IfcPhysicalQuantity*) defined previously according to the rules of measurement of the machining automatically applied by the code from the quantities extracted from the geometric objects and the unit cost value (*IfcCostValue*) extracted from the unitary cost items in the cost database (Figure 7).
Finally, the last step involves the creation of the *IfcCostSchedule* (cost sheet) in which all the cost items previously created have been collected. It will be possible to define an "intermediate" *IfcCostSchedule* to obtain the cost sheet of each set of similar construction work even if related to different objects (for example all C20/25 concrete castings for foundations, beams, slabs, and masonry) and then the final *IfcCostSchedule* corresponding to the entire cost estimate.
This will then be linked to the *IfcProject* and will allow to define the total cost estimate for the structural model.
In the end, a new IFC model was obtained which contains the *IfcCostItem* and *IfcCostSchedule* entities with the cost value and the cost quantity of the construction works for the definition of cost estimation. This new IFC file was validated through the FZK Viewer (Figure 5 and Figure 6).

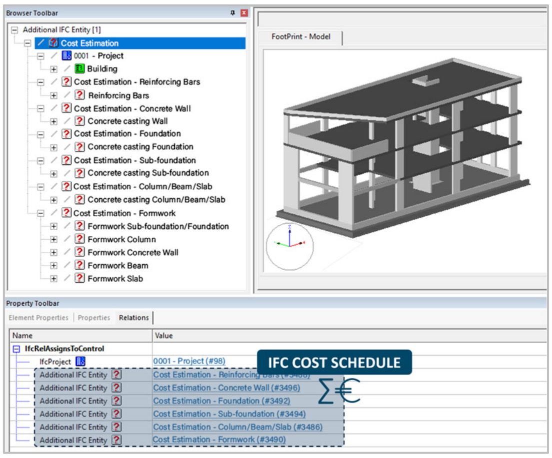

Figure 5: IFC Validation of the cost schedule on FZK Viewer

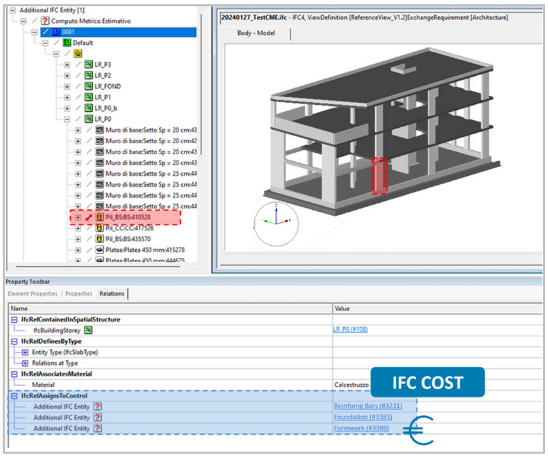

Figure 6: IFC Validation of the cost item on FZK Viewer

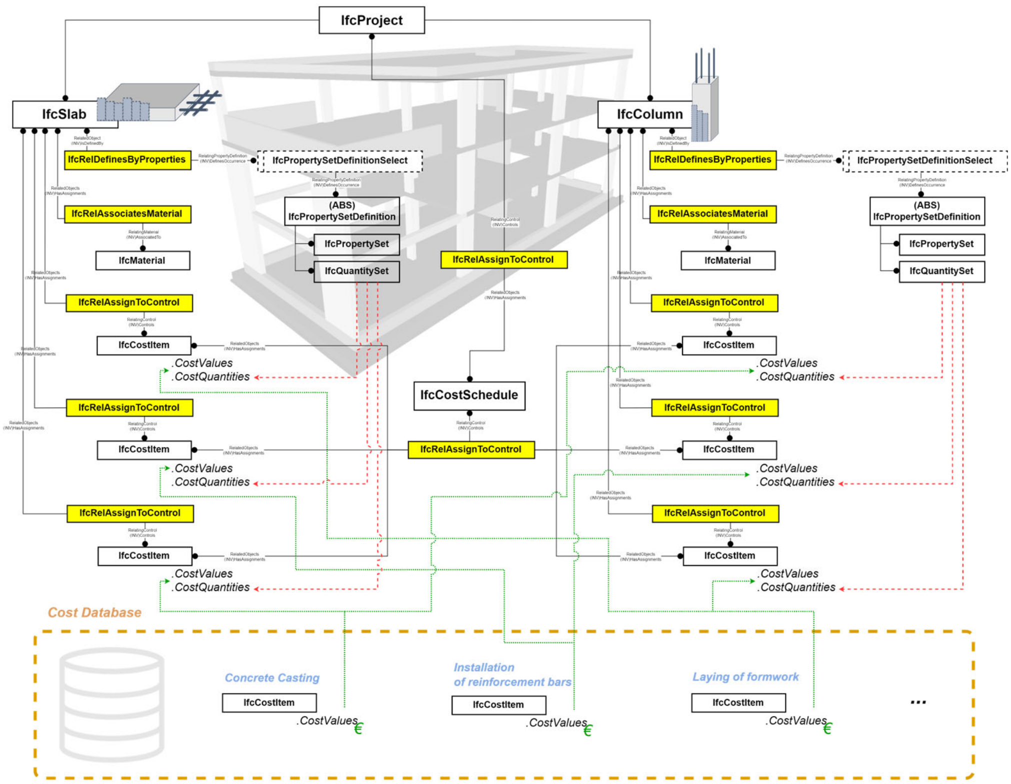

Figure 7: Example of relationships between IFC entities for estimating the costs in IFC of a slab and column

Table 1: Formulas used in the cost estimation process

Working		*Quantity*	*Formula*
Formwork	Slab (foundation)	Wet area[1] [m^2]	Perimeter * Thickness
	Column	Wet area[1] [m^2]	Perimeter * Height
	Wall	Wet area[1] [m^2]	(2*(Length + Width)) * Height
	Slab (floor)	Wet area[1] [m^2]	(Perimeter * Thickness) + (Length * Width)
Reinforcement	General	Reinforcement per cubic metre[2] [kg]	Reinforcement at m^3 * Volume
Casting	Concrete	Concrete casting [m^3]	Volume*1,1

[1] The area is the area of the single face (the height for the length of the septum).
[2] The values used for reinforcement mass per volume unit for each structural element are (Table 2):

Table 2: Theoretical values used for reinforcement mass

Element	*Reinforcement mass per unit volume*
Wall/Floor	200 *kg/m³*
Column/Beam	250 *kg/m³*
Foundation	100 *kg/m³*

Discussion

The research group conducted a study based on the results of ongoing work on a project with the Lombardy Region. The study demonstrates the feasibility of estimating costs based on IFC classes, by relating new cost items structured according to the IFC data model and their geometric objects. The study also validates the use of openBIM methods for cost estimation. This has been made possible through the implementation in IfcOpenShell of the relationship between the new cost items (*IfcCostItem)* with geometric objects (*IfcElement)*, and the creation of the cost schedule (*IfcCostSchedule)* for the identification of the final cost estimate of the entire project (*IfcProject)*.
The methodological and scientific research conducted has led to technological advancements using IfcOpenShell, achieving efficient and scalable outcomes. The proposed methodology can also be applied to estimate the costs of different projects. Currently, these results can be obtained through code, as existing tools do not support user-friendly implementations.
The studied approach, which is based on entity relationships, is effective and flexible compared to the standard approach that uses cost allocation and cost estimation through Excel spreadsheets and associating costs as simple attributes. A reliable and interoperable cost management information base is essential. This process aims to implement and encourage greater data interoperability, not only within the 3D dimension but also extending to the dimension of costs (5D BIM).
The power of the proposed methodology will ensure the possibility of developing cost estimates through procedures that allow the selection in a semi-automatic way of new cost items characterized by a standardized architecture. In addition, it is possible to query this information, verify the correctness of the associations, and relate the cost items to the object automatically. It is no longer necessary to define an attribute for each geometric entity in the geometric model to include cost information.
The cost item will be defined as a single entity related to a specific number of geometric entities within the IFC model by updating it (Figure 6). This avoids duplication of information and ensures respect for the area of knowledge of the different domains.
Furthermore, the *IfcCostItems* are grouped in the *IfcCostSchedule* to create a cost estimate. It is possible to generate different "cost views" by creating multiple cost schedules (Figure 5). This allows the extraction of complete or partial cost estimates from the same model based on specific requirements.
In addition, some problems were identified at the start of the procedure after analyzing and examining the geometric model:

- not all IFC entities had the correct structural property, despite being part of the structural model (LOADBEARING = True);
- some quantities are not stored within the *IfcElementQuantity* entity (volume, perimeter, etc.). This can lead to difficulties in creating standardized automated rules and allocating quantities to cost items. Only standard and hardcoded IFC schema data are evaluated in the research and not proprietary data that may differ between projects.

Therefore, it can be deduced that the issues with cost estimation are not only due to an incorrect cost item selection or association but also due to inaccurate information in the geometric model.

Conclusion

The cost estimation process discussed in this study is based on the IFC standard. It establishes logical connections between products, resources, cost items, and property sets in the IFC data model ensuring greater interoperability of data within the AEC sector through openBIM languages. The possibility of using cost classes (*IfcCostItem* and *IfcCostSchedule*) as independent entities, that are characterized by granular architecture and logical relationships between entities, ensures the possibility of querying, verifying, and validating this relationship to reduce cost estimation errors. It also allows for automatic cost estimation updates by modifying the IFC file of input and identifying changes to cost items or objects without associated cost entities, tracking changes and additions to the project.

During the study, limits were found in the implementation of a standardized methodology for costs. The first is the market barrier with the lack of a user-friendly tool for creating relationships, currently possible through code. A second limitation is the need to have correct information for the realization of a correct estimate of costs; not always the geometric model contains all the information useful for the realization of an estimate of costs, for example, the lack of certain dimensions that do not allow the extraction of certain quantities or the absence of fundamental parameters for the choice of cost items to be reported.

However, this approach must allow for exceptions, as it will not be possible to make all possible cases of cost estimation.

As future work, and already in progress, there is a need to prototype what is studied on a larger scale and with different and more complex geometric patterns, demonstrating how a set of typical costing strategies and economic quantification of projects can easily be implemented in the proposed approach. Develop a user-friendly application with an intuitive interface for a better definition and visualization of this data. Verify the correctness of all the cost items linked to the geometric element. Automate the choice of cost item to reduce the manual input (second manual input in this method).

Data availability

CHATTWIN: ENABLING NATURAL LANGUAGE INTERACTIONS WITH INFRASTRUCTURE DIGITAL TWINS

Peihang Luo, Erika Parn, and Ioannis Brilakis
University of Cambridge, Cambridge, UK

Abstract

Infrastructure lifecycle management requires interactions with dynamic datasets. Traditional interfaces often hinder users' ability to rapidly locate lifecycle-specific information they need. Our work proposes ChatTwin, a system that employs Large Language Models (LLMs) to enable natural language queries related to various lifecycle stages of infrastructure, with a focus on operations and maintenance. Simulated scenarios were constructed to test the system. The results demonstrate that the system can effectively categorise interactions, fetch relevant information, and produce human-friendly outputs. With this LLM-based approach, we present an improvement in user-centricity in infrastructure lifecycle management, streamlining interactions and decision-making throughout the entire infrastructure lifecycle.

Introduction

Modern infrastructure systems are becoming increasingly complex and interconnected, posing significant challenges in their lifecycle management (Grafius et al., 2020). Decisions made throughout their lifecycles require consideration of large amounts of data from various sources. Digital twins have emerged as promising tools to overcome these challenges. They are virtual replicas of physical entities or systems, offering integrated data platforms that enable stakeholders to gain an enriched understanding of infrastructure's behaviour, to optimise maintenance and operation activities, and more (Broo et al., 2022; Rudskoy et al., 2021). Digital twins typically consist of three elements: a physical space where the actual object resides, a digital space that hosts the virtual model, and a connection that facilitates synchronisation and real-time feedback between the two spaces (Barricelli et al., 2019). However, the current human-information interaction paradigms with digital twins remain unintuitive, leading to a steep learning curve and significant investment in training. UK employers invest around £42 billion in training their employees each year, equivalent to an average spend of £2,540 per trainee (Winterbotham et al., 2020). However, even after extensive training, employees can still find it difficult and time-consuming to find the information they need, with employees spending approximately 9.3 hours weekly just sourcing information (Chui et al., 2012). Therefore, the need for more accessible, intuitive interaction methods is clear.

Background

Human-information interaction with digital twins

The interaction between users and digital twins plays a crucial role in leveraging the full potential of these complex and dynamic digital twins. Despite their potential, the current interaction modes between users and digital twins, particularly the mode of natural language interaction, remain underdeveloped. For example, Pairet et al. (2019) present a natural language interface designed for interactions with a digital twin of an offshore platform, facilitating user training across various human-robot collaboration scenarios, but without any results or implementation details. Dingli and Haddod (2019) propose a human interface of an Intelligent Digital Twin system for a semiconductor manufacturing plant, utilising three different modalities: hand gestures, a VR controller, and a voice interaction system. However, no results have been obtained for the performance of the system. Siyaev et al. (2023) introduce a neuro-symbolic reasoning mechanism to interact with a virtual aircraft maintenance digital twin constructed from structured manuals using natural language, which requires a special symbolic vocabulary and a neuro-symbolic dataset of queries to work. Furthermore, to the best of the authors' knowledge, there is no work on the natural language interactions with infrastructure digital twins.

Prompting pre-trained large language models

By enabling users to interact with computer systems using their native language, natural language interactions offer a seamless and accessible interaction experience, particularly for users with limited technical expertise or background knowledge in computing (Pazos R. et al., 2013). Recent advancements in natural language processing, especially the emergence of LLMs, have made it possible to develop more sophisticated and context-aware natural language interaction systems (Wei et al., 2022). Unlike traditional language models, which need to be fine-tuned or even re-trained on specific datasets tailored for individual tasks, LLMs have demonstrated strong in-context learning abilities. This means that they can effectively adapt to new scenarios and perform different tasks by only including a few task-specific input-output examples in the input prompt. This innovative technique is known as "few-shot prompting" (Brown et al., 2020). With few-shot prompting, LLMs can potentially be used for diverse natural language interaction tasks without the need for task-specific models or training datasets. Moreover, LLMs have also demonstrated the ability to perform tasks through "one-shot learning" or even "zero-shot learning" (Kojima et al., 2023). The former involves the LLM accomplishing tasks with just a single input-output example. The latter refers to LLMs handling specific tasks with no examples provided, relying solely on task descriptions in natural language.

While few-shot prompting, one-shot prompting, and even zero-shot prompting have demonstrated competitive performance on various NLP tasks like question-answering or translation (Brown et al., 2020), it has been observed that for complex reasoning and numerical tasks, LLMs may not always provide accurate answers. A widely adopted approach to address this challenge is "chain-of-thought" prompting. This approach provides chain-of-thought demonstrations in prompts to guide the LLM in generating a series of intermediate reasoning steps for a given task. This technique has proven to significantly improve LLM performance on tasks involving intricate reasoning or numerical skills (Wei et al., 2023).

To further enhance the performance of LLMs, some more advanced prompting techniques have also been proposed. For example, "Program-Aided Language models" (PAL) improve LLM performance in arithmetic and symbolic reasoning tasks (Gao et al., 2023). PAL employs the LLM to read and understand natural language problems, generating programs as intermediate reasoning steps based on the problem description. Unlike other methods, PAL offloads the solution step to a runtime, such as a Python interpreter. This allows the LLM to focus solely on decomposing the problem into executable steps.

Gaps in knowledge, objectives & research questions

The gaps in knowledge can be summarised as follows:

1. Domain-Specific Knowledge: LLMs lack specialised domain knowledge related to infrastructure digital twins and infrastructure lifecycle management. This includes domain-specific processes, the specialised knowledge and contextual understanding required to effectively communicate with and interpret information from digital twins, and more.
2. Contextual Information Retrieval: Integrating LLMs with digital twins requires retrieval of relevant information from the digital twin itself. LLMs must be equipped to comprehend the underlying data structure and extract meaningful information and insights from the digital twin's vast repository of information.
3. Effective Prompt Structures: The structuring of prompts plays a pivotal role in guiding LLMs to generate accurate and useful outputs. Understanding how to design prompts that effectively convey the context of a specific query is still an open question to be answered.
4. Usability and Interpretability: Ensuring that LLM-driven interactions with digital twins are not only accurate but also interpretable is critical. Gaining insights into how to post-process LLM outputs to extract valuable information in a user-friendly format is another key aspect to explore.

The primary objective of this project is to enhance human-information interaction with infrastructure digital twins by leveraging LLMs for natural language interactions, contributing to the development of more efficient, accurate, and domain-aware LLM-driven interactions with infrastructure digital twins. With this primary objective in mind, the subsequent research questions have been formulated:

1. What specific techniques can be employed to retrieve relevant information from the digital twin?
2. How can prompts be optimised to ensure that LLMs generate outputs that not only align with the specific requirements of the stakeholder but also maintain a consistent level of accuracy? Moreover, how can the retrieved data be presented to the LLMs within the prompts, ensuring that the LLM understands the broader scenario, background, or situation in which the information is embedded, leading to accurate and context-aware responses?
3. What specific procedures or tools can be employed to most effectively present data or insights to generate tangible value for infrastructure management stakeholders?

Proposed Solution

Scope

This paper focuses on investigating how LLMs can enhance interactions with infrastructure digital twins, enabling them to offer information and insights, and perform certain actions on behalf of users via natural language interactions. This paper prioritises the following five common interaction tasks, using a road digital twin as a case study. Road digital twins are comprehensive virtual models of road systems that replicate their physical counterparts in real-time. These models integrate various data sources to create a dynamic simulation of the road network. This allows for enhanced real-time monitoring, predictive maintenance, and strategic planning (Marai et al., 2021). Although our solution is demonstrated on road networks, it is designed to be adaptable to other infrastructure systems with minimal modifications.

Task 1: Data visualisation

One of the primary functions of road digital twins is integrating data from multiple sources, such as time-series data from meteorological and traffic sensors. Our first goal is to enable users to generate and view visualisations of such time-series data through natural language interactions, enabling them to gain a more intuitive view of the complex information patterns within such data.

Task 2: Information summarisation

Navigating through the vast datasets of a road digital twin to extract pertinent information is often cumbersome and time-consuming. Our system aims to simplify this by summarising key data, like road defect details, in response to user queries in natural language.

Task 3: Performing changes

A frequent and critical interaction with road digital twins is the implementation of changes to the properties of specific instances. This includes, for example, changing the status of a defect from "scheduled to fix" to "fixed" after a repair with a natural language prompt.

Task 4: Model visualisation

Accessing and visualising models, such as point clouds, is another routine task for road digital twin users. This typically involves locating specific files and using dedicated tools. We propose to simplify this process using natural language interaction, enabling users to request visualisations of model sections through simple prompts, enhancing user experience and information access efficiency.

Task 5: Work schedule enquiry

Another commonly performed task for infrastructure digital twins is generating and visualising work schedules. Our work aims to automate these tasks, traditionally a manual and laborious task, through natural language interactions. This automation will facilitate more frequent and accurate schedule adjustments and updates, improving productivity and reducing unnecessary costs associated with outdated schedules.

However, due to the data availability of the demonstrative digital twin, only summarisations of defect information are included in the scope of *Task 2*, and the scope of *Task 5* is only limited to inquiries concerning work schedules of defect rectifications. In addition, this work limits its scope of *Task 3* only to property modifications due to their regularity and natural language compatibility. More complex modifications, such as geometrical alterations or adding new instances, often require assistance from specialised equipment like laser scanners and are thus excluded.

Details

This section outlines the step-by-step process of the proposed solution that enables the user to interact with the infrastructure digital twin using natural language prompts.

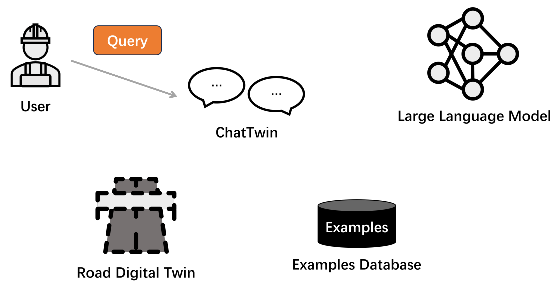

Figure 1: Step 1 - User initiating request

In step 1, as illustrated in Figure 1 above, the user initiates the interaction process by providing a natural language prompt that describes their query or request. Such prompts could either instruct the system to perform specific actions on the digital twin, or request specific data visualisations or summaries.

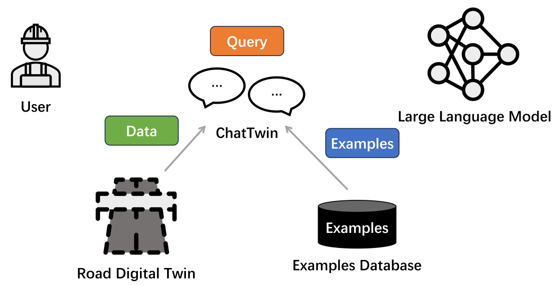

Figure 2: Step 2 - Requesting and receiving relevant data from the Road Digital Twin & Examples Database

In step 2, upon receiving the user's input, the system determines which task category this user prompt belongs to. This categorisation result will determine the subsequent actions of the system. This is done by sending a pre-structured prompt to the LLM. The structure of this prompt can be found in appendix "Prompt for categorising tasks". Depending on the task category, the system fetches relevant data from the digital twin and the examples database (as shown in Figure 2 above). Each task category dictates a unique retrieval process. Further details on the data retrieval process can be found in the "Results & findings summary" section. This aims to solve the first research question, so that relevant data can be correctly retrieved from the digital twin for each of the task categories.

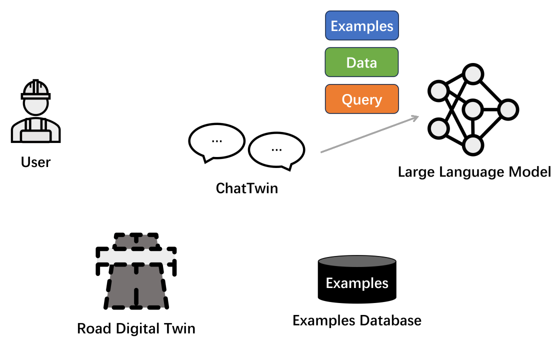

Figure 3: Step 3 - Pre-processing and sending modified prompt to LLM

In step 3 (as shown in Figure 3 above), the relevant data and examples retrieved from the digital twin and the examples database are combined with the user prompt to generate a modified prompt, which is then sent to the LLM. The modified prompt is generated by collating the user's original prompt, the relevant data from the digital twin (if required), and the relevant few-shot training examples from the examples database into a structured prompt. An illustrative example is provided in Figure 8 in the appendix. The prompt starts with one or a few few-shot training example(s) retrieved from the examples database. Each example consists of the relevant data retrieved from the digital twin (if applicable), the user prompt, and the expected task-specific output from the LLM. Additional examples are appended to the end of the previous ones. The second part of the prompt is the relevant data retrieved from the digital twin (if required), and the final part of the prompt is the user's original prompt. The modified prompt is then sent as input into the LLM. This aims to solve the second research question. The examples from the examples database provide the LLM with essential information about the data it works with. This includes but is not limited to the nature of the data, its structure, and the methods to access it. By illustrating this with sample outputs for typical user query inputs, the LLM gains a better understanding of both the data and its context, enabling it to produce more accurate results. In addition, the examples also act as guides for the LLM to ensure that its responses meet the specific needs and standards of different users and situations. This helps in maintaining the relevance and accuracy of the LLM's outputs.

One exception is that for model visualisation tasks, a distinct prompt structure is used to determine whether the requested point cloud data is available within the digital twin, and retrieve the requested point cloud data file if it is available. This prompt structure can be found in appendix "Prompt to retrieve point cloud data".

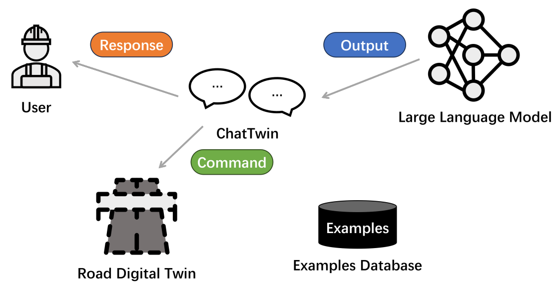

Figure 4: Step 4 - Receiving and post-processing output from LLM

In step 4, as shown in Figure 4 above, an output is received from the LLM, which contains either actionable commands for the digital twin, machine-readable information on the requested information, or a natural language summary of the information requested by the user.

The commands are generated in the form of Python scripts with embedded comments that contain chain-of-thought information. The inclusion of comments helps improve the quality and readability of the generated commands. For tasks where the system is asked to perform specific changes to the digital twin, the LLM will also generate natural language feedback to the user based on the result of the execution of the Python script. For example, if the Python script is successfully executed without errors, the LLM will then provide the user with a "success" message, confirming that the requested actions have been successfully applied to the digital twin.

Otherwise, for example, for information summarisation tasks, the summary generated by the LLM is directly sent to the user, or for model visualisation tasks, the output from the LLM is first analysed - if the output is "Not available", the system will output a message indicating that the requested data is not available within the digital twin, or if the output is the name of the requested data file, the name of the file will be passed into a pre-structured Python script to visualise the requested data. This pre-structured script can be found in appendix "Python script to visualise point cloud data".

This step aims to solve the third research question, so that the data retrieved from the digital twin can be presented to the user in an appropriate form using different tools and procedures, enabling users to quickly gain more value and insights from the data.

Research Methodology

Our work constructs a demonstrative road digital twin to evaluate the proposed interaction pipeline. This twin is populated with four data types: geometric data in point cloud format, time-series sensor data, defect information, and recommended maintenance actions.

Data collection and preparation

The geometric point cloud data, representing a specific road junction in Tallinn, is sourced from the Tallinn City Digital Twin. Time-series sensor data, simulating the input from infrastructure sensors, is obtained from the UK Environment Agency's Real Time flood-monitoring API. This API provides real-time and historical water level and flow measurement data at each of the monitoring stations across the UK. This data is indicative of the real-time sensor data one would expect in a fully operational digital twin. These sensor data have been integrated with the point cloud data, maintaining their properties such as names, IDs, and typical ranges, but changing their location-related properties to correspond with the geospatial location of the point cloud data, so that the sensors are essentially "embedded" into the point cloud at certain locations.

The defect information and suggested actions are stored in text format in a `.txt` file. The information stored within the digital twin about each registered defect includes defect type (e.g. pothole, crack, etc.), defect location (shown as a kilometre number along a specified road), severity level (either severe, moderate, or low), and suggested action based on the severity level (immediate fix for severe defects, schedule fix for moderate severity defects, and monitor progress for low severity defects).

Another component of the system is the examples database. The examples database contains few-shot training examples for each task category. However, not every example contains all three parts (relevant data, user query, and expected task-specific output from LLM). In some cases, no relevant data is retrieved from the digital twin. Instead, time-series data or geometry data are retrieved from the digital twin via Python scripts. Such an example can be found in appendix "An example for *Task 1: Data visualisation* from the examples database", where the system is asked to retrieve and visualise time-series data from a specified monitoring station.

Testing and validation

In order to test and validate the solution proposed in this work, test cases have been constructed for each type of task introduced in section "Scope". One test case has been proposed for each type of task introduced, and the proposed test cases are summarised below:

1. What is the historical water level at the station "Bourton Dickler" for the last 5 days?
2. Are there currently any defects on the road network?
3. Could you please change the severity level of the defect located at M25 28km to "severe"?
4. Could you please visualise the junction of Vabaduse väljak and Pärnu maantee for me?
5. Could you please generate a work schedule based on the current status of the road network?

Implementation details

These test cases are first categorised using a structured prompt (shown in appendix "Prompt for categorising tasks"). Then, they are processed according to their categorisation results. More details can be found in the next section.

The LLM used in this project to generate the results in the next section is the `gpt-3.5-turbo` model developed by OpenAI, and the model is accessed via the OpenAI API with the `openai` Python library.

Discussion

Results & findings summary

This section presents a comprehensive overview of the outcomes and discoveries obtained from the implementation and evaluation of our proposed natural language interaction system with infrastructure digital twin.

First, the task categorisation results are presented in Table 1 below.

Table 1: Expected categories vs actual categorisation results for the test cases

Test Case	Expected Category	Categorisation Result
1	1	1
2	2	2
3	3	3
4	4	4
5	5	5

It can be seen from Table 1 above that the LLM is able to categorise all the test cases correctly.

Then, task-specific results are generated for each of the test cases. For test case 1, the test prompt, together with the retrieved example, are compiled according to the prompt structure introduced in step 3 in section "Details" into an input into the LLM. Then, the output from the LLM, which is a piece of Python script with chain-of-thought comments, is executed in a Python interpreter to produce the visualisation result shown below in Figure 5.

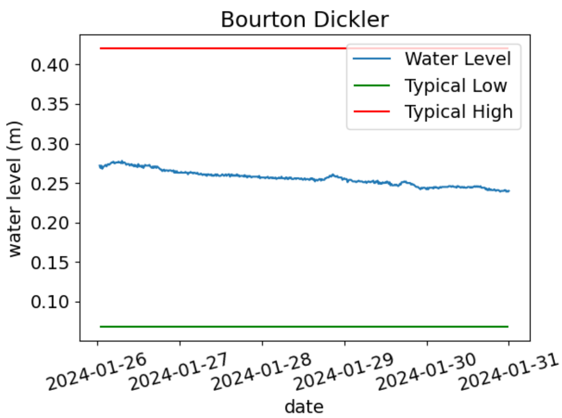

Figure 5: Visualisation result generated by the system

It can be seen from Figure 5 above that a visualisation of the requested time-series data has been successfully and correctly generated.

Then, for test case 2, the test prompt, together with the retrieved example and the defect data retrieved from the digital twin, are concatenated according to the prompt structure introduced in step 3 in section "Details" into an input into the LLM. Then, the output from the LLM is presented below:

```
Yes, I have found a total of 8 defects
```

```
on the road network. Here is a summary
of the defects:

High Severity Defects:
1. Pothole on M25 at 112km

...

3. Crack on A14 at 21km

It is suggested that you prioritize
fixing the high severity defects
immediately, schedule the moderate
severity defects for the next round of
fixing, and monitor the low severity
defects for progress.
```

The full result is available in appendix "Full result for test case 2". It can be seen that the system can retrieve the relevant data from the digital twin and generate a natural language summary. Upon cross-checking with the actual data stored within the digital twin, it was confirmed that the system retrieved the correct information. This verification process involved a comparison between the output generated by the system and the actual defect records within the digital twin. This consistency validates the reliability of the data retrieval process implemented by the system.

Next, for test case 3, the test prompt, and the retrieved example, are combined according to the prompt structure detailed in step 3 in section "Details" into an input into the LLM. The output from the LLM is then executed within a Python interpreter to apply the changes to the digital twin. The system returned a "success" message, and it was verified that the requested change had been successfully applied to the digital twin.

Then, for test case 4, the test prompt, and the point cloud file(s) retrieved from the digital twin, are collated according to the prompt structure in step 3 in section "Details" into an input into the LLM. Then, the output from the LLM, which is the name of the requested point cloud file, is passed into a pre-structured Python script (shown in appendix "Python script to visualise point cloud data") to generate the visualisation shown in Figure 6 below.

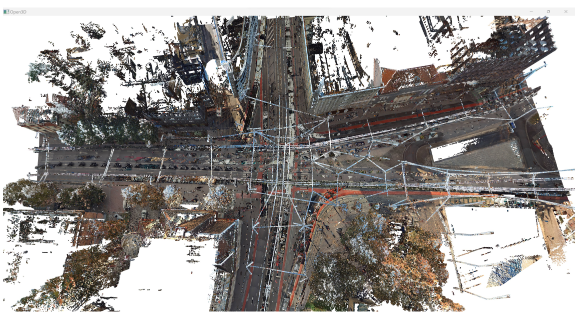

Figure 6: Model visualisation generated by the system

It can be seen from Figure 6 that the system is able to correctly retrieve and visualise the relevant point cloud data requested by the user.

Finally, for test case 5, the test prompt, together with the suggested actions retrieved from the digital twin and the relevant examples, are combined according to the prompt structure introduced in step 3 of section "Details" into an input into the LLM. The output from the LLM is then executed within a Python interpreter to generate the visualisation of the work schedule as a Gantt chart, which is shown in Figure 7 below.

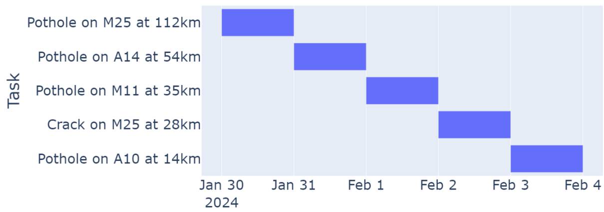

Figure 7: Work schedule visualisation generated by the system

The assumptions and criteria used here were:

1. Only "severe" and "moderate" defects are included in the schedule as the suggested action for low-severity defects is "monitor progress".
2. Prioritise "severe" defects over "moderate" defects.
3. Within "severe" and "moderate" defects, prioritise "M" roads over "A" roads.
4. Within "M" roads and "A" roads, prioritise roads with a smaller road number assigned to them.
5. Within each road, schedule the tasks according to the location of the defects, and work along each road from the defect with the smallest km number to the defect with the largest km number.
6. The time for fixing each defect is one day.

These parameters and criteria can be changed easily within the digital twin and ChatTwin to reflect the real situation. The assumptions are made purely for demonstration and to validate the results generated by the system, and do not reflect any real circumstances in the real world. It can be seen from Figure 7 above that the system is able to generate a correct work schedule according to the pre-set criteria and visualise it as a Gantt chart.

Contributions

Our work presents a novel approach to enhance the human-information interaction with infrastructure digital twins by leveraging the capabilities of LLMs, filling gaps in both the fields of digital twin research and human-computer interaction (HCI), as detailed in the following two paragraphs.

First, this work fills the gap in digital twin research by proposing a systematic approach to structure prompts that effectively leverage LLMs for generating informative and contextually relevant outputs with infrastructure digital twins. This enables the LLMs to perform domain-specific tasks without the need for extensive fine-tuning. Our work contributes to the growing field of prompting pre-trained LLMs, providing some structured templates for structuring prompts that effectively guide the responses of LLMs within the context of infrastructure digital twins. This work also presents an empirical evaluation of our LLM-based interaction system through scenario-based simulations, demonstrating its strengths, limitations, and potential areas of improvement, offering valuable insights for researchers and practitioners interested in advancing natural language interaction with digital twins in the domain of infrastructure management.

In addition, current infrastructure digital twin research often emphasises technical aspects. This work primarily enhances the interaction layer, bridging the gap between intricate domain-specific data in digital twins and straightforward, user-friendly interactions, adding a user-centred design perspective, and aligning the infrastructure management domain with foundational HCI principles by facilitating more intuitive communication with digital twin systems, further enhancing the capabilities of conventional digital twin systems. This paves the way for stakeholders to more effectively engage with digital twin systems for infrastructure monitoring, control, and decision-making.

Conclusions

The integration of LLMs with infrastructure digital twins has far-reaching implications for the infrastructure management domain and beyond. By providing a more accessible, intuitive and user-friendly interface, LLM-driven interactions reduce the learning curve required to interact with intricate infrastructure digital twin systems, empowering decision-makers at different levels, from engineers to policymakers, with timely and contextually relevant insights. This improved decision-making capability, supported by real-time data analysis and predictions provided by the capabilities of digital twins, can lead to more informed choices regarding infrastructure management, maintenance, and resource allocation.

Recommendations for future

While our research provides valuable insights, some limitations remain. This section lists some potential areas for further investigation.

Enhancing interaction feedback

While the current system can successfully generate and execute Python scripts for requested actions on the digital twin, future improvements can focus on providing more comprehensive feedback to users throughout the process to enhance user engagement and make the interface more informative. This can involve monitoring the digital twin's status during and post-execution, enabling the system to confirm the successful implementation of user requests or flag potential issues, thus ensuring the accuracy of performed actions. Users might receive a visual cue for successful operations, or a notification detailing any encountered challenges. This could establish a closed feedback loop and eliminate ambiguity about action outcomes. Potential research questions could include: How can real-time feedback during task execution enhance user trust and system transparency for users of different expertise levels? What impact does visual or textual feedback have on user comprehension and satisfaction?

Expanding task categories

While this project addresses the five most common tasks associated with infrastructure digital twins, there exists substantial potential to broaden the range of tasks covered by this approach. Expanding beyond these fundamental tasks can further improve system applicability. Furthermore, with the ReAct (Yao et al., 2023) approach, there is also potential to develop a more generally applicable natural language interaction system. Such a system could leverage the advanced reasoning capabilities of LLMs to autonomously deduce steps for various user-initiated actions beyond pre-defined task categories.

Multi-turn interactions and task clarification

The current focus of the project on single-turn interactions provides a solid foundation for future research exploring more complex multi-turn conversations. This expansion will enable the system to engage in more intricate and dynamic interactions with users, improving the adaptability of the system. This extension is particularly crucial for addressing scenarios that involve ambiguity and might require additional clarification. In such cases, the system can proactively seek clarification from users when faced with potential misunderstandings to help disambiguate potentially confusing queries. Moreover, multi-turn interactions could also be leveraged to handle situations where users require assistance in accurately conveying their intent. With multi-turn interactions, the system's ability to interact, interpret, and execute user intents can be significantly enhanced, ultimately contributing to a more effective and user-centric infrastructure management system. Potential research questions could include: How do multi-turn interactions influence user experience and system accuracy in complex query scenarios? What methodologies can effectively disambiguate user queries?

User-centric design evaluation

Future enhancements can be rigorously user-tested in simulated and controlled real-world scenarios to validate their effectiveness and user-centricity. This approach will ensure that proposed improvements align with actual user needs and preferences, thereby enhancing the practical applicability of our findings.

Evaluating performances with different LLMs

OpenAI's `gpt-3.5-turbo` model has been used in this work. In the future, tests can be conducted on other LLMs (e.g. PaLM, BERT, and Llama) to evaluate and compare the effectiveness of the system with different LLMs.

Acknowledgements

The authors gratefully acknowledge the EPSRC, Bentley Systems and the University of Cambridge for funding this research through the EPSRC Centre for Doctoral Training in Future Infrastructure and Built Environment: Resilience in a Changing World (EPSRC grant reference number EP/S02302X/1); and Christopher-Robin Raitviir and Andres Maremäe from Tallinn City Council for generously providing data from the Tallinn City Digital Twin. This work also uses Environment Agency flood and river level data from the real-time data API (Beta). For the purpose of open access, the authors have applied a Creative Commons Attribution (CC BY) licence to any Author Accepted Manuscript version arising from this submission.

Appendices

Prompt for categorising tasks

```
Please determine which task category this user prompt belongs to: [user prompt]

-----

Candidate task categories:

Task category 1: Data visualisation
Task description: Tasks where the user asks the system to visualise specific
time-series data
Example user prompt: What is the water level data at the station "Cam" over the past 2
days?

Task category 2: Information summarisation
Task description: Tasks where the user asks the system to find and summarise certain
data or information
Example user prompt: Are there currently any defects on the road network?

Task category 3: Performing changes to digital twin
Task description: Tasks where the user asks the system to change the property value of
a specific instance within the digital twin
Example user prompt: Can you change the status of the defect at M2 112km to fixed?

Task category 4: Model visualisation
Task description: Tasks where the user asks the system to visualise a certain section
of the digital twin model
Example user prompt: Can you show me a visualisation of Regent Street between 5km and
8km?

Task category 5: Work schedule enquiry
Task description: Tasks where the user asks the system to generate/visualise a work
schedule
Example user prompt: Could you generate a work schedule for defect rectification?

-----

Please only respond with the task category number in Arabic number.
```

Prompt to retrieve point cloud data

```
The available point cloud data files are:
[the available point cloud data retrieved from the digital twin]
The user's query is: [user query]
Is the point cloud data requested by the user available? If it is available, please
only respond with the name of the corresponding point cloud data file. If it is not
available, please respond with "Not available".
```

Prompt structure

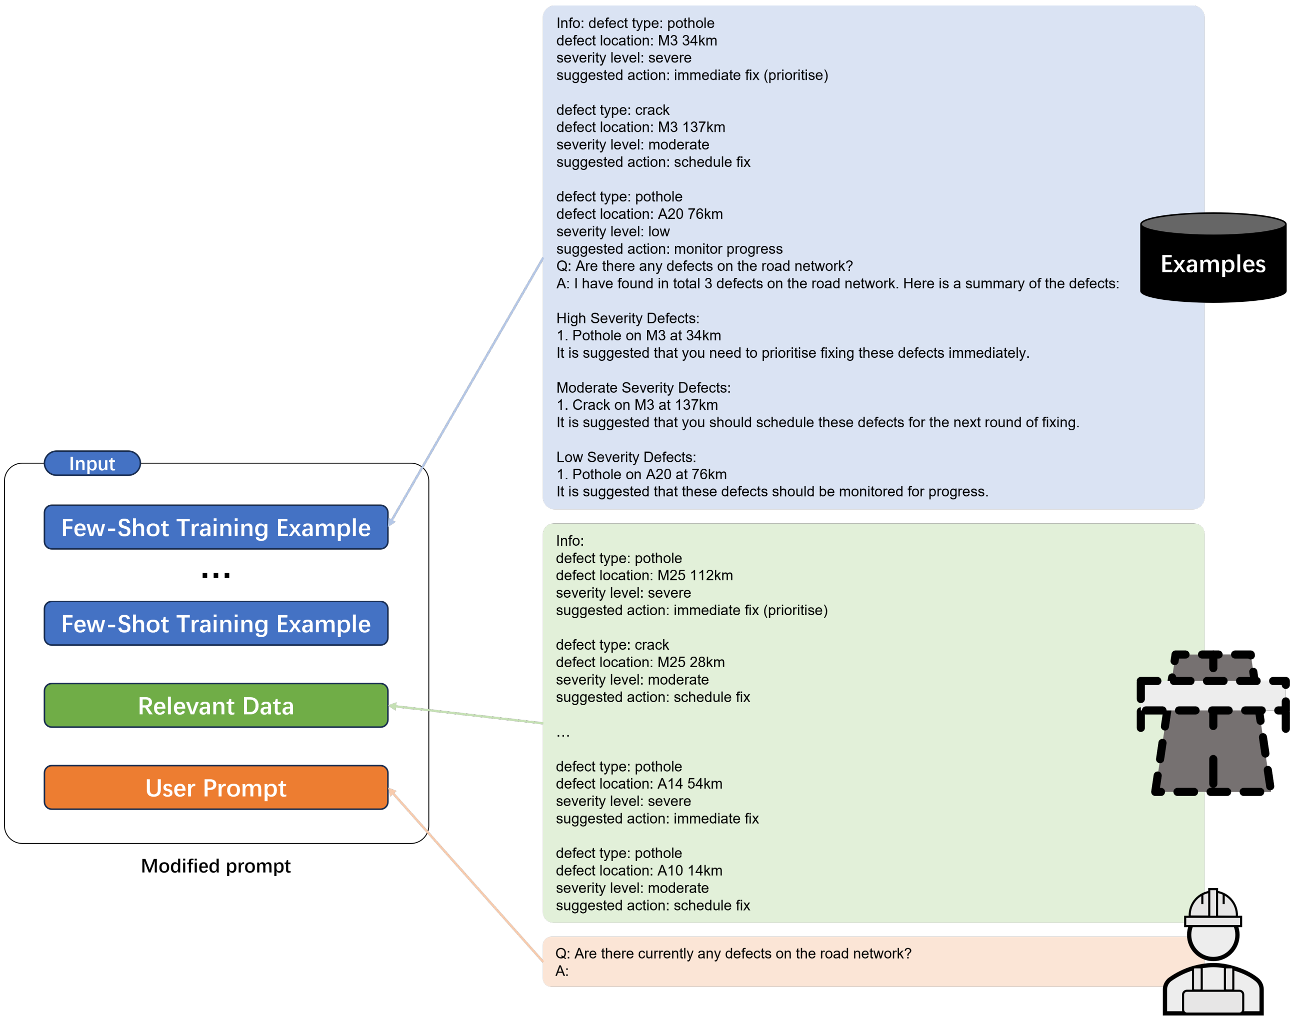

Figure 8: Prompt structure

Python script to visualise point cloud data

```python
import open3d as o3d

point_cloud_file = response["choices"][0]["message"]["content"]
top_dir = "[path to the top directory of point cloud data files]/{}"
path = top_dir.format(point_cloud_file)
pcd = o3d.io.read_point_cloud(path)
o3d.visualization.draw_geometries([pcd],
                                  zoom=0.4012,
                                  front=[0.0902, 0.2108, 0.9734],
                                  lookat=[130.1986, 20.4945, -13.5578],
                                  up=[-0.1271, -0.9669, 0.2211])
```

An example for *Task 1: Data visualisation* from the examples database

Q: What is the water level data at the station "Cam" over the past 2 days?
A:
```
# To get water level data, we first need to find the list of monitoring stations using
the function build_station_list()
stations = build_station_list()
# Then we need to find station "Cam" from the list and store it in the variable
station_cam
station_name = "Cam"
for station in stations:
  if station.name == station_name:
    station_cam = station
    break
# We then need to fetch the water level data over the past 2 days using the function
fetch_measure_levels
dt = 2
dates, levels = fetch_measure_levels(station_cam.measure_id,
dt=datetime.timedelta(days=dt))
# We can then finally plot the water level data using the function plot_water_levels
plot_water_levels(station, dates, levels)
```

Full result for test case 2

```
Yes, I have found a total of 8 defects on the road network. Here is a summary of the
defects:

High Severity Defects:
1. Pothole on M25 at 112km
2. Pothole on A14 at 54km

Moderate Severity Defects:
1. Crack on M25 at 28km
2. Pothole on M11 at 35km
3. Pothole on A10 at 14km

Low Severity Defects:
1. Pothole on M11 at 87km
2. Pothole on M11 at 134km
3. Crack on A14 at 21km

It is suggested that you prioritize fixing the high severity defects immediately,
schedule the moderate severity defects for the next round of fixing, and monitor the
low severity defects for progress.
```

RECOMMENDATIONS FOR PRIVATE AND SECURE CDE BASED BIM COLLABORATION

Anja Brelih and Robert Klinc
University of Ljubljana, Faculty of Civil and Geodetic Engineering

Abstract

The digitalization of the construction industry through BIM and CDE raises security and privacy concerns as sensitive data is stored in cloud environments. It is critical to address these concerns related to CDE and provide guidelines and recommendations for users. The paper provides an overview of security and privacy mechanisms at multiple levels that should be implemented in BIM, including data and network security, identity and access management, physical security, and compliance with standards. We examine ISO 19650-5 and recommend a direction to improve BIM related guidelines in order to help users identify potential concerns in their chosen cloud environment.

Introduction

A Common Data Environment (CDE) is a cloud computing infrastructure that serves as a shared digital workspace for project teams to collaborate on Building Information Modelling (BIM). CDE is becoming increasingly important in the construction industry as it provides a centralised repository for managing project information and improving communication between stakeholders (see Figure 1).

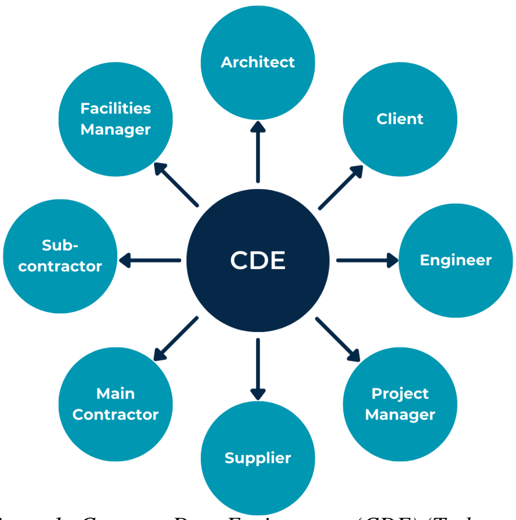

Figure 1: Common Data Environment (CDE) (Turk et al., 2022).

CDEs allow project teams to access and share BIM models and other project data in real time. This can help to improve coordination, reduce errors and shorten project timelines.

Cloud computing is a ubiquitous and rapidly growing computing paradigm that provides users with access to data and applications. Two main models are private and public clouds. In the private cloud, ownership and management of the cloud is in the hands of the organisation providing the applications and access to the resources is not open to everyone as in the public cloud. Cloud computing offers different service models, which are a specific, pre-prepared combination of information technology (IT) resources offered by a cloud service provider and relate to the way in which it offers a service to users. The three main service models are Software as a Service (SaaS), Platform as a Service (PaaS) and Infrastructure as a Service (IaaS) (Manvi and Shyam, 2021). Shared digital workspaces used in the construction industry are typically offered as a SaaS model, where users do not manage and control the cloud infrastructure, but simply utilise cloud software solutions. In commercial CDE environments, providers are responsible for managing the SaaS model and providing upgrades, maintenance and security.

The exponential growth of cloud computing brings numerous benefits, but also a number of security concerns that must be properly understood and addressed in order to successfully deploy solutions in the cloud environment (Sun, 2018). Computing and data in the cloud are associated with various security risks, including loss of governance, isolation failures, data protection, service availability, compliance and legal risks, authentication and authorisation, etc. Cloud computing security refers to maintaining the confidentiality, integrity and availability of data stored in the cloud. Cloud security requirements include robust security, trust, safety, monitoring and governance (Pavithra et al., 2019). These requirements can be directly applied to the security and privacy requirements for CDE environments in the cloud.

This paper provides recommendations for secure and private CDE based BIM collaboration environments. The second chapter provides an overview of the levels of security and privacy mechanisms that need to be implemented in these environments. The third chapter provides an overview of the ISO 19650-5 standard for Security-minded approach to information management. The fourth chapter gives an overview of the BIM Execution Plan with guidelines for users. Chapter five proposes guidelines for users of BIM and CDE environments. The last two chapters provide a discussion and a conclusion.

Cloud Computing Security and Privacy Mechanisms

As the use of BIM and CDE environments increases, so does the number of security risks and threats that need to be addressed and successfully mitigated. These mechanisms are crucial to ensure the aspects of data security, i.e. confidentiality, integrity and availability of data in the cloud, and provide protection against unauthorised access, data loss and cybersecurity threats (Manvi and Shyam, 2021).

The security and privacy mechanisms of cloud computing must be considered on multiple levels in order to provide users with a comprehensive and trustworthy service. In this paper, the mechanisms are categorised into data security, network security, identity and access management, physical security and standards compliance (see Figure 2).

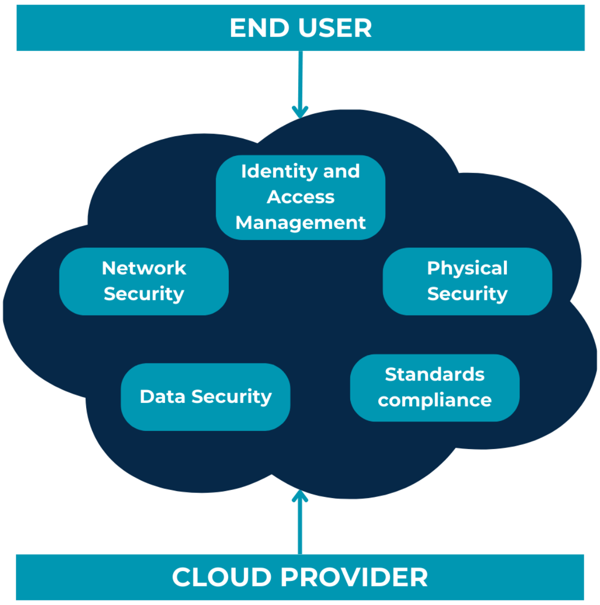

Figure 2: Cloud computing security levels.

Data security

Data security in the cloud differs from traditional data security due to its special storage architecture. Cloud computing generally uses distributed storage. Ownership and control of the data are separated. Users have ownership, but control lies with the cloud service providers. Current data protection in the cloud mainly focuses on data storage, transmission and access authentication and is mostly implemented using cryptography (Xu et al., 2019). By default, data is written in a human-readable format known as plain text, which is vulnerable to unauthorised and potentially malicious access when transmitted over a network. Cloud encryption converts the data into a unreadable format to ensure confidentiality and even data integrity. It is a service offered by cloud storage providers that uses encryption algorithms (Manvi and Shyam, 2021) to convert data into a protected and unreadable form, rendering the encrypted data unusable without knowledge of the key. The encryption process can be carried out using various techniques such as symmetric and asymmetric encryption. In symmetric cryptography, the same key is used for encryption and decryption, as opposed to asymmetric cryptography, where a pair of public and private keys is used for encryption and decryption. An important aspect of data security during transmission or remote storage is maintaining the integrity of the data. To this end, hash functions can be used to ensure that the data received is identical to the original.

Network security

Network security includes the protection of data transmitted over networks such as the internet, the protection of systems and data from network attacks and the protection of the network components themselves. A cloud service provider can ensure the security of the network environment for users by offering cloud services that ensure encryption of data traffic, network monitoring, analysis and control of data traffic, virtual private networks (VPN), firewalls and secure network services (CSA, 2012).

Identity and access management

Cloud computing has had a significant impact on identity and access management (IAM). In both public and private clouds, two parties must work together to manage IAM without compromising security. Cloud computing requires significant changes to the methods used to manage IAM for internal systems. The most important difference is the relationship between the cloud provider and the cloud user. IAM cannot be managed by just one or the other, so a mutually agreed understanding of responsibilities and a secure relationship for managing identity, authorisation and access (CSA, 2021a).

Physical security

Physical security mechanisms include various levels of control and measures to control access and activities. The cloud service provider, who has control over the physical infrastructure, is responsible for ensuring this level of security. It must ensure security against physical attacks as well as natural disasters and power outages. Every aspect of the data center, from location and accessibility to power density and redundancy, must be designed to ensure its security, resilience and efficiency. However, incidents can still occur, whether through a natural disaster, a physical attack or a cyber-attack. It is therefore important that cloud providers are prepared for such situations and have disaster recovery mechanisms in place to ensure business continuity.

Shared responsibility model

The Cloud Security Alliance (CSA, 2021b) identifies the so-called shared responsibility model, which is directly related to two recommendations for security in cloud applications:

1. Cloud providers should clearly document their inter-

nal security controls and characteristics of customers so that the cloud user can make an informed decision. Providers should also properly design and implement these controls.

2. Cloud users should create a responsibility matrix for each individual project to document who implements which controls and how.

The shared responsibility model states that when dealing with cloud computing technology, there are two parties involved who are responsible for implementing and managing different parts of the stack. Building and maintaining trust is critical to this relationship.
Cerić et al. (2021) provide a detailed analysis of the existing literature on trust in megaprojects. The authors identify three different approaches to the study of trust. Namely the psychological, the sociological and the economic. The psychological approach focuses on the dynamics of trust dynamics, while the sociological approach examines trust within groups and organisations. The economic approach, on the other hand, analyses how trust influences economic interactions. The key factors that contribute to trust in such projects are effective communication, transparency, reputation and strong relationships.
Trust is an important aspect of construction projects and it also applies to the collaboration of all parties using or providing BIM and CDE cloud environments. A trusting relationship is important for the successful implementation of these solutions so that the parties involved regulate and respect the activities of the shared responsibility model.
The basis for establishing and maintaining trust in BIM and CDE cloud computing environments between the parties involved in the projects must be clearly defined in the standards and project documentation. The ISO 19650 series of standards focuses on the management of information throughout the lifecycle of a built asset using BIM (BSI, 2023). The clear instructions for managing the security and privacy of the information should also be part of the project documentation, e.g. the BIM Execution Plan.

Standards compliance

In addition to the ISO 19650 series of standards that apply to information management using building information modelling, CDE environments must also comply with the standards that apply to cloud computing. Cloud computing has attracted increasing attention due to security concerns and standardised validation and certification is required to assess cloud security. IT security standards are a structured approach to IT security based on measurable indicators represented by controls (e.g. a checklist) or general but clear requirements (e.g. clauses or principles) Di Giulio et al. (2017). The ISO/IEC 27000 family is the most widely used standard for information security management systems (ISO, 2023). It contains guidelines for the establishment, implementation, maintenance and continuous improvement of an information security management system. The ISO/IEC 27001 standard provides instructions for the establishment, implementation, maintenance, and continuous improvement of an information security management system. Compliance with the ISO/IEC 27001 standard means that the organization or company has established a system to manage risks associated with the security of data held or processed by the company, and that this system complies with all the best practices and principles described in this international standard (ISO, 2022a). In addition to compliance with the ISO/IEC 27001 standard, consideration should also be given to compliance with the ISO/IEC 27017 standard, additional controls with implementation guidance that specifically relate to cloud services (ISO, 2015). It is intended to complement the recommendations of the ISO/IEC 27002 (ISO, 2022b) standard and various other standards in the ISO/IEC 27000 family, such as ISO/IEC 27018 on the privacy implications of cloud computing (ISO, 2019) and ISO/IEC 27031 on business continuity (ISO, 2011). The ISO/IEC 27018 standard focuses on the protection of personally identifiable information (PII) in public clouds that serve as PII processors (ISO, 2022a). Compliance with these standards demonstrates that an organisation has implemented a robust security management system and is essential for ensuring the security of data and information in CDE environments.

ISO 19650-5 standard

The fifth part of the ISO 19650 *"Organization and digitization of information about buildings and civil engineering works, including building information modelling - Information management using building information modelling"* series of standards refers to *"Security-minded approach to information management"*. This part of the standard outlines the requirements for the management of information security in BIM projects (ISO, 2020).

ISO 19650-5 provides a framework to help organisations assess security vulnerabilities in BIM and implement controls to mitigate risk. It recognises that the use of BIM and information management technologies introduces new vulnerabilities that need to be proactively addressed. The standard promotes a risk-based approach to security that can be applied across the organisation. It is designed to help organisations protect sensitive information and ensure the security and resilience of assets, products and services in the built environment (ISO, 2020).

The main part of the standard is divided into six parts, which establish the need for a security-minded approach and provide guidance on developing a security strategy, a management plan with a plan for dealing with security breaches and outline guidance for working with appointed parties. In addition, the standard also contains annexes with further information on (1) the security context, (2) the types of personnel, physical and technical security controls and the management of information security, (3) the assessment in relation to the provision of information to third parties and (4) information sharing agreements.

BIM Execution Plan

The BIM Execution Plan (BEP) is a comprehensive document that helps project stakeholders move forward with clear roles and expectations. It is an essential element that must be created before a construction project begins, and it is a powerful tool for project ownership that drives work through the various design and construction phases. Information that should be included in the BEP includes (1) how the data in the BIM files will be created, managed, documented and shared, (2) elements such as agreed roles and responsibilities within the BIM process, (3) a strategy for key deliverables and a guide to key project milestones, and (4) practical working procedure details. The BEP is a guiding document that helps the different team members to identify and execute the various phases of the project. It can help to present a clear plan with goals and objectives for each step (Ramage, 2022).

Ramage (2022) identifies seven elements of a good BEP: (1) clearly defined roles and responsibilities of each team and organisation, (2) strategic planning, definition of BIM scope and defined key deliverables, (3) project milestones and a realistic timeline, (4) project objectives, (5) model quality control procedures, (6) project reference information with key project contacts, and (7) working procedures that include file naming conventions, construction tolerance expectations, the project approach to annotation, technology infrastructure needs (including hardware and software used), BIM iteration management and data transfer management.

In the third version of the BIM Project Execution Planning Guide (Messner et al., 2021), the authors offer a structured procedure for the creation and implementation of the BEP. The five steps within the procedure include:

1. defining the goals for the implementation of BIM,
2. identifying high value model uses during the project planning, design, construction and operational phases,
3. designing the BIM execution process through the creation of process maps
4. defining the information deliverables, and
5. the development of infrastructure in the form of contracts, communication procedures, technology and quality control to support implementation.

These steps describe the general application of BEP in a project. While steps 1 to 4 mainly contain guidelines for BIM implementation and project-specific organisation, step 5 refers to the technology used. It is essential that this step includes the definition of the required level of security and privacy required, the technologies used and the responsibilities. The requirements for the technological aspect must also be the subject of the contract between the provider and the customer.

The BEP also provides guidelines for defining the infrastructure needs, including hardware, software, networks and modelling content for the project that will be used for BIM. It identifies fourteen specific categories to support the BIM project execution process.

1. **BIM Project Execution Plan Overiview**: review of the plan based on the categories developed after analysing the documents listed below, reviewing current execution plans, discussing the issues with industry experts and revising through a comprehensive review by various industry organisations.
2. **Project Information**: contains basic project information that can be useful for current and future projects. It can be used to introduce new members to the project and help others reviewing the plan to understand the project.
3. **Key Project Contacts**: contains the contacts of the owner, the planners, the consultants, the main contractors, the subcontractors, the manufacturers and the suppliers of the project.
4. **Project Goals / BM Uses**: the plan should include a clear list of BIM goals, the BIM Use Analysis Worksheet and specific information on the selected BIM Uses selected.
5. **Organisational roles / Staffing**: for each selected BIM Use, the team must specify which organisation(s) will staff and perform this Use. This includes the number of staff by job title required to perform the BIM Use, the estimated working hours, the main location where the use will be performed and the lead organisational contact for this Use.
6. **BIM Process Design**: the plan should include the overview map of BIM Uses, a detailed map of each BIM Use and a description of the elements on each map.
7. **BIM Information Exchanges**: the team should document the information exchange created as part of the planning process in the BIM Project Execution Plan. The information exchange illustrates the model elements by discipline, level of detail and any specific attributes that are important to the project.
8. **BIM and Facility Data Requirements**: project owners can have very specific BIM requirements. It is important that the plan documents the BIM requirements in the format specified by the owner.
9. **Collaboration Procedures**: the team must develop its procedures for electronic and active collaboration. This includes the management of models and standard meeting actions and agendas.

10. **Quality Control**: procedures must be defined and implemented to ensure model quality at each project stage and prior to information exchange. Each BIM created during the life cycle of the project must be pre-planned taking into account the model content, the level of detail, the format and the party responsible for the updates and distribution of the model and data to various parties.
11. **Technological Infrastructure Needs**: the team should determine the requirements for hardware, software platforms, software licences, networks and modelling content for the project.
12. **Model Structure**: the team must determine the methods that will ensure the accuracy and scope of the model. Once the planning team has agreed on the collaboration methods and technology infrastructure needs, it should reach a consensus on how the model will be created, organised, communicated and controlled.
13. **Project Deliverables**: the project team should consider what deliverables are required by the project owner. Deliverables should take into account the project phase, the format of the due date and any other specific information about the deliverable.
14. **Delivery Strategy / Contract**: When implementing BIM in a project, attention should be paid to the delivery and contract methods before the project begins.

Guidelines for users of BIM and CDE environments

As BIM and CDE environments contain sensitive information about construction projects, especially financial information, intellectual property and personal data. It is therefore important for providers and users of these environments to take measures to protect the security and privacy of this data.

Users should be aware that BIM and CDE environments are based on new cloud technologies. It is important to verify the provider's compliance with industry standards. By demanding compliance with the standards, users can help to ensure that providers adhere to the rules and standards and clearly communicate these to their users.

Users need clear guidelines on how to use cloud solutions correctly in their projects. Based on current standards and guidelines, users should pay particular attention to the following list that can help protect the security and privacy of sensitive data in BIM and CDE environments:

- **Make a conscious decision about the data you share**. Only share the data that is necessary for the project. Ask questions about the security of the environment snd consult security experts.
- **Assign a data security officer for the project**. This person should be responsible for monitoring the security of the data.
- **Research the provider's security and privacy mechanisms**. Before deciding on a cloud-based CDE, find out about the provider's security practises. Look for providers that are certified to industry standards.
- **Request documentation**. Ask for documentation from the provider outlining security practises.
- **Negotiate the terms**. Include the security requirements and consequences in your contract with the provider.

Discussion

ISO 19650-5 is a valuable standard that provides a framework for information security in information management with BIM. However, the standard could be improved by focusing more on cybersecurity, providing more clarity and consistency, and offering more detailed guidance on how to implement security measures. In particular, the standard should address cybersecurity risks associated with cloud-based technologies, provide clearer and more specific guidance, and offer more specific recommendations for policies, procedures and tools. By improving the standard, organisations using BIM and CDE and providers can better protect sensitive information.

The BIM Execution Plan outlines an important procedure for BIM implementation in construction projects. However, it only focuses on the specifics of construction projects and does not take into account the information security and privacy required when using CDE cloud environments. An important aspect that is ignored is the use of suitable providers that can guarantee an appropriate level of security and meet the required standards for cloud environments.

The shared responsibility model used in cloud environments should be included in the BEP, as it clearly defines which aspects both the provider and the user must guarantee and take into account. It would also be necessary to include in the BEP specific cloud computing technological aspects that are necessary to ensure security and privacy. Experts in the construction field do not focus on information security aspects. Therefore, collaboration with relevant experts in the field of information security and privacy is crucial, as construction projects involve a large amount of often sensitive information.

Conclusion

The use of BIM and CDE environments in construction projects is becoming increasingly common and serves as an important tool for more efficient project management and resource management. With the use of these cloud technologies, it is also of paramount importance to ensure robust security and privacy mechanisms to ensure the confidentiality, integrity and availability of data.

In this paper, we have explored the key aspects of ensuring security and privacy in cloud environments where the user does not have full control over their data in public clouds.

A review of the ISO 19650-5 standard, which focuses on the security-minded approach to information management, has shown that it does not provide adequate guidelines for users and providers of CDE environments to follow when using them. Even the BEP, which is otherwise a powerful tool for planning the specifics of a construction project, does not provide security guidelines.
For safe implementation of BIM and CDE cloud environments in construction projects, it is critical that all stakeholders are aware of the dangers that can result from inadequate security controls. A shared responsibility model should be included in the BEP guidelines, clearly stating which aspects of security must be ensured by both the provider and the user. Users must be aware of the security threats and select a suitable provider of a CDE environment also on the basis of security aspects. In the guidelines for users of CDE and BIM environments, we provide advice that can help users choose the right provider for their security requirements.
A transparent and confidential relationship between the provider and the user of BIM and CDE environments is central to the implementation of these environments. Providers must provide secure solutions, but there is an incentive for users to ensure that appropriate standards are maintained and security aspects are properly disclosed to users so that the services can be trusted.

THE INTEGRATION OF EARLY STAGE LIFE CYCLE ANALYSIS INTO ARCHITECTURAL PRACTICE THROUGH AN IT SUPPORTED PROCESS

Catherine Sinclair[1,2], Zaid Alwan[2]
[1]Space Architects, Newcastle Upon Tyne, UK
[2]Northumbria University, Newcastle Upon Tyne, UK

Abstract

Within the construction industry, a variety of tools undertake Life Cycle Analysis (LCA), including OneClick LCA, Tally and others recently developed. Early design decisions provide the biggest opportunity to reduce the whole life carbon (WLC) of a design. A mixed methodology approach including software appraisals, questionnaires and literature reviews found that current LCA tools do not encourage a free flowing design process and cannot analyse early stage decisions for their carbon impact. Integrating BIM and LCA at early design stages, reviewing decisions, using modern computing techniques and automated analysis is essential to addressing and reducing impacts through the construction phases.

Introduction

There is a growing base of evidence to suggest the impact of climate change is having an adverse effect on the natural and built environment. One example of addressing this is the UN adopting 17 sustainable development goals which were adopted by all United Nation Member States. These goals stated that ending poverty and other deprivations must work alongside improving health and education, reducing inequality and spurring economic growth, whilst tackling the threat of climate change (United Nations, 2015). Within the UK, the built environment is responsible for 25% of greenhouse gas emissions produced (Environmental Audit Committee, 2022). If the UK is to reach their Net Zero by 2050 goal, these figures need to be significantly reduced. Worldwide, the construction industry is currently responsible for 39% of energy related carbon emissions with 28% being from operational carbon and 11% being from embodied carbon (World Green Building Council, 2022). The construction industry has a vital part to play in addressing the climate emergency. Furthermore, the focus of WLC reduction within the construction industry is shifting from focussing on operational carbon reduction to reducing embodied carbon, this is due to the major improvements in the operational energy efficiency of the construction sector (Victoria and Perera, 2018). Operational carbon emissions are also more regulated than embodied carbon emissions with policies such as Approved Document L in the UK, which regulates operational carbon emissions. Currently there are no Government policies within the UK that require the assessment or control of embodied carbon emissions (Building to net zero: costing carbon in construction: Government Response to the Committee's First Report, 2022). Voluntary targets have been set in the UK by construction professionals for the reduction of embodied and operational carbon, this includes targets set by the Low Energy Transformation Initiative (LETI) and the Royal Institute of British Architects. LETI is a UK based network of built environment professionals that are collaboratively working towards a zero carbon future for both the planet and the UK (leti, n.d.).

The RIBA has developed the 2030 Climate Challenge, this sets a series of targets for Architectural practices to meet with the aim to reduce embodied and operational carbon (RIBA, 2019). LETI have also published a series of guidance documents to be used by construction professionals in order to reduce the WLC of the construction industry. Architects have a key role in reducing emissions within the construction industry, with consideration and analysis across all stages of the RIBA Plan of Work. Within the design process the key design decisions that affect both operational and embodied emissions cannot currently be automatically analysed and there is no automation within the design process. The software currently available, such as Autodesk Revit and Autocad, act as an essential tool within the design process but do not encourage the reduction of emissions. Low carbon design is essential within the construction industry in order to address the climate crisis.

The objective of this paper will be to evaluate the current processes and software used within the architectural design process and use for the calculation and reduction of WLC based on a large architectural practice in the north east of England. It will also be reviewed how embodied carbon is currently calculated within architectural practice and whether it is currently integrated within the process. Consideration will be taken regarding the perception Architects and designers have regarding embodied and operational carbon analysis across the RIBA plan of work. This will lead to discussions on how the process can be automated using IT in order to be integrated into architectural practice. In turn this will help draw conclusions on how to reduce embodied carbon within the construction industry through automation in design and integration of analysis.

The use of Building Information Modelling (BIM) within architectural practice is still developing. There are still barriers to the implementation of BIM in practice, these include lack of awareness, lack of training, training expenses and social resistance to change (Ahmed, 2018). Research has shown that the construction industry has been slow in adopting advancements and technological innovations that have enhanced workflow and productivity within other industries (Ojo and Pye, 2020). There are a variety of tools that are available that both support the utilisation of BIM and tools that incorporate LCA. These tools have not been widely implemented in practice or across the RIBA plan of work, creating a fragmented process. The RIBA plan of work organises the process of briefing, designing, constructing, maintain and operating into 8 stages (RIBA, 2024). The tools need to be seamlessly integrated into the RIBA plan of work allowing use across the lifecycle of a project. The current fragmented approach has not encouraged use of the tools during the design process where major design decision affecting embodied carbon are made.

Literature Review

Through studying relevant literature, from both academic and industry sources. The aim was to find out information regarding current software, current LCA tools, importance of early stage analysis, automation within design and the ability to interlink BIM and LCA.

Current Software and analysis tools

It is imperative that computational tools are utilised within architectural practice, both throughout the design process and for LCA. Within the construction industry there are a variety of tools that can conduct LCA of a design. These include but are not limited to Tally, One Click LCA, Eccolab, HBERT and FCBS Carbon. From this list, One Click LCA and Tally are the only tools that can be fully integrated into the BIM environment (Al-Ghamdi and Bilec, 2017). At the early design stages, these tools are not able to be utilised as there is not enough information within the design to undertake a LCA. The majority of tools that have been developed are designed for either post-construction evaluations or evaluations at the detail design stage, these tools are then used as part of scientific research as opposed to as a design tool (Meex et al., 2018).

LCA are currently a data intensive process, requiring a high level of information and computing ability by the user to calculate the embodied carbon of a design. LCA are currently used to give feedback as opposed to being able to be used as a tool to improve the design (Röck et al., 2018). Currently LCA's have not been widely adopted into architectural practice due to the complexity of analysis, the tools are very time consuming to use and there are challenges in gathering the required data (Kamari, Kotula and Schultz, 2022).

There is a high demand for a simplified approach to LCA that Architects can use within practice, and integrate into their current workflow. This will have to have an efficient and simple approach that does not require the detailed knowledge of LCA (Hollberg and Ruth, 2016). In order for LCA to be used and accepted into practice, the tools must be seamlessly integrated into the workflow and also become embedded in the culture of the practice (Means and Guggemos, 2015).

The Royal Institute of Chartered Surveyors (RICS) have released whole life carbon assessment (WLCA) for the built environment. This document will provide guidance and become the standard for consistent and accurate carbon measurement in the built environment (RICS, 2023). Previously, there was a need to standardise embodied carbon measurement as there was a huge variation in embodied carbon figures reported, which was attributed to the variability of the assumptions made in the measurements (Victoria and Perera, 2018). The results of assessments are still dependent on a series of factors such as system boundaries which are specified in BS EN 15978. The boundary choices can make a significant difference in embodied energy calculations (Dixit et al., 2010). Another variable could include choice of material library or data sources, within the UK that could include but is not limited to The Inventory of Carbon and Energy (ICE) and the Built Environment Carbon Database (BECD).

Building performance Assessment and automation within design

Worldwide there are a variety of building performance assessments including BREEAM, LEED, DGNB, Estidama and more. The schemes have some key differences which include the weighting that they give to different environmental categories. The weighting systems take into account climate and culture (BSRIA, 2011). These systems assist in creating goals and benchmarks and assist comparing alternative methods, however these methods are rarely incorporated at the early stages of design development (Häkkinen et al., 2015).

Currently there is no continuity throughout the RIBA stages in order to assess the WLC of a building (O'Sullivan et al., 2004). As it is a fragmented approach, current tools and systems have been described as too time consuming and complicated to effectively integrate into the design process. It was stated that it is important to develop the usability of the tools, integrating methods for WLCA into the design process, utilising a semi-automated tool (Häkkinen and Belloni, 2011).

As IT use within architectural practices is still growing, especially the use of BIM, design automation needs to be utilised. Design automation applications can show the environmental impact schemes can have, providing the opportunity to evaluate early design decisions against the WLC of a project. This can be done using a set of rules or parameters that evaluate the design (Gerth et al., 2016). Automation can also be utilised in order to reuse solutions that have been used on other projects, removing some of the routine work from the workflow of a project, allowing the designer to focus on other areas of the project (Gerth et al., 2016).

Digital tools provide the opportunity to decrease the additional work that is required to accurately undertake a life cycle assessment. Workflows have been developed to connect an LCA database such as the Inventory of Carbon and Energy (ICE) to a BIM software. For example there are cases where Dynamo for Autodesk Revit has been utilised (Hollberg, Genova and Habert, 2020). BIM and LCA have the potential to overcome the time consuming nature of undertaking a LCA, which will in turn facilitate the integration of environmental analysis, obtaining quick results about the impact of a building from an early design stage (Kamari, Kotula and Schultz, 2022). Soust-Verdauger et al. (2017) highlight significant challenges in the interoperability among the various applications, software integration of BIM and LCA and the amount of data that is required for LCA. It was also discussed that BIM-LCA integration will only be useful if the results and amount of data provided are user friendly (Soust-Verdaguer, Llatas and García-Martínez, 2017). These tools are able to be used when there is a high LOD in the design.

Early Stage Analysis

The majority of Architectural practices currently rely on in-house knowledge to make design decisions regarding WLC due to lack of access to specialist knowledge or simple design tools (Meex et al., 2018). Meex et al. (2018) also stated that in the earliest design stages Architects define the WLC of a building over its whole life cycle, often unknowingly, due to the lack of availability of analytical tools. Dunant et al stated that good early stage design decisions can halve embodied carbon (Dunant et al., 2021). To achieve this, it has been stated that designers have to have a greater understanding of which material and dimensioning decisions most significantly determine a building's environmental impact and which decisions are less important (Basbagill et al., 2013). It has been discussed that the building design process does not have the tools to analyse and consider WLC in the early stages of design. The most fundamental decisions which will affect the WLC of a building are conducted at an early stage. WLC reduction is not limited to material selection at an early stage design stage. It is widely discussed that a better form factor can make a huge difference in the reduction of embodied and operational carbon (make, 2021). Other considerations that should be analysed at an early design stage include window to wall ratio, orientation and structural grid spacings (Dunant et al., 2021). Basbagill et al. (2013) stated that considering shape and orientation during the early design stages, it is possible to reduce a designs environmental impact by 40%. According to Dunant et al. (2021), the typical building frame could have 40-60% less embodied carbon if a simple structural grid was chosen over a complex frame.

Window to wall ratio has a great impact on the operational energy of a building. Higher window to wall ratio is expected to be associated with increased heating energy due to more conductive loss through larger windows, but decreased lighting energy because bigger windows let in more daylight (Troup et al., 2019). An optimal window to wall ratio needs to be considered, this is one that minimises the sum of the energy use for heating, cooling and lighting (Goia, 2016). The optimum figure for different building typologies needs to be taken into account at early design stages. A building's orientation combined with its glazing ratio is key to minimising energy demand (LETI, 2020). LETI conducted a study that proved difference orientations of a building can almost double the space heating demand of a building (LETI, 2020).

Currently analysis is usually carried out after the detailed design stage has taken place. This is due to earlier stages of the BIM model having a low Level of Development (LOD), where generic building elements are used and accurate whole life carbon analysis cannot take place (Röck et al., 2018). Whilst analysis at a later stage gives more accurate data with the higher LOD, the ability to influence change is significantly lower. LCA should be able to take place at the earliest BIM LOD (LOD 100) in order to have the highest impact throughout the design. Changes to the developed design following later stage analysis will have larger cost implications than at an earlier stage, and the ability to influence change is lower (Gervásio et al., 2014). Gervásio et al. (2014) suggest an approach that involves a set of pre-defined construction components which incorporate embodied carbon impacts. This will provide the designer with the ability to compare options. Similar analysis is available within the H\B:ERT tool, an open source Revit tool that allows the designer to analyse building components (Hawkins Brown n.d.).

Methodology and Approach

Questionnaire

In order to gather data from a wide range of participants across a variety of stages of their careers in the field of Architecture, a questionnaire was undertaken. This included but was not limited to Architectural Technologists, Architects and Architectural Directors. Being able to gain information on the level of the participants career pinpointed the gaps in knowledge and skills within architectural practice. The questionnaire was systematically constructed following the process of the RIBA plan of work. It was structured to review strategies for assessing carbon impacts and gaps in knowledge/software across the RIBA plan of work. The questionnaire discusses levels of knowledge of WLC, analysis conducted within practice and software used at different RIBA stages.

Review of Current Software and workflow

There has been a variety of LCA tools, utilising different carbon databases. In order to gain an understanding of the opportunities and constraints of existing tools and software, a range of LCA tools will be reviewed. It will be considered how they will be able to be implemented into practice and into the workflow of a project.

Through the sources mentioned above, a workflow within practice will be identified. The workflow will be analysed and areas will be identified that would benefit from automation and LCA using IT within the design process. This will lead to a process or framework being developed that will assist in the reduction of embodied and operational carbon over the all stages of the RIBA plan of work, utilising appropriate tools.

Results

Questionnaire

The results of the questionnaire covered a wide spread of people across various stages of their career.

The results provided an insight of when the design process progressed from 2D on paper to 3D utilising Computer Aided Design (CAD). CAD was used from RIBA Stage 2, Concept Design. The main software used according to the participants was Autodesk Revit, which is a software that supports BIM management (breakwithanarchitect, 2018).

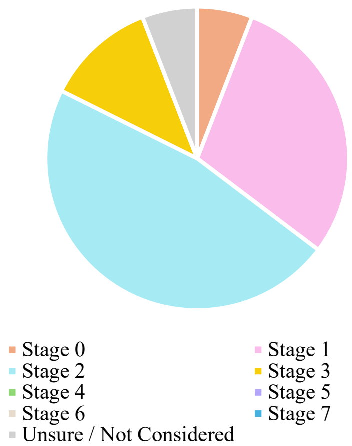

Figure 1: At what RIBA stage do you begin to use Revit

50% of participants thought that the key decisions regarding embodied carbon in a project were made at RIBA Stage 3 (Spatial Coordination). 22% stated that they considered the key decisions to be made at RIBA Stage 4 (Detailed Design).

Only one participant had conducted LCA on a project, with 78% never having conducted or outsourced an assessment. The one participant that had conducted LCA stated that they completed it at RIBA Stage 4 as it was a requirement of the project brief.

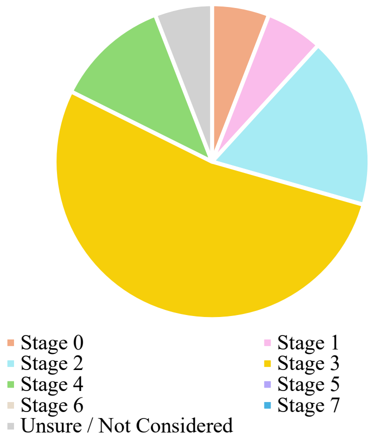

Figure 2: At what stage do you think the key decisions regarding embodied carbon are currently made on our projects

All of the participants stated that more guidance is needed within architectural practices to reduce embodied carbon at early design stages and throughout the project.

The most common response for lack of integration of embodied carbon analysis is the lack of knowledge and time. Alongside this there were comments about the lack of suitable software in order to automate the process. It was discussed that the more automated the process of analysis, the more likely it will be to be integrated into the design process. It was also commented that the main tools that are currently used do not produce live feedback and make reviewing design changes possible. Furthermore they are more mathematical as opposed to using design data, with a data heavy interface, making them unappealing to the design based users. They do not provide results that are easy to understand and are not visual.

Review of Current Software and workflow

A review of a range of tools and software was undertaken. The tools chosen are primarily aimed for use within Architectural practice, reducing the WLC of a project.

The first tool that was reviewed was OneClick LCA, this tool has the ability to extract information from a Revit model. This tool can only be utilised if the design is fully developed and the materials have been correctly set. Given the detail required, this will be used at RIBA Stage 4. It is also reliant on the Revit model being accurately and correctly modelled. Once the analysis has been conducted on the OneClick LCA web platform, it is necessary to manually check the analysis to confirm accuracy, this is a very time consuming process. OneClick LCA can compare a variety of EPD's, and states that it has the worlds largest construction LCA database (One Click LCA® software, n.d.).

FCBS Carbon is an excel based tool and requires all information to be manually input. The tool uses data from the Inventory of Carbon and Energy (ICE) and product EPD's (portal.fcbstudios.com, n.d.). The tool can be utilised at an earlier stage of design, but quantities and material choices are still required.

Within Architectural Practice, Computer Aided Design (CAD) is utilised from RIBA Stage 2. No evidence was gathered showing that embodied carbon was analysed at this stage, or further through the project. This was supported by the literature that the sector is resistance to new innovation technologies. Work by Alwan and Ilhan Jones, 2022 claimed that within the industry, one of the main barriers is the resistance to change from the traditional working practices alongside the time required to adapt to new innovative technologies.

Discussion

The results show on the whole that there is a requirement for both early stage LCA analysis and also simpler and more accessible design tools to be put in place to implement this throughout architectural practice. This is an important development to pursue, with the goal to reduce the environmental impact of the construction industry. This study has reinforced the need for development within architectural practice focussing on linking LCA and BIM. The literature has shown that not possible to conduct an accurate LCA at early design stages. Even though the current tools available cannot accurately measure WLC at early design stages, decisions can be made that affect the WLC of a project. Current literature shows that early stage design decisions can significantly reduce the WLC of a project. These early stage design decisions need to be analysed in order to set the design on the right trajectory to lower WLC. The comments received in the questionnaire also stated that more guidance is needed both with regard to design decisions and material choices.

The results of the questionnaire suggest that the key decisions regarding WLC are made at RIBA Stage 3. Existing literature suggests that these decisions are in fact made at RIBA Stage 2. As both sources state that the most important decisions regarding WLC are made in the early stages of the design process, it is evident that further tools and guidance is needed within the industry to assist in decision making. The early stage design decisions need to be analysed in order to provide guidance in low carbon design. The analysis needs to be undertaken as an automated process so that it can run hand in hand with the standard design process. This will encourage the new system to be widely adopted, especially if the process is neither complex or time consuming. Having design analysis from RIBA Stage 2 will assist in the reduction of WLC, before material selection takes place. The results discuss that key early design decisions effect the WLC of a project before material selection takes place.

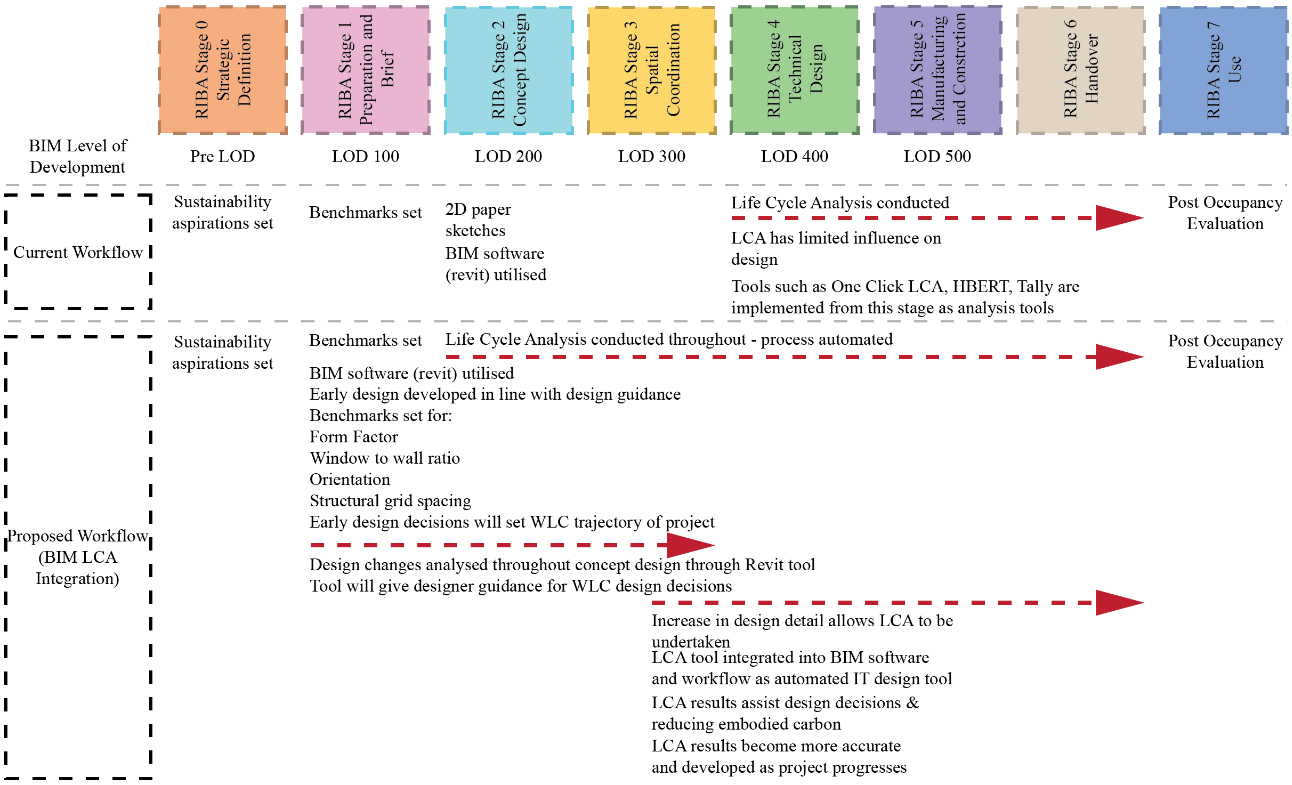

Figure 3: Existing and proposed workflow

With Revit being used from RIBA Stage 2, automation of analysis using IT tools within the design process would be able to be implemented from an early stage. Alongside this, using computer modelling from concept design stage should allow embodied carbon analysis to take place throughout the design process and through the RIBA work stages. Analysing the project from early stages will allow the design process to be influenced by constantly reviewing the information. Integrating analysis through an automated process at an early stage will assist in this decision making, increasing the ability to reduce embodied carbon from an early stage. With the industry being resistant to change from the traditional process, the tool will have to be simple to use and analyse the results, as well as not being a time consuming process.

Following analysis of both the questionnaire and existing software available it is obvious that there is a gap within Architectural Practice regarding automated LCA within the project workflow. The tools that are currently available either require a higher skill level than is available in practice or are time consuming to undertake. This is evident in the fact that only one participant had made use of a LCA tool within their projects. Furthermore, as the analysis was only conducted at RIBA Stage 4, we have to consider whether this had an impact on the final design, or whether the tool was used to only report the impact.

Conclusion

Analysis has confirmed that there is a gap in WLC design and analysis during the concept design stage or RIBA Stage 2. The tools currently available can analyse projects with a high LOD and the tools require a high skill level and are time consuming. Creating an IT based tool that is able to be utilised at an early concept design stage where we have the ability to have the biggest impact on the WLC of a project is necessary.

After reviewing relevant literature it is apparent that it is not possible to accurately undertake LCA at early stages of a design. The literature did provide an insight into the fact that early stage design decisions can have a large impact into the WLC of a project. These early stage decisions need to be analysed, this will provide guidance to the designer that the decisions made will set the project on the right trajectory to reduce the WLC. As the survey states, key decisions regarding WLC are made at RIBA 2 & 3, as this is where the major design decisions are made, setting the trajectory of the project.

A tool needs to be developed that can analyse early stage design decisions and provide the designer with feedback about the decisions they make. With the lack of detail at early stages, properties analysed will include form factor, window to wall ratio, structural grid and orientation. In line with the tool, a series of benchmarks need to be developed so that the designer understands the decisions that are being made. Following the analysis, it is not possible to conduct an accurate LCA at early design stages.

Following the feedback, this tool will have to be automated and take information from the model and provide the designer with a graphical representation of any carbon hotspots and room for improvement. The tool will have to be digitally integrated into the workflow of a construction project, giving design guidance throughout the process. This research shows that there is a need for future tools and gives the foundations for a future tool to be developed. The analytical process conducted within architectural practice shows the need for a design based tool that utilises IT tools that are integrated into the design and construction process.

In conclusion it is apparent that there is a gap in early stage analysis. Following this initial research a tool will be developed that can be utilised from RIBA Stage 2. The tool will assess early stage design decisions such as form factor, window to wall ratio, structural grid and orientation automatically through a Revit based plugin, assisting the designer in making decisions that will affect the WLC of a project before being able to conduct LCA.

This research is being developed as part of a two year Knowledge Transfer Partnership funded by Innovate UK and UK Research and Innovation. This research will continue to be developed as part of the Knowledge Transfer Partnership.

OPENBIM DIGITIZATION OF THE ITALIAN FIRE PREVENTION CODE: AN IMPLEMENTATION ON REACTION TO FIRE

Nicola Iraci Sareri, Carlo Zanchetta, Maria Grazia Donatiello and Andrea Zamborlini
Department of Civil, Environmental and Architectural Engineering, University of Padova, Padova, Italy

Abstract

The study explores the topic of digital transition applied to fire prevention. It investigates the potential of Industry Foundation Classes (IFC) implementation in Fire Safety Engineering. Literature review highlights that, at this moment, IFC classes and attributes related to fire prevention are limited and poorly defined. In particular, the study analyses the reaction to fire of building elements and develops an algorithm that automates the code checking process through an experimental application based on a simplified building model. The results prove that the IFC data model is promising for the Fire Prevention Code's digitization.

Introduction

In recent years, the AEC industry has undergone many changes due to the progressive implementation of Building Information Modeling (BIM). Globally, based on the ISO 19650 standard, the use of open formats has become mandatory to ensure interoperability among various actors and to protect data transmission throughout the building lifecycle. In this sense, ISO 16739 defines the Industry Foundation Classes (IFC) format as an international standard for information exchange within BIM processes. Despite the ambitions, the standard is not fully usable. To date, some engineering topics, such as energetics and its simulations, acoustics, fire protection or maintenance scheduling, are not yet fully manageable through the IFC standard. The main problem concerns the lack of a common international standard for engineering domains. Each country, having its own legislation, imposes different approaches that prevent a unified vision. This is notably typical in the field of fire prevention. An initial harmonization effort among European states concerns the reaction to fire of building materials. Many countries use Euro-classes to classify the reaction to fire of materials (Zaccarelli, 2020). Even Italy, while having its own system, has made mandatory for manufacturers to use products classified only according to the Euro-classes since October 2023.

To encourage digitization, in the 2020 the National Fire Service promoted the Fire Digital Check (FDC) project with the circular STAFFCNVVF prot. n. 18332, which aimed at the acceptance of the requirements of the Ministerial Decree 560/17. The final goal of this project is to automate the verification of the authorization process, thus reducing the time to verify projects compliancy, optimizing resources and at the same time ensuring greater control of projects, which results in high levels of safety and quality (Negri, 2022).

This initiative is aligned with the activity of the Regulatory Room of BuildingSMART, which points at the automation and digitization of building approvals (Moreno, 2020).

To achieve it, the FDC project identified three steps:

1. Digitization of the code: digitize and standardize the language for compiling a fire prevention project;
2. Project validation/verification: digitize and standardize the verification process of a fire prevention project to automate the check;
3. Performance management: digitize and standardize the performance management language for the entire life of the building also in terms of fire prevention.

Currently, only the first of the three steps outlined by the FDC has been analysed and lead to the creation of proprietary parameters (Lala et al., 2022). However, the work does not consider the actual development of the IFC standard; actually, proprietary parameters were created to describe information which was already available in IFC data model. This study, first, focuses on the reaction to fire to demonstrate the feasibility of digitizing the Italian Fire Prevention Code predominantly through the use of native IFC parameters; second, it wants to demonstrate how it is possible to pursue, the automation of project approval based on the ISO 16739 standard, in accordance with BuildingSMART's Regulatory Room and the principles behind the FDC project,. A small project was implemented with the identified parameters, and finally, using a Python script, it was possible to check the compliancy of the information model with the national standard.

Background

Italian Fire Prevention Code and reaction to fire

According to a study conducted by a European Commission of 34 countries, only 30 of them have a legislation based on a performance approach (Athanasopoulou et al., 2023). The change for most states came after 2015. In Italy, just in 2015, with the approval of the new Fire Prevention Code, there was a shift from a prescriptive approach to a performance based one.

This transition requires a technical understanding of fire safety principles, followed by the application of proven engineering methods and calculations (Puchovsky, 1996). Through a performance regulation, it is possible to identify, from the actual fire risk, a precise strategy targeted to the needs of the specific project.

The Italian Fire Prevention Code is divided into four parts, two of them were analyzed: sections G and S. In the first section, the risk profiles of activities and the methods for their determination are defined. In the second section, ten fire prevention measures applicable to all activities are described. The first measure is reaction to fire.

Reaction to fire expresses the "behaviour of a material that, with its decomposition, participates in a fire to which it has been subjected under specific conditions"(Ponziani, 2019). It is a passive measure of fire protection that effects the fire prevention strategy in the initial phase (pre-flashover phase). This measure delays the achievement of the flashover condition because it limits the ignition and participation of materials in combustion, preventing or delaying the spread of fire and smoke.

On a regulatory level, the degree of material participation is assigned through the determination of certain classes of reaction to fire. These must be assigned to all building materials and products, including coatings, insulation, mobile fittings, and curtains.

This performance specification is assigned by laboratory tests performed by technical reference standards, through which specific classes of reaction to fire are determined. In the Italian Fire Prevention Code minimum reaction to fire classifications are expressed, referring both to Italian and European classification systems. These are given for each performance level. From 2022 with Ministerial Decree No.251 of 14/10/2022, the use of Italian classes for the classification of reaction to fire of construction products is no longer allowed. These products become classifiable only with the European classes according to EN 13501-1.

The Italian reaction to fire classifications, indicated with [Ita], refer to the DM 26/06/1984 which identifies six classes: from class 0, relative to non-combustible materials, to class 5 with the increasing of the material's participation in combustion. These classes refer to furnishing materials and products, such as furniture, moquettes, curtains, blankets and parquet floors, but also to scenic elements and tent covers. The reaction to fire class for upholstered furniture (armchairs, sofas, mattresses, upholstered chairs) are 1IM, 2IM, 3IM, this increases as the fire participation rate increases. The reaction to fire class assigned must refer to the whole composition of the covering, the upholstery and any interposed element.

European reaction to fire classes is only assigned to products compliant to Regulation 305/2011/EU concerning construction products, with reference to DM 10/3/2005. In Code's tables, they are indicated with the abbreviation [EU]. According to the EN 13501-1: 2018, the European classification is carried out by an alphanumeric code made up of the combination of main classes (A1, A2, B, C, D, E, F) with complementary classes relating to smoke production (s1, s2, s3), flaming droplets (d0, d1, d2) and acid smoke production (a1, a2, a3).

Table 1: Additional classification for smoke production

Acronym	Description
s3	No limitation of smoke production required
s2	The total smoke production as well as the ratio of increase in smoke production are limited
s1	More stringent criteria than s2 are satisfied

Table 2: Additional classification for flaming droplets

Acronym	Description
d2	No limitation
d1	No flaming droplets/particles persisting longer than a given time occurred
d0	No flaming droplets/particles occurred

Products that, although not intrinsically hazardous, have not yet been classified (Sabatino et al., 2021) belong to class F. Moreover, subscript abbreviations are sometimes added to the main classes in the following cases:

- fl in the case of floor products;
- L in the case of linear thermal insulation;
- ca in the case of electrical cables.

The compliance check of materials' behaviour in terms of reaction to fire depends on the performance levels assigned. Thus, it is necessary to establish the performance levels for each area of the activity through the attribution criteria. These are indicative and in the case of reaction to fire, a distinction is made between an escape route and a room. This distinction is necessary because of the importance of escape routes in saving lives, which require a more demanding performance. Consequently, the accepted performance level for rooms is generally immediately lower than the one indicated for escape routes of the corresponding risk profile.

As shown in Table 3, four performance levels were identified, each with its own description in qualitative terms. It emerges that only those spaces falling within performance levels II, III and IV are those in which the participation of materials in combustion is to be limited (Dattilo & Cavriani, 2019).

Table 3: Reaction to fire's performance levels

Performance level	Description
I	The contribution of materials to the fire is not assessed
II	The contribution of materials to the fire is significant
III	The contribution of materials to the fire is moderate
IV	The contribution of materials to the fire is almost negligible

For each performance level there is a corresponding compliant solution which consists of the use of materials belonging to certain groups (GM) identified by a number varying from 0 to 4 as their contribution to the fire increases.

The GM0 materials group does not make any contribution to fire and consist of all those materials with Italian reaction to fire class 0 or European reaction to fire class A1. It includes all the, so-called, incombustible materials. Materials group GM4, on the other hand, consist of all the ones that are not included in groups GM0, GM1, GM2, GM3. Thus, it includes unclassified materials and class F construction products. Since there is no requirement at the first performance level, compliant solutions are only defined for performance levels II, III and IV as shown in Table 4.

Table 4: Compliant solutions for each performance level

Performance level	Compliant solutions
I	No requirement
II	GM3
III	GM2
IV	GM1

The reaction to fire classes of materials included in materials groups GM1, GM2, GM3 are specified from table S.1-5 to table S.1-8 of the Italian Fire Prevention Code.

Reliability of IFC data model to support BIM based Fire Safety code checking

IFC is an international standard, organized into hierarchical classes through which the building system can be described. IFC should describe all aspects of all engineering disciplines through entity, types and relationships.

All subjects, from different disciplines, can use the IFC standard to exchange information. To ensure fast and lightweight exchange, IFC can be filtered with reference to the Model View Definitions (MVD). BuildingSMART has created many official MVDs. Currently, a sponsor search is underway to build a new MVD dedicated to FireSafety Engineering. The main limitation always concerns the lack of single legislation, in fact this new MVD is a consequence of a proposal of the International Fire Safety Standards (IFSS) Coalition. To reach "the first agreement on fire safety actions on an international scale", the consortium agreed to a 10-year commitment until 2032 (buildingSMART International, 2022). Without the IFC standard the exchange of information between the various subjects would be much longer and complicated because the various software would have to find a way to talk to each other, instead by using the IFC standard all software would be able to speak the same language (Laakso & Student, 2012). To ensure a future in the AEC industry based on interoperability among various players, BuildingSMART continues to rework and improve the IFC standard. With the roadmap developed in 2020, the organization wanted to emphasize how the future of the construction industry must move away from adopting solutions that do not work "out of the box" and embrace generic solutions (buildingSMART, 2020).

However, the use of IFC encounters difficulties related to incorrect use by actors and inappropriate reading and writing by some software. In the field of fire prevention, the prime example of a lack of standardized communication between different software is with fire dynamic simulation (FDS). To be able to simulate the fire, inside the building, simulation software first needs geometric information. Although within the IFC data model the geometric and spatial structure is well defined many studies have shown that it is not so easy for dynamic simulation software to receive information from the standard (Dimyadi et al., 2008) (Shi et al., 2019). Most software can only read CAD and DXF format so all relational information cannot be exported and read, or software only processes a limited set of data from IFC, sufficient to obtain basic building geometry and properties (Spearpoint & Dimyadi, 2007). Another research (Siddiqui et al., 2021) highlights the difficulty of operators in exchanging performance information. Most fire and evacuation modelling tools do not export results via open formats, while those that are able to do so, limit the export to geometric data, and not to the information that must be provided. The most obvious problem relates to the gaps that IFC has in relation to fire prevention regulations.

Previous research (Zanchetta et al., 2023) highlights precisely the limitations of the IFC data model with reference to some aspects of fire prevention. This research shows how to include information related to fire resistance, compartmentalization, and evacuation; it also introduces the discussion related to the reaction to fire of the materials highlighting how a unified reference is lacking. This lack leads different parties to freely create proprietary parameters, although they are already available in the standard, clashing with the concept of interoperability. One draft project, developed by a team related to the Italian Fire Digital Check project followed this second approach. Although the IFC standard was analysed, the team merely transcribed the Fire Prevention Code through a set of proprietary parameters. Regarding the reaction to fire class, the research team created a proprietary PropertySet named "VVF_Reazione al fuoco" within which there is the property to express the fire reaction class "Classe di reazione al fuoco".

BIM and automated code checking

Regulatory check is one of the aspects most prone to human error, so in recent years there has been an increasing interest toward automation. Automated rule checking (Eastman et al., 2009) consists of verifying that the project meets certain requirements. Rules should have the outcome “passed”, “failed”, “warning”, and it can be structured into four stages: (1) rule interpretation and logical structuring of rules for their application; (2) building model preparation, where the necessary information required for checking is prepared; (3) the rule execution phase, which carries out the checking, and (4) the reporting of the checking results.

There are several approaches available in literature related to automated rule checking. These are divided into systems known as “black box” and “white box” (Nidhra, 2012). The first ones involve the use of specific software generally difficult to implement and built through hard coding, while the second ones are transparent and involve the use of programming with codes or through visual programming tools (Ghannad et al., 2019). The latter approach is widely used mainly for the easy accessibility.

The software-based code is proving to be a popular choice for public administrations, which are thus able to combine a simplification of project approval work and with a potential saving of time and costs (Eastman et al., 2009). The most famous project is undoubtedly Singapore's CORENET (COnstruction and Real Estate NETwork), founded by the Minister of National Development (available at https://www.corenet.gov.sg/general/e-info.aspx). This project consists of three modules: CORENET e-Submission, CORENET e-PlanCheck and CORENET e-Info. With the e-PlanCheck module and FORENAX, it is possible to conduct a code check that includes different standards including those related to the fire Code (Greenwood et al., 2010). This project is a technology initiative that aimed to bring Singapore to the full integration of the phases of a building's lifecycle using IFC building model data.

This project was emulated in Norway with ByggSok project. The pilot project HITOS was checked with Solibri Model Checker (SMC) an IFC based commercial solution used for code checking. This software reads IFC model and is based on the Norwegian Stats'bugg handbook.

SMC and CORENET like many other applications, however, are “black box” because they present a set of rules that can be modified by the user and adapted to the specific project. On behalf they do not maintain the same freedom in creating new rules; the user must work on the product API to create them, which, however, are not public but only the developers themselves have access to them. (Simone et al., 2017).

Another approach to code checking is offered by visual programming solutions, which referring plug-ins such as Dynamo for Revit and Grasshopper for Rhino that support visual programming. A method, based on Dynamo, combines a semantic translation of the Malaysian fire safety regulations and the corresponding properties in Revit (Ismail et al., 2023). The regulations phrases are marked-up with four types of markers, using two of them (“requirements” and “exceptions”) to identify the necessary parameters in Revit. Eight scripts in Dynamo are created to check the compliance of the BIM modelled elements with the regulation’s provisions. Although this approach is very interesting, especially for the semantic translation implemented on regulatory aspects, it is a method focused on Revit's proprietary format and Dynamo, leaving no room for implementations in open formats.

Visual programming offers ease of programming and access to information, but it is based on solutions tied to proprietary formats as opposed to solutions implemented through scripts in python or java, which offer a wide range of completely open-source tools. IfcOpenShell is a python module which allows access to the elements contained in an IFC file and their properties, and its use is widespread because of its ease in extracting, manipulating, and creating information in an IFC data model. Several examples showing the potential of IfcOpenShell and its ability to extract information are available in literature (Narinder Singh et al., 2020; Singh et al., 2022). An interesting example of this Python module is used in an automated implementation of escape route information in IFC files (Haselberger, 2023).

The last relevant approach to code checking lies in the semantic web and graph databases. An interesting example (Peng & Liu, 2023) proposes an automatic code compliance checking based on BIM and Web technology. This study added the technique of knowledge graph to the structured processing of the rules. Its power lies in the application of natural language processing techniques to transform requirements into checking rules in the form of knowledge graphs.

Experimentation

In this section, it is illustrated the experimentation concerning the digitization of the reaction to fire measure. The purpose of this experimentation is to demonstrate that it is possible, through painstaking research, analysis, and definition, to achieve the objectives of the Fire Digital Check using exclusively ISO 16739. This turns out to be much more correct for the collaboration, interoperability and knowledge reuse because it does not consider parameters defined arbitrarily but relies on parameters already defined within an international and recognized standard, embracing the OpenBIM methodology. The following sub-sections explain the conceptual workflow and the translation in OpenBIM protocols.

Model construction

To test the experimental application, it was decided to consider a prototype nursing home. Therefore, the risk profile concerning human life safety (R_{life}), determined by the prevailing characteristics of the occupants, would be either D1 or D2. This assumption will then be used to determine the performance levels to be associated to the spaces. The digital model was developed using Autodesk's Revit. The modelled building, rectangular in shape, consists of two floors above ground, identically spaced. Each of the two floors, connected by a stairwell, consists of three rooms of equal size and a hallway (Figure 1, Figure 2, Figure 3).

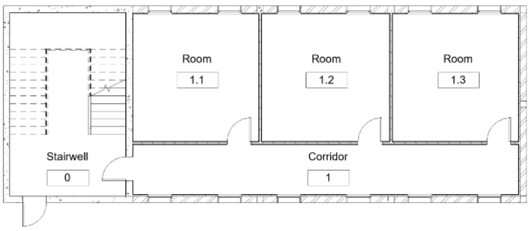

Figure 1: First-floor rooms

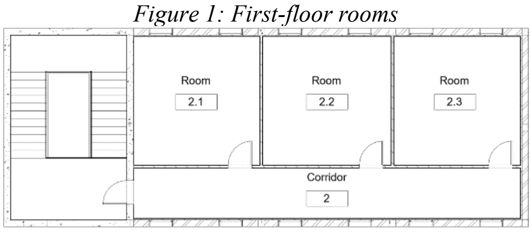

Figure 2: Second-floor rooms

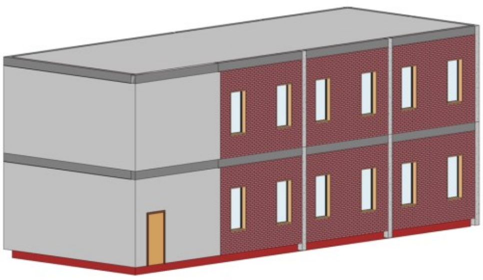

Figure 3: Building's Revit model

Check procedure

Before proceeding with the experiments, a verification procedure was devised. Starting with a room, which defines the required performance level, it is possible to identify all the boundary elements and, for each of them, check if their reaction to fire classes is compliant or not.

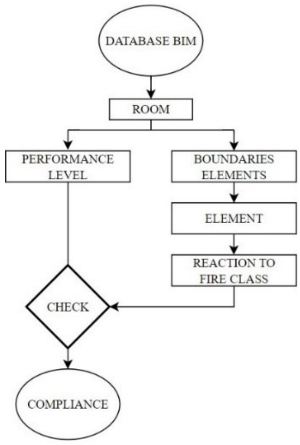

Figure 4: The assumed check procedure

Analysis of IFC attributes

For the study, the IFC version used is 4.3.2.0, made official in January 2024 (buildingSMART International, 2024).

Before compiling in the model the reaction to fire properties, it was necessary to understand where the information had to be placed according to IFC.

Reaction to fire is essentially a material property. In IFC materials are described through the class *IfcMaterial*. This entity is part of the resource domain, so it is just used to describe objects, it cannot have an instance of its own but must be related through *IfcRelAssociatesMaterial* to an entity of a higher layer. The entities in the resource layer do not have a unique identifier (Laakso & Student, 2012). For this reason, to clearly identify the uncompliant elements of the building, the reaction to fire property must be related to an object itself and not be attributed trough the material. This property can be attributed to objects such as walls, covering, roofs, siding, floors. Entities hierarchically lower than *IfcBuiltElement* and their properties were analysed. Specifically, the *IfcWall*, *IfcCovering*, *IfcSlab* and *IfcRoof* entities were analysed.

Regarding the reaction to fire performance of the elements, it was seen that *IfcWall*, *IfcSlab*, *IfcCovering* have two interesting properties: *Combustible* and *SurfaceSpreadOfFlame.* As highlighted in the previous research (Zanchetta et al., 2023) *IfcCovering* has a further possible property: *FlammabilityRating*. *IfcRoof*, instead, has none of these properties, as shown in Table 5.

Table 5: Entities of the IFC data model and the highlighted properties

	Property		
	FlammabilityRating	SurfaceSpreadOfFlame	Combustible
IfcCovering	✓	✓	✓
IfcRoof			
IfcSlab		✓	✓
IfcWall		✓	✓

Firstly, the properties *FlammabilityRating* and *SurfaceSpreadOfFlame* can be filled in with a string of text or numbers up to a maximum of 255 characters, while the property *Combustible* can assume a boolean value. The boolean value TRUE indicates that the object is made up of combustible material. If only this property is compiled, it could be assumed whether the material is combustible or not and thus whether it belongs to the GM0 material group (European class A1 and Italian class 0). However, this information is not relevant for the purpose of this research, because it does not provide any information about the specific reaction to fire class of the material and is therefore not useful for automatic verification of regulatory compliance. To best specify the fire behaviour of a material, it is necessary to assign to it a specific reaction to fire class, so the study proposes the inclusion of the specific class within the property.

FlammabilityRating and *SurfaceSpreadOfFlame* are very similar to each other (Table 6). The first one refers to the flammability of materials and the second to the way flames spread on the surface. The *SurfaceSpreadOfFlame* property seems to refer to the British standard, BS 476: Part 7: 1997, which defines a test method to measure lateral flame spread along wall and ceiling surfaces. The standard identifies four classes, from 1 to 4, of which Class 1 is the best in terms of flame propagation. However, this test doesn't specify the combustibility of a material. Instead, the European system based on Euroclasses (*EN 13501-1*, 2018), introduced in 2000 to eliminate trade barriers between member states and ensure consistent quality levels, refers to the reaction to fire of materials by considering not only the spread of flames but also many aspects, such as combustibility, the rate of participation in the fire and the ability to produce smoke. For this reason, the UK is still going through a transitional period in which it is still possible to find references to the national standard rather than the mandatory harmonized European classification, sometimes causing confusion about the performance of a given material as the two classifications refer to different aspects.

Table 6: IFC properties of interest

Property	Description
Flammability Rating	Flammability Rating for this object. It is given according to the national building code that governs the rating of flammability for materials
SurfaceSpread OfFlame	Indication on how the flames spread around the surface. It is given according to the national building code that governs the fire behaviour for materials
Combustible	Indication whether the object is made from combustible material (TRUE) or not (FALSE)

At the level of definition, it would be more correct to use the *FlammabilityRating* property because the concept of reaction to fire does not only refer to how the flame spreads on the wall, at the same time, this property it is attributable only to covering (*IfcCovering*). When the designer evaluates the reaction to fire of a wall, he must consider the whole stratigraphy not only the outermost layer although this one is more significant. So, it was decided to use the property *SurfaceSpreadOfFlame*. For the code checking, the reaction to fire within a space must be verified. The *IfcSpace* properties were analysed. As shown in Table 7, within the PropertySet *Pset_Risk*, there are four useful properties: *RiskType, RiskAssesmentMethodology, NatureOfRisk* and *RiskName*. The risk type Fire_Explosion was selected within the *RiskType* property, the regulatory reference (Fire Prevention Code) within the *RiskAssessmentMethodology* property, and the fire measure (reaction to fire) within the *NatureOfRisk* property. Finally, the performance level required for the fire reaction measure was associated with the *RiskName* property.

Table 7: IfcSpace Pset_Risk's properties

Property	Description
RiskType	Identifies the predefined types of risk from which the type required may be set
RiskAssessment Methodology	An indication or link to the chosen risk assessment methodology
NatureOfRisk	A description of the generic nature of the context or hazard that might be encountered
RiskName	A locally unique identifier for the risk entry that can be used to track the development and mitigation of the risk throughout the project life cycle

Selection of performance levels

Based on the use of the building, the model was implemented with the performance levels assumed within the *RiskName* property attributed to all rooms. According to the Fire Prevention Code, rooms and escape routes have different performance levels. Performance level 3 was assigned to rooms while performance level 4 (highest) was assigned to escape routes.

<Settings>

A	B	C	D	E	F
Type of room	Room number	Pset_Risk.RiskType	Pset_Risk.RiskAssessmentMethodology	Pset_Risk.NatureOfRisk	Pset_Risk.RiskName
Room	1.1	FIRE_EXPLOSION	D.M. 3/8/2015 e s.m.i.	Reaction to fire	3
Room	1.2	FIRE_EXPLOSION	D.M. 3/8/2015 e s.m.i.	Reaction to fire	3
Room	1.3	FIRE_EXPLOSION	D.M. 3/8/2015 e s.m.i.	Reaction to fire	3
Corridor	1	FIRE_EXPLOSION	D.M. 3/8/2015 e s.m.i.	Reaction to fire	4
Stairwell	0	FIRE_EXPLOSION	D.M. 3/8/2015 e s.m.i.	Reaction to fire	4

Corridor	2	FIRE_EXPLOSION	D.M. 3/8/2015 e s.m.i.	Reaction to fire	4

Figure 5: Properties of each room and evacuation route

Material selection

Various commercial materials were analysed and some with different reaction to fire classes were identified. A material with a reaction to fire class higher than the regulatory minimum was assigned to all walls except for one wall in rooms 1.1 on the first floor and 2.1 on the second one (Figure 6). For these two, wallpaper with a reaction to fire class lower than the regulatory minimum was installed. This distinction was necessary to validate the model-checking algorithm.

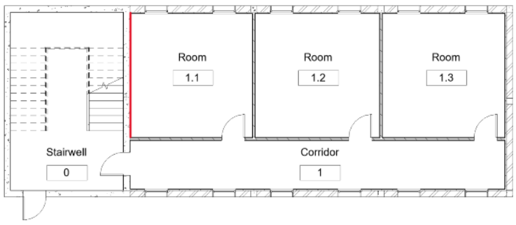

Figure 6: The wall where non-compliant wallpaper has been applied is highlighted in red. The same for the second floor

Algorithm development

The code checking algorithm was developed in open code using the Python programming language. Thanks to the IfcOpenShell library, it is possible to search all entities hierarchically below the IfcBuiltElement class previously identified properties for reaction to fire. This made it possible to implement computationally based compliance check. The script searches for every *IfcSpace* in the project the *IfcSpaceBoundaries* which enclose the room. The *IfcSpace* present the *Pset_Risk* which contains the *RiskName* property that express the reaction to fire's performance level. The algorithm reads the *RiskName* and compares the *SurfaceSpreadOfFlame* of each building element enclosing the *IfcSpace*.

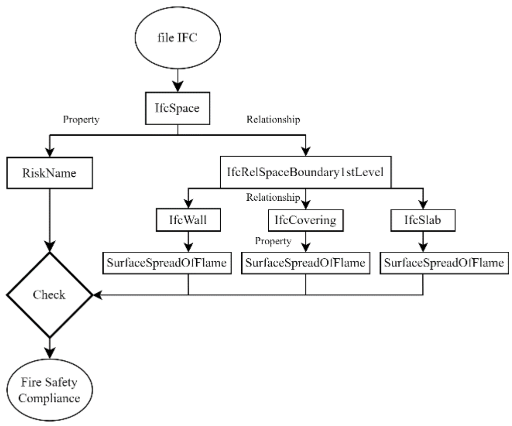

Figure 7: Script procedure

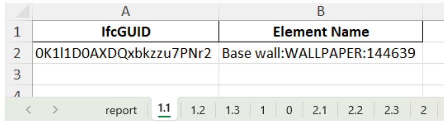
Results analysis

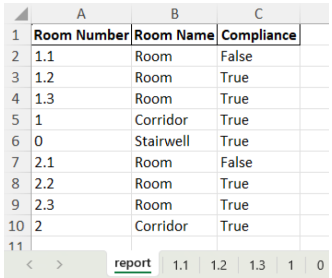
The algorithm was also set up to write an Excel file made up of several sheets, one for each room of the building, and one reporting every room and its compliance, which automatically is filled with True or False values. In the case of non-conforming elements, the global unique identifier (IfcGUID) and the name of the modelled element are reported. As can be seen from the Excel spreadsheets obtained, the only elements reported were the wallpapers installed in rooms1.1 and 2.1.

The algorithm was able to read all the boundary elements of each room, and to compare the values of the materials groups with the minimum values required by the performance level, thus automating the entire check. This approach, extended to all the other prescriptions contained in the Italian Fire Prevention Code could be the base of an automatic digital permitting, aligned with the BuildingSMART Regulatory Room's principles.



IfcGUID	Element Name
0K1l1D0AXDQxbkzzu7PNr2	Base wall:WALLPAPER:144639

Figure 8: Excel results



Room Number	Room Name	Compliance
1.1	Room	False
1.2	Room	True
1.3	Room	True
1	Corridor	True
0	Stairwell	True
2.1	Room	False
2.2	Room	True
2.3	Room	True
2	Corridor	True

Figure 9: Rooms' compliance report

Conclusions

In conclusion, the results give evidence of the high performance of the IFC format from the point of view of storing information, although they underline the difficulty of translating standards according to the logic of the IFC data format.

The study shows that, as a result of the normative translation, activities and analysis of the attributes and properties available in IFC, it is possible to use the properties already present within the IFC standard without creating new properties and to proceed to automatic code checking through the development of open algorithms. However, to achieve these results, it is necessary to have a detailed knowledge of the IFC architecture. Understanding which property to use was the biggest challenge because the definitions are not clear. Therefore, there is a need for BuildingSMART to comply with the standardization adopted by the different countries and to define a clear parameter within which the reaction-to-fire class can be entered, according to the Euroclasses. This research paves the way for many future developments, including refining what has been done about reaction to fire, digitization of other fire measures, and the mapping of regulatory requirements not currently covered by the IFC standard. The goal is the creation of an interoperable BIM database that serves both National Fire Service and fire prevention designers. The creation of an interoperable BIM database can be useful during design and verification for the issuance of the Fire Prevention Certificate.

LEVERAGING DIGITAL TWINS TOWARDS AN OCCUPANT-CENTRIC BUILT ENVIRONMENT: A REVIEW

Eduardo Navarro-Bringas [1]
[1]Heriot-Watt University, Edinburgh, UK

Abstract

One of the main purposes of building design and development is to enhance the experiences and activities of occupants. Traditionally, the longitudinal collection of occupant data has presented challenges. In this context, the emerging paradigm of Digital Twins (DTs) offers a promising solution. This systematic review investigates recent advancements in DT applications within the Architecture, Engineering, Construction and Operations (AECO) sector, focused on the integration and utilisation of real-time occupant data. Our findings categorize the types of data collected and the varying degrees of occupant involvement in these processes. The review also identifies the primary challenges encountered in data collection and integration, emphasising the need for balancing ethical and privacy concerns. Additionally, the paper explores the potential of DTs in enriching occupant-centric applications, highlighting their role in optimising building performance, enhancing comfort, and improving maintenance and safety. This review not only sheds light on the current state of occupant data in DT applications but also explores opportunities for leveraging occupant data to create more responsive and efficient built environments.

Introduction

The fundamental purpose of the built environment is to support and structure the activities and tasks of its occupants. Historically, understanding the impact of buildings on occupants has predominantly been the domain of Post-Occupancy Evaluations (POE). Initiated in the 1960s and 1970s, POEs have aimed to optimise and fine-tune building performance to better support occupants and inform the design of future structures (Preiser and Nasar, 2008). This field later expanded to include energy performance evaluations, significantly influenced by research in the 1990s and early 2000s (Leaman and Bordass, 2001). Despite significant contributions of POE to our current understanding of occupant comfort and general building performance, data collected from users has usually been limited to qualitative studies (i.e. focus groups) and one-off satisfaction surveys. As such, legacy challenges like the performance gap, the discrepancy between designed performance and actual performance persist, largely driven by occupant behaviour and usage patterns (Far *et al.,* 2022).

In recent years, the concept of Digital Twins (DTs) has emerged as a novel paradigm in built environment research. Evolving from advancements in Building Information Modelling (BIM), smart building technologies, and developments on Internet of Things (IoT) sensors, DTs offer the potential to enhance building performance through real-time data collection, granular control of building systems, and advanced operational intelligence via automation and improved simulation methods (Building Smart International, 2020). If the objective remains to design buildings that meet user needs, the role of DTs in understanding and refining performance for occupants could be substantial.

Although several systematic reviews have investigated DT applications in the built environment within recent years (Long *et al*., 2024), there has been limited focus on the specific challenges and opportunities related to integrating occupant data into DTs. This paper aims to examine how recent published research has addressed the incorporation of occupant data. Thus, the paper aims to analyse the selected articles to determine the purposes for which the identified DT applications are being developed, as well as to identify the various methods and types of occupant data that are integrated in the identified DTs.

Defining DTs

While the concept of Digital Twins (DTs) originated decades ago, primarily in the manufacturing context (Tao *et al*., 2019), its evolution in the built environment has been significantly influenced by advancements in smart buildings, the Internet of Things (IoT), enhanced sensing technologies, and the development of semantically rich digital models within Building Information Modelling (BIM). Additionally, recent reviews (Long *et al*., 2024) have shown an exponential growth in interest regarding DT applications in built environment research. Studies such as Shahzad *et al*. (2022) have highlighted a lack of common understanding among various stakeholders in the AECO sector, leading to challenges in establishing a universally accepted definition of a DT. For the purposes of this paper, a DT is defined as "(…) *a digital representation of a physical asset. Linked to each other, the physical and digital twin regularly exchange data* *throughout the Plan Build Operate Decommission lifecycle and use phase. Technologies like AI, machine learning (ML), sensors, and IoT allow for dynamic data gathering and right-time data exchange to take place*" (Building Smart International, 2020 p.2).

This definition encompasses the widely accepted view of DTs as digital replicas of physical assets, further enriched with data collected in real-time. However, to ensure consistent criteria for the article inclusion criteria used in this review, the constituents of a DT will be further defined. Drawing from the manufacturing sector, particularly the work of Tao *et al*. (2019) five layers have been identified as integral to a DT. Massafra *et al*. (2023) adapted these elements to the context of building-related DTs (Figure 1). These five constituents or layers include:

- Physical Asset: The building, equipped with IoT sensors.
- Virtual Asset: A digital representation of the building, typically a semantically rich Asset Information Model (AIM).
- Connections: The information and flows and connections that link the virtual and physical layers, as well as the other layers.
- Data: Integration of all data collected from both digital and physical asset layers to create a comprehensive and accurate information set.
- Services/Actuator: These facilitate the application of data to meet the needs of DT users. For instance, visualisation, system control, "*what-if*" scenario simulations etc.

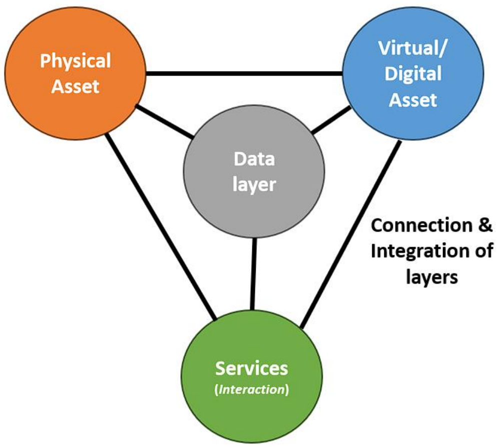

Figure 1. DT layers. Adapted from Massafra et al. (2023)

Methodology

Systematic Literature Review

This paper deploys a Systematic Literature Review (SLR) approach to establish the current state of occupant-centric DT applications within buildings. SLR was considered as a suitable approach, as the method allows for a systematic approach to collate exiting literature. Moreover, the method enables further understanding, synthesis of evidence, and identification of research gaps (Kitchenham, 2004). Additionally, the systematic approach to selection of papers enables for an unbiased approach to collating and reviewing the literature. This method is particularly valuable in uncovering themes and research directions within evolving fields, such as the integration of occupant data within DT applications. The following section will present protocol used for the SLR, as well as establish the criteria for selection of resources included in the SLR.

SLR procedure

The SLR commenced with the selection of Scopus as the primary database for literature search. Scopus was chosen over alternatives like Google Scholar due to its rigorous and well-curated nature, ensuring access to scholarly and peer-reviewed content. This decision aligns with the practices of previous SLRs in related fields, thereby upholding academic rigor and relevance. The process used to select the articles for inclusion in this review is presented in Figure 2.

The initial search, conducted on the 5th of January, utilised parameters such as "*Digital Twins*" AND "*Built Environment*" OR "*Building*" AND "*Occupant*" OR "*End user*" OR "*Post Occupancy Evaluation*". To filter these initial results, criteria were set to include sources from peer-reviewed journal articles in English language, which narrowed the initial query in Scopus to 40 articles.

Further screening involved a manual analysis of these papers by the research team. In this step, articles were excluded from the review if they did not meet the following criteria:

- Articles not focused on buildings as the unit of analysis. Through this criteria papers excluded for instance articles focused on a system of systems level, such as cities.
- Papers that did not met the previously established characteristics of a DT established in the introductory section of this paper were also omitted. These excluded papers that lacked a data layer combining real and virtual asset information.

The final sample (Table 1) of articles included in the revision included 20 articles.

SLR Results

Initial results showcase that the most common journal where occupant-centric DT research is being featured is *Building & Environment* (n=5), followed by *Energy & Buildings* (n=3), and *Sustainable Cities & Society*, *Applied Sciences* and *Buildings* with (n=2). These journals feature articles with a focus on Indoor Environmental Quality (IEQ) and energy issues within the

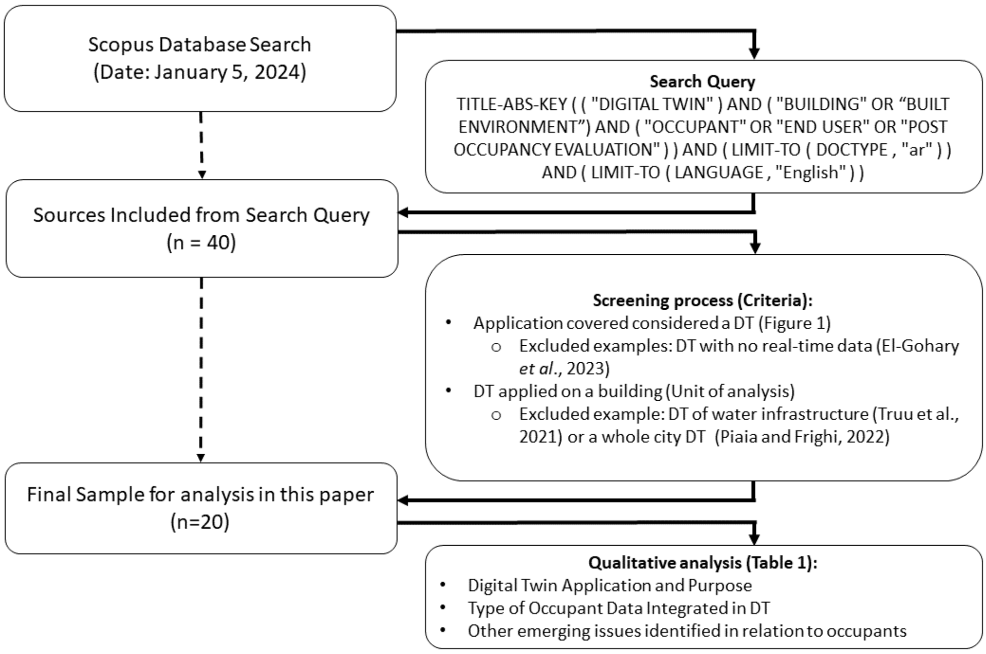

Figure 2. SLR procedure followed for the selection of the final 20 articles reviewed.

built environment. In terms of the country of affiliation of the first author, the country with the most extensive DT applications exploring occupancy issues is China with links to 4 of the reviewed studies. This is followed by 3 applications from Singapore and Italy. The remaining of the research appears quite widespread across a range of different countries, with Norway and Canada having multiple applications in the reviewed sample (n=2). Regarding publication year, the earliest article addressing

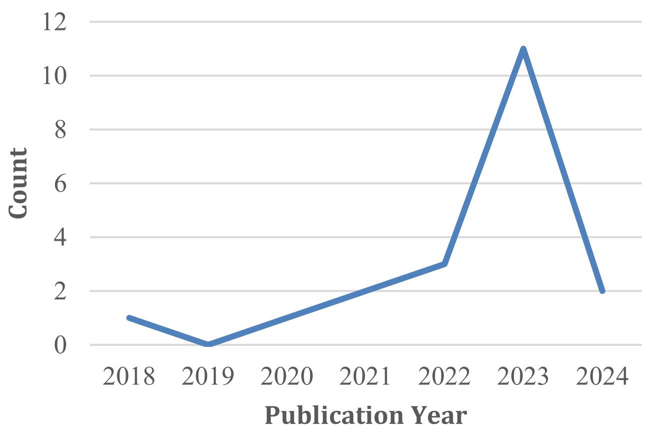

Figure 3 Publications per year (Up to 05/01/2024)

occupant data in building DTs included in the final review was published in 2018. The publication curve (figure 3) showcases an exponential growth in publications where the last 3 years (i.e. 2021-2023) have shown an increase in published articles in this area, with 55% (n=11) of the papers having been published in 2023. Table 1 presents a summary of the articles included in the final review.

Findings and themes from the SLR

Applications of occupant-centric DTs

Purpose 1: Systems & energy efficiency optimisation

One of the main applications identified refers to energy optimisation during the operation of buildings. In most cases, energy optimisation focuses on heating and cooling-related savings—i.e. mostly on the optimised use of Heating, Ventilation and Air Conditioning (HVAC) systems (Clausen *et al.*, 2021; Hosamo *et al.*, 2023b; Massafra *et al.*, 2023; Desogus *et al.*, 2023; Li *et al.*, 2023). Noticeably, the DT application presented in Seo and Yun's research (2022) places a strong focus on optimising energy consumed by lighting systems using schedules and simplified probability based behavioural models of occupants.

Regarding energy optimisation, the integration of occupant data into the DTs is expected to provide clearer insights into building operations for Facilities Management (FM). With some of the reviewed studies (Clausen *et al.*, 2021) aiming to establish an automated zone-based control that optimises the use and energy consumption from buildings. or allowing for the automation of building systems to optimise performance.

Purpose 2: Support of occupant comfort

The second purpose, while closely related to the previous, aims to develop DT applications that can better optimise the IEQ conditions to the occupants of the building. This application, often goes hand in hand with the previously discussed energy focus, presenting the DT as the key enabler of system performance improvements without the need to sacrifice occupant comfort.

Table 1. Articles included in SLR for review (n=20)

Seo & Yun (2022)	South Korea	Buildings	Energy savings through optimisation of lighting systems	Passive: Behaviour modelled on schedule data; no real-time data
Tripathi *et al.* (2023)	Canada	Frontiers in Built Environment	Understanding occupant behaviour through DT-enabled POE	Active: Presented DT does not integrate user feedback, however, use case presented with subjective experience data collection.
Qian *et al.* (2024)	China	Sustainable Cities and Society	Optimising building system performance to reduce carbon emissions during building operation	Passive and Active: End user location tracking and physical sensors in buildings, additionally, survey data on subjective preferences integrated.

In this context, articles reviewed focus mostly on the thermal comfort dimension, while acknowledging the potential for DTs to expand into other (IEQ) dimensions such acoustic or visual comfort. Applications focusing on improved occupant comfort tend to integrate a wider range of occupant data into their DTs, including feedback prompts from users on their subjective experiences. Examples of these studies include the studies undertaken by Qian *et al.* (2023;2024) in residential building, as well as those in office environments conducted by Abdelrahman *et al*. (2022) and Lee *et al*. (2023).

*Purpose 3***:** *Early failure detection*

Another major purpose identified is the application of DTs for early failure detection of building systems. For instance, the DT application proposed by Hosamo *et al*. (2023a) integrates the end-user feedback with sensor data to determine faulty zones and building system. The DTs data is analysed through Bayesian networks to integrate a logic that can allow for more concrete diagnostics. The suggested model also integrates different ML algorithms to enhance and automate the failure detection process. The study also discusses the emerging topic of the use of ML in processing IoT data in DTs, while resulting analysis showcase very promising accuracy results, ranging from 94% for Fine Tree to 97% for Artificial Neural Networks, these still require substantial computing time. As such, trade-offs between accuracy of results and processing time will remain important considerations in occupant-centric DT data analytics.

Niche Purposes:

A few other purposes for the implemented DTs have also been identified. For instance, Seghezzi *et al*. (2021) model focuses on supporting the FM function through the provision of opportunities for maintenance cost optimisation using camera-based sensors to identify maintenance needs based on occupancy and usage patterns. Another niche application is proposed by Park *et al*. (2018). Their DT provides an early disaster detection system for fire safety, as well as including an interactive AR interface linked to the DT to support occupants with guidelines and feedback during evacuations.

Occupant Data Types

A focus of the SLR is to determine the methods and types of data collected in the identified applications. As such, categorising the different types of data will provide the structure for the following section. In this regard, the conceptual framework from Abdelrahman and Miller (2022) provides a good conceptualisation of data collected as objective data and passive data. The framework in this paper enhances the initial one by adding a dimension of occupant interaction, which can be considered passive (i.e. occupant data collected passively), or active (i.e. direct input from occupants). The following section will present findings regarding the main categories identified: 1) objective/passive occupant data collection, and 2) active/subjective occupant data collection (see Figure 4).

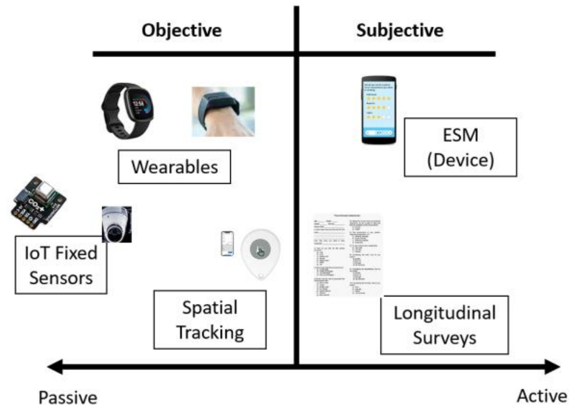

Figure 4. Clustered occupant data means

Objective-Passive: Occupant data integration

The most common tracking method across the studies is the use of passive IoT sensors. Available sensors to monitor occupancy and usage, include CO^2 concentration sensors, light and infrared sensors, camera-based sensors, wireless networks, or RFID sensors (Seghezzi *et al*., 2021). With these initial types of sensors, the aim is the monitoring of zone/area occupancy across the building in real time. Within the sampled papers, the most common occupancy sensors are CO^2 concentration change sensors (Clausen *et al*., 2021; Hadjidemetriou *et al*. 2023; Li *et al*., 2023; Chamari *et al*., 2023), which have a relatively high accuracy rate (over 90%) in detecting general fluctuations in rooms with limited issues regarding data privacy. The data collected through sensors such CO^2 or infrared sensors, while providing data on general occupancy patterns fail to achieve the accuracy of other sensing devices. Shegezzi *et al*. (2023) explore the use of camera-based sensors in their study. These types of sensors while presenting a series of calibration issues, that can affect accuracy when tracking occupants indoors, present additional opportunities for monitoring. First, data from camera-based sensors can potentially yield more granular insights on individual occupancy and usage patterns across the building, as well as provide additional insights on maintenance needs and condition of spaces. This requires further processing and analysis of video data through methods like computer vision.

Other studies present a simplified approach to occupancy monitoring (Seo & Yun, 2022; Massafra *et al*., 2023). These do not include real-time sensing of occupancy, and instead integrate occupancy considerations and room usage data through occupancy schedules. These involve the integration of data from the organisational asset management system, including scheduled room bookings within the building. While this data allows to partially integrate occupancy into DTs in a simplified manner, it fails to achieve the insights that data collected in real-time can yield. On a similar approach, using data captured through climatic stations (e.g. humidity, temperature…), Desogus *et al*., (2023) integrate issues of occupant thermal comfort in their proposed DT solution. These methods lack direct occupant input, and instead they rely on commonly used methods like the Predicted Mean Vote (PMV) to determine problematic areas in buildings.

The final set of passive sensors identified refer to personal wearables. The most comprehensive use of these is within the research studies undertaken by Abdelrahaman *et al*. (2022). In these, participants utilised smartwatches, which enabled the collection of real-time physiological data (i.e. heart rate and corporeal temperature) while inside the physical building. Additionally, perceptual, and spatial data from users was collected. At a smaller scale, and using an experimental setting, Gnecco *et al*. (2023) integrated the use of wearables to track a range of similar physiological data within their DT. While these are promising sources of data, results from co-design workshops by Lee *et al*. (2023) reveal a myriad of challenges. Workshop participants highlighted concerns regarding privacy and security of their personal data collected through wearable sensors. This raises questions about the ethics of such sensors, as well as the practical scalability at commercial scale.

Objective -Passive: Spatial Data

Spatial tracking and the integration of spatial data with semantically rich asset information models, can be considered its own category within passive and objective occupant data. These represent unique challenges for sensing and indoor positioning. As such, it has been the focus of several papers, warranting separate consideration from general IoT sensing (Wang *et al*., 2024; Abdelrahman *et al*., 2022; Gnecco *et al*., 2023).

Tracking occupants indoors has historically been challenging indoors. Unlike urban environments, where GPS can be used with high accuracy, indoor settings present a series of accuracy challenges. Often, a combination of sensors is required for precise spatial tracking. Wang *et al*. (2024) analyse various indoor tracking methods. Ultra-wideband sensors, while precise, are difficult to implement at larger scale. In contrast, more affordable options like wireless or Bluetooth Low-Energy (BLE) beacons, though less accurate (error-prone by 2-5m), are more feasible. BLE beacons, which refer to signal emitters detectable by smartphone applications, enable trilateration for indoor positioning.

Linking user positioning with building components and features can offer deeper insights into end-user behaviours and preferences, however, this integration also presents challenges. In this regard, Graph Neural Networks emerge as a promising solution, enabling mapping the proximity of occupants to building elements and zones. Thus, providing the means to link occupant data to information from these assets (Abdelrahman *et al*., 2022; Gnecco *et al.,* 2023; Wang *et al*., 2024). Recent studies, such as Tripathi *et al*. (2023), are examining GIS in the context of indoor environments. This approach, while challenging, also holds potential for enhancing understanding of spatial dynamics within built assets.

Subjective – Active occupant data integration

Another approach involves the collection of data from occupants regarding subjective and experiential dimensions. In this context, influenced by longstanding research on the measurement of perceptions of comfort from occupants, a few applications have integrated this data within their digital counterparts. Following best practices in comfort studies, Qian *et al.* (2023) conducted a 1-year longitudinal study where they collected 60-80 survey responses per month from residents in the study. These surveys were modelled on the ASHRAE's comfort scale and questions. While the exact points of entry are not clearly established, the approach while yielding additional insights raises questions regarding the labour-intensive nature of integrating data collected from surveys into DTs.

Alternatively, several studies have aimed to utilise the interfaces afforded by wearable sensors and smartphones to collect periodic experiential data from occupants. This approach builds on research on Experience Sampling Methods (ESM), a common approach used in psychology studies (Beal, 2015). Abdelrahman *et al.* (2022) utilised simple ESM to capture the subjective experience of users through a smartwatch application. Lee *et al.* (2023) utilises a similar approach in 15-day study to collect data from office users at regular times of the day, through push notifications prompting for feedback. The collection through these devices allows for automation in the integration of the data, compared with traditional surveys.

Subjective occupant data has the potential to address limitations of traditional occupant surveys (i.e. one-off surveys), by enabling collection of longitudinal datasets on user preferences, potentially leading to opportunities to provide a personalised approach to comfort in buildings (Preiser and Nasar, 2008). However, limitations are not to be overlooked. On one hand, the ethical considerations of personal data collected. Additionally, survey fatigue, a well-known phenomenon is also a consideration (Beal, 2015). Systems to collect data actively from users could be designed to be triggered only when specific events occur, limiting survey fatigue.

Emerging themes: Occupant interaction with DTs

A niche approach regarding occupants that emerged from the reviewed articles is the opportunities for end-user interaction with the DT platforms. Most of the reviewed papers, when discussing interaction with the DT, often refer to the FM or building operator (Chamari *et al*., 2023; Huynh & Nguyen, 2020; Hadjidemetriou *et al*., 2023; Li *et al*., 2023). Within these interaction with data for visualisation and control occurs through dashboards (E.g. Grafana) only accessible for FMs. Tripathi *et al*. (2023) suggest the expansion of these interaction and visualisation to the occupants. Park *et al.* (2018) expands on the end-user occupant interaction aspect. The proposed DT application, centred on early fire detection and evacuation, integrates an interactive AR application to provide occupants with real-time data regarding guidelines and evacuation procedures.

Going a step forward, Lee *et al*. (2023) in their aims to '*democratise*' future DT applications, explore the issue of limited interaction built-in in DTs faced by occupants.

The issue can be mapped out to previous research on smart buildings. They not only define interaction regarding visualisation of data, but also explore the expansion to the control dimension (i.e. ability of occupants to control building systems). Moreover, based on occupant comfort theories, particularly the adaptive comfort theory (de Dear and Brager, 2001), such interaction and control of systems might not only enhance satisfaction but might also yield significant energy savings by increasing user tolerance to discomfort.

Occupant-Centric DTs: Directions for future research

The review highlights a prevalent focus on occupant thermal comfort within occupant-centric DTs. This is evident in the dominance of DTs for energy optimisation of building systems and early failure detection. While some studies touch upon visual comfort for energy savings, other dimensions of IEQ such as acoustics remain largely unexplored. Future research should expand the focus to encompass these, particularly considering the relevance of acoustics in public environments.

The integration of occupant data beyond passive occupancy sensors remains limited. Notably, the comprehensive occupant-centric DT by Abdelrahman *et al*. (2022) stands out for its integration of physiological and spatial data through wearables, offering insights beyond thermal comfort. Leveraging such longitudinal occupant data can provide evidence-based information for design teams, opening avenues for evidence-based design in sectors like healthcare or education.

Finally, Lee *et al*.'s (2023) study underscores challenges associated with occupant-centric DTs. Participants expressed concerns regarding data privacy and ownership, highlighting the need for robust data security, especially when collecting subjective and physiological data. Addressing these challenges will remain key for the successful implementation and adoption of occupant-centric DTs at scale within real-world contexts.

Conclusions

Digital Twins (DTs) represent an emerging paradigm offering multiple opportunities in the AECO sector. This review focused on exploring how recent building DT applications are integrating occupant data. The findings highlight a variety of methods and challenges faced by developers of occupant-centric DTs. The review categorises these approaches based on the level of user involvement required. Additionally, it uncovers the challenges in integrating these data into DT platforms. The primary focus of these so far has been on building performance optimisation, especially in terms of energy efficiency. The review also sheds light on emerging applications and approaches to actively involve occupants, and provides directions for future research.

Reflecting on the early POE studies from the 1960s and 1970s, the central aim was to understand how buildings support end-users, such as understanding the influence of hospital design on patient healing rates or the impact of prison design on inmate behaviour. While common POE methods have provided valuable insights over the years, we argue that new paradigms, especially DTs, have the potential to establish these relationships with more rigorous and longitudinal evidence. Ultimately, this can lead to the design of built environments that more closely align with the needs and requirements of end-users.

The chosen method, an SLR, has several limitations. Firstly, it was restricted to peer-reviewed journals, resulting in a selection of a final 20 articles. The limitation of relying solely on peer-reviewed journal sources may exclude relevant literature from other publication types. With DTs being such a recent topic, preliminary research and applications presented in conferences might provide examples of other alternative applications. Using solely Scopus as the data source may have introduced bias, potentially overlooking relevant studies indexed in other databases (e.g. WoS). The review focused on two primary aspects: the purposes of the DT applications and the types of occupant data integrated. While this approach provided depth in analysing these, it may have overlooked broader aspects of occupant-centric DTs.

A SYSTEMATIC LITERATURE REVIEW OF BUILDING INFORMATION MODELLING (BIM) APPLICATION ON RAILWAY ASSET MANAGEMENT

Hyunjung Yoo[1], Weiwei Chen[1,2*], Diran Yu[1], Tim Broyd[1]
[1] The Bartlett School of Sustainable Construction, University College London (UCL), London, WC1E 6BT, UK
[2] Civil Engineering Division, Engineering Department, University of Cambridge, CB3 0FA, UK

Abstract

Building Information Modelling (BIM) has become a prominent trend in the built environment. Despite numerous countries mandating the adoption of BIM in this context, its integration into transportation infrastructure, notably railways, has progressed gradually. Asset Management (AM) continues to be emphasised in transport infrastructure. This study offers an understanding of BIM-based AM in railways via a systematic literature review (SLR). Although some studies delve into railway BIM-based applications across various life cycle phases, previous research has predominantly centred on the operation and maintenance phases. This paper presents a comprehensive view and proposes further research direction.

Introduction

Building Information Modelling (BIM) has a unique characteristic and can be found in the definitions from the standard, academic and industry fields. Nonetheless, a common thread across these definitions underscores the significance of features such as process, information, and life cycle considerations (British Standards Institution, 2013; International Organization for Standardization, 2018; National Building Specification, 2021). BIM is acknowledged in the academic field for its numerous benefits. Wang *et al.* (2013) arranged the BIM's various advantages: decreased costs, reduced errors, improved estimation, improved coordination, identifying conflicts and enhanced clients' and end-users understanding. Shin, Jung and Kim (2022) and Shin, Kim and Liao (2024) found meaningful benefits through their research on BIM implementation in the design and construction phase of the railway sector, such as cost and management aspects. Based on these advantages, governments across the globe, regardless of their geographical location, are opting to mandate the use of BIM in the built environment. Among them, the United Kingdom is positioned as a leading country globally in the application of BIM (Jaskula and Papadonikolaki, 2021).

Nevertheless, BIM is still slowly being adopted in transportation infrastructure, especially linear transportation infrastructure (e.g. railways, roads, gas pipelines, power lines, rivers and canals). Unlike buildings or other entities, transportation infrastructure's considerable size and intricacy contribute to the relatively recent initiation of BIM adoption. Notably, the application of BIM in railways is often referred to as being in its infancy (Han *et al.*, 2018).

As previously mentioned in the definition of BIM and its ultimate purpose, it is noted that it considers the lifecycle. The BIM lifecycle simply refers to the product lifecycle process, which consists of the concept, design, construction, operation, demolition and disposal (Gajera, 2017). Additionally, the term "sustainability" is a crucial global focus. Through the announcement of SDGs Goal 9, the United Nations emphasises the sustainability of infrastructure. In this paper, the perspective of sustainability is examined through an Asset Management (AM) approach. First, PAS 55- 1 defined the AM definition as 'systematic and coordinated activities and practices through which an organisation optimally and sustainably manages its assets and asset systems, their associated performance, risks and expenditures over their life cycles for the purpose of achieving its organisational strategic plan' (British Standards Institution, 2008, p.2). AM is not a novel concept, but AM is considered a relatively new discipline in the transportation infrastructure field because of the recent need to perform the lifecycle management is necessary for this domain (Garramone, Tonelli and Scaioni, 2022). Alnaggar and Pitt (2019) emphasised that BIM has a big potential in the AM sector.

Among linear transportation infrastructures, railways are environmentally friendly with low carbon emissions. They possess numerous advantages, including the ability to transport a large number of people at once and minimal traffic congestion. Consequently, they continue to garner significant global attention as transportation. Hence, the purpose of this paper is to explore a comprehensive perspective on railway infrastructure asset management using BIM.

This paper mainly comprises four sections. First, the introduction part consists of background information and general understanding. Second, the research methods part demonstrates this paper's systematic literature review (SLR) process. Third, the results and discussion section includes the SLR results and explains them. Finally, the conclusion summarises the overall contents of this paper.

Research Methods

This paper aims to investigate the BIM-applied railway infrastructure AM from a comprehensive point of view. To achieve this, this study conducted a systematic literature review (SLR), which adopted the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methods, as illustrated in Figure 1.

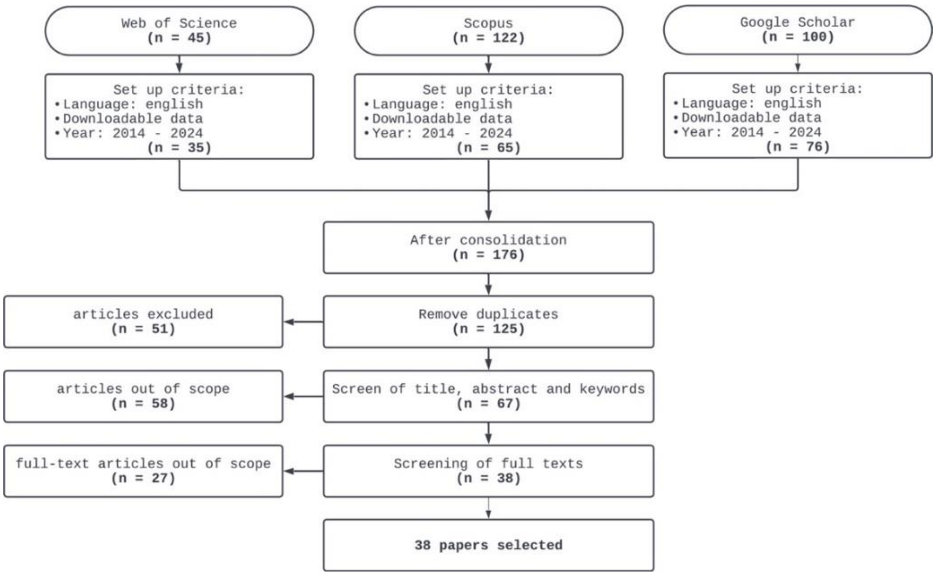

Figure 1: SLR flow chart (adopted the PRISMA method).

First, the authors decided on the keywords for BIM-based rail infrastructure AM. This study's main keywords are BIM, railway and AM. The keywords for searching in the database are set in Figure 2. The reason why the keyword "life cycle" is used not only the keyword AM, because the extended area of AM contains the consideration of the life cycle. Therefore, this review includes the term life cycle to cover all aspects of AM rather than just one specific part of it.

(BIM OR "building information modelling" OR "building information modeling" OR "building information model") AND (AM OR "asset management" OR "life cycle") AND (rail OR railway OR railroad)

Figure 2: Keywords.

This review selected three databases: Web of Science, Google Scholar and Scopus. At first, a total of 267 papers were found from three selected databases. Several criteria were used in SLR in this study. First, the language used is limited to English. Second, the article only includes the downloadable data. Third, the range of years is between 2014 and 2024. BIM is deeply related to cutting-edge technology. Hence, the literature's publication dates are only considered for the past 11 years. These years include the years when BIM exploded in popularity. Fourth, this SLR includes the grey literature (such as conference papers, books and proceeding papers). Including grey literature in this study is important because it allows us to include more current trends and ongoing research. By applying the criteria, approximately 176 papers were selected from the first 267 papers.

The combined search outcomes of three databases, as per four specific criteria, yield a total of 176 scholarly articles. After identifying 51 duplications among the 176 aggregated papers, the resultant set comprises 125 non-duplicated papers. From this point onward, authors examined titles, abstracts, and keywords to filter out relevant papers. In this procedure, 67 papers were identified after excluding the out-of-scope of 58 papers. This study examined all 67 identified documents in the last phase, verifying their relevance. Consequently, the final 38 papers align with the included scope.

Results and Discussion

Results

The 38 identified documents focus on the scope of asset management in railway infrastructure with the implementation of BIM. This SLR investigated papers from 2014 to 2024. Figure 3 shows a gradual increase in the number of papers published. The papers in this review were not published in 2015 or 2024. The years 2021 and 2023, in particular, saw a sudden drop in the published literature than the previous year. The most recently published papers were in 2023, totalling six papers.

In this SLR study, beyond the exclusive analysis of journal articles, this review encompasses grey literature, including conference papers and conference proceedings. The conference category includes both conference papers and proceedings. Specifically, there are 21 journal articles, comprising 55% of the total, and 17 conference papers, representing 45%. An observation is that more proportion of the papers analysed in this review originated from journals.

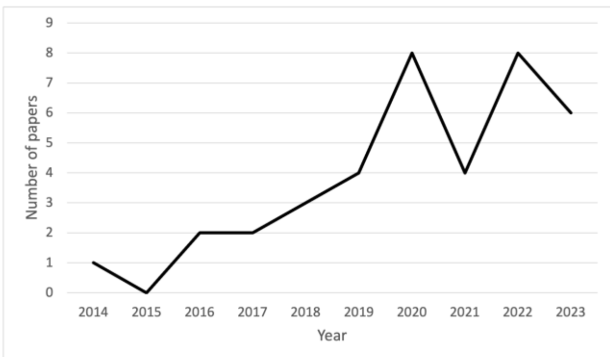

Figure 3: Trend of the published year.

Figure 4 illustrates the percentage of paper types by year. This figure consolidates the observations from published papers years, which are illustrated in Figure 3, and the types of papers published. It visually represents the proportion of papers published each year by type.

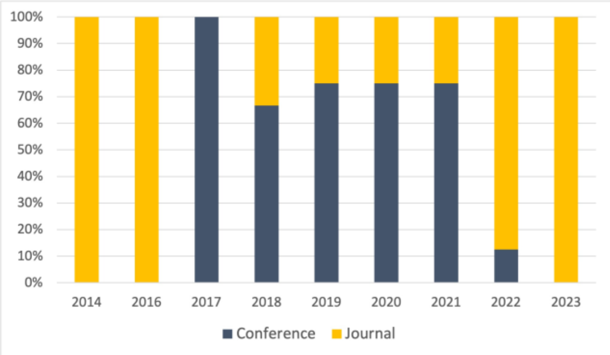

Figure 4: Percentage of paper types by year.

Conducting an SLR on Railway AM with the application of BIM, diverse applications of BIM were witnessed in Figure 5. This included not only the exclusive use of BIM but also the integration of other intelligent technology with BIM, OpenBIM, the application BIM with Industry Foundation Classes (IFC) and System Information Modelling (SIM), the combination with Geographic Information Systems (GIS), the extended application of BIM like the Digital Twins (DT) and the application of BIM in other infrastructure.

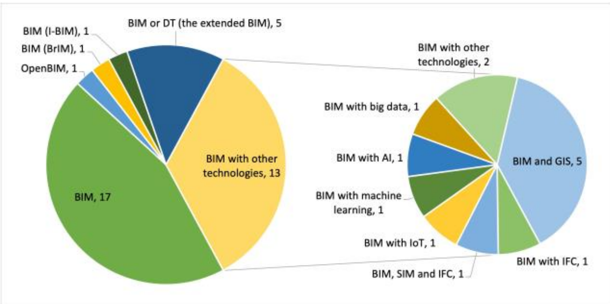

Figure 5: Used BIM classification.

Figure 6 presents a diagram designed to investigate the areas within railway infrastructure where BIM has been applied. The most extensively covered segment, accounting for 38% of instances, involves 12 papers providing a railway. The category of railway-related buildings is closely followed, representing 7 papers. Five papers delve into the application of BIM to railway bridges. Additionally, railway lines, tracks, tunnels and transportation infrastructure are investigated by applying BIM in each of the 2 papers. Lastly, the railway signal, turnout system, and light rail system were studied in one paper with BIM for AM, respectively.

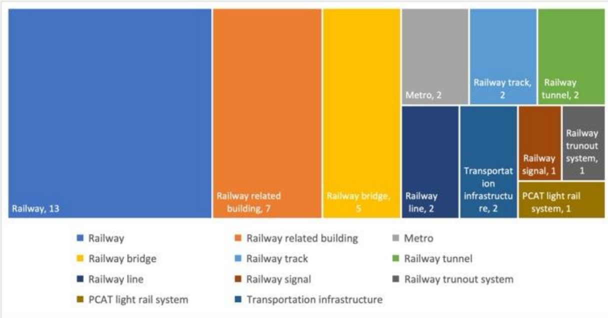

Figure 6: BIM-applicated objects.

Next, an exploration was undertaken to identify the stages or points where BIM has been applied, as depicted in Figure 7. A notable observation is that around 13 papers focused on utilising BIM for AM during all stages of the life cycle. A total of 22 papers were studied related to the design phase, and a total of 17 papers were researched in the construction phase. The operation & maintenance (O&M) phase conducted the AM based on the BIM around 27 studies. Two papers considered the rehabilitation stage.

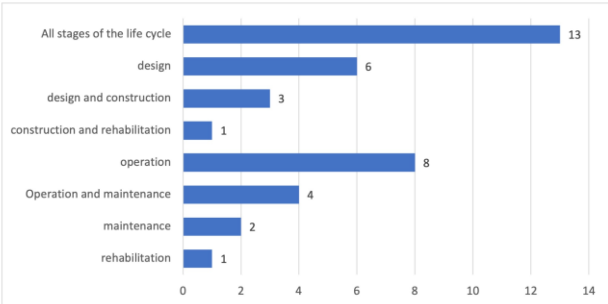

Figure 7: BIM used phases.

The papers analysed in this SLR aimed to implement BIM in railway infrastructure to facilitate AM. The different methods performed to manage AM are summarised in the literature according to the phase in which BIM is applied, as shown in Table 1. The literature shows that there are many different ways to perform AM by each phase.

Table 1: Studies employed to attain the objective at each stage.

	Asset Management	
All stages of the life cycle	Propose the BIM-based approach	(Dan, 2021; Zheleznov, 2021; Alqatawna *et al.*, 2023)
	Investigate the current situation of BIM and provide the countermeasures	(Kurwi, Demian and Hassan, 2017; Han *et al.*, 2018; Belcher and Abraham, 2023)

	Propose the new applications of DT (extended BIM)	(Kaewunruen and Lian, 2019)
	Suggest the application of BIM	(Cheng *et al.*, 2019; Kaewunruen, Peng and Phil-Ebosie, 2020; Wang *et al.*, 2022)
	Propose the data exchange model	(Gu *et al.*, 2022)
	Combine the application of BIM with other technologies	(Gebken, Drews and Schirmer, 2019; Wan *et al.*, 2020)
Design stage	Propose the BIM-based approach	(Lv, 2018; Efanov, Shilenko and Khoroshev, 2020; Pasetto *et al.*, 2020; Liu, 2022)
	Investigate the current situation of BIM and provide the countermeasures	(Sanchez *et al.*, 2014; Akponeware *et al.*, 2020)
	Introduce safety design, risk evaluation system and related theories of BIM	(Xiahou *et al.*, 2022)
	Suggest the application of BIM	(Chen, Hu and Tang, 2016)
	Provide the insight of BIM/GIS interoperability	(Floros, Ruff and Ellul, 2020)
Construction stage	Propose the BIM-based approach	(Großauer *et al.*, 2022; Liu, 2022)
	Provide the insight of BIM/GIS interoperability	(Floros, Ruff and Ellul, 2020)
	Suggest the application of BIM	(Chen, Hu and Tang, 2016)
Operation and Maintenance stages	Develop the BIM-based methodologies	(Wang *et al.*, 2020; Ciccone *et al.*, 2022)
	Investigate the current situation of BIM and provide the countermeasures	(Liu *et al.*, 2023)
	Develop a suitable platform based on BIM	(Hartung, Senger and Klemt-Albert, 2019; Hartung *et al.*, 2020)
	Introduce the new approach to digital asset management	(Love *et al.*, 2018)
	Combine the application of BIM with other technologies	(Boyes, Ellul and Irwin, 2017; Sresakoolchai and Kaewunruen, 2021, 2023; Garramone, Tonelli and Scaioni, 2022)
	Propose the new applications of DT (extended BIM)	(Kaewunruen, Sresakoolchai and Lin, 2021; Kaewunruen *et al.*, 2023)
	Develop a real-time lifecycle assessment-capable paradigm digital twin framework	(Borjigin *et al.*, 2022)
	Propose a solution within the existing CAD/BIM/GIS application	(Bartonek *et al.*, 2023)
Rehabilitation stage	Suggest the application of BIM	(McKenna *et al.*, 2017)
	Propose the BIM-based approach	(Großauer *et al.*, 2022)

Discussion

1) Current

Figure 3 captures related research trends that seem to be increasing overall. The lack of published papers in 2024 is likely due to the fact that the papers have not yet been published at the time of this review. Although the change is not dramatic and fluctuates between 2020 and 2023, it still showed a rising interest in the relevant keywords in recent years. In other words, the escalating quantity of published papers can be interpreted as a meaning of an intensifying interest in the associated keywords, signifying rising scholarly attention to these subjects. Figure 4 demonstrates the proportion of published paper types by year. The research was found to be ongoing, with a balance of journal articles and conferences being published. Figure 5 shows the current research on BIM type. While the use of only BIM remains prevalent, a noticeable adoption of BIM in more complex integrations has also been observed. For example, BIM for infrastructure, open BIM, BIM with SIM and IFC, BIM/GIS, extended BIM (DT) and BIM with other technologies. There were noteworthy attempts to expand its applications through various methods.

In the AEC sector, architecture is widely known as the domain where BIM has been most effectively applied and advanced. It was assumed that the reviewed studies would primarily focus on building research. However, Figure 6 revealed that BIM is utilised in a much more comprehensive range of areas. Likewise, the expectation was that most research would be confined to design and construction; however, it was observed to be applied across various domains, especially O&M. Figure 7 illustrates the diversity of BIM application phases. This indicates its diverse application from design to redecoration and its multifaceted implementation across multiple stages, not only the O&M phase. This illustrates the potential of BIM's diverse field of applications, further extending to all stages of the lifecycle.

Table 1 highlights the BIM-based AM. Each study was conducted using various methods at each stage to achieve its objectives. The design and construction phases have been studied in common research: suggest the application of BIM, investigate the current situation of BIM and provide countermeasures, propose the BIM-based approach, and provide insight into BIM/GIS interoperability. In the O&M phase, there were also studies such as the BIM-based approach, investigating the current situation of BIM and providing the countermeasures, but also the development of BIM with other technologies, platform construction, and DT (extended BIM) related studies were characterised differently from other phases. The methods used in all stages of the life cycle use most of the methods used in other stages. BIM application and a BIM-based approach were proposed for the rehabilitation phase. A common method used throughout the entire phase to apply BIM for AM was the proposed BIM-based approach. It can be seen that a lot of research has been done to study BIM-based approaches.

On the other hand, the challenges have been noticed in papers. In general, while the authors explained that they needed to improve their study, scholars emphasised the limitations of their studies, such as the specific performance of the application of BIM (Chen, Hu and Tang, 2016), information exchange (Floros, Ruff and Ellul, 2020; Kaewunruen, Peng and Phil-Ebosie, 2020), limitation of standards (Floros, Ruff and Ellul, 2020)and limitation of guidelines (Love *et al.*, 2018). In order to perform AM using BIM on a railway, there are obvious difficulties in terms of performance, but it is especially difficult to exchange information.

2) Future

The findings of Table 1 describe the different approaches that BIM has been used in railway infrastructure to achieve the AM. This can be connected with future research directions that are frequently mentioned in the literature's future research section. First, many of the authors described the need to develop their studies more deeply. Therefore, future research seems to study the methods that were used more deeply, as mentioned in Table 1. Second, future studies could be proposed on the combination of Table 1 methods and the literature’s mentioned limitations and future research suggestions. The keywords that are mentioned as limitations of the studies are the specific performance of the application of BIM, information exchange, and limitations of standards and guidelines. In several papers, keywords frequently mentioned in concluding remarks regarding future research directions include developing the strategy, effectiveness, efficiency, intelligence, and interoperability. In order to develop these keywords, future research might be conducted using the methods mentioned in Table 1. For example, investigating the current status of related keywords and finding the problem and countermeasure, developing a BIM-based approach, combining the application of BIM with other technologies, proposing the data exchange model, developing a new approach to digital asset management or developing the insight of interoperability.

Figure 5 demonstrates that many studies are currently conducted on BIM alone and BIM with other technologies. This indicates the potential for future applications of BIM in infrastructure AM. This shows the BIM potential of BIM integration with other complex technologies. Especially in BIM or DT and intelligent BIM, there is an emerging theme advocating for the advanced application of BIM, extending into dimensions such as 4D, 5D, 6D, and 7D, alongside the integration of various intelligent technologies. The occurrence of DT in asset management indicates a significant change towards higher integration, especially with BIM technology. This combination emphasises the need for further investigations on BIM within the context of DT. Research efforts like this are crucial for discovering innovative technologies and gaining useful knowledge about asset management. This, in turn, promotes the creation of more advanced and efficient asset management systems.

Conclusions

This paper aims to investigate the current trend and provide a comprehensive view of BIM-applied rail infrastructure AM. This paper adopts the SLR review, which includes the grey literature and uses three databases. As a result, 38 papers were selected for review. While conventional BIM applications are prevalent, research combining BIM with other technologies is also diverse. Moreover, BIM applications are conducted beyond the general railway context, encompassing a variety of targets such as buildings, bridges, systems, signals, and more. Although the majority of BIM applications for AM are concentrated in the O&M phase, they are also performed in various areas. With the current prominence of these keywords, the research trend is expected to continue, with the anticipation of further studies. Based on the studies that have been conducted, limitations of the studies and suggestions for future research are discussed. In future research, not only research focusing on the single use of BIM but also BIM integration research incorporating various intelligent technologies is expected. Furthermore, this is expected to employ real-time data integration to implement DT, enabling holistic Asset Management.

INCENTIVE MECHANISM FOR IPD WITH MULTIPARTY CONTRACT BY USING A PROBABILISTIC COST AND RISK SOFTWARE

Simon Christian Becker[1], Carl Philipp Friedinger[1], and Philip Sander[1]

[1]University of the Bundeswehr Munich, Neubiberg, Germany

Abstract

Participants of major projects have different interests in each tunnel project. A solution is to align the interests using the Integrated Project Delivery (IPD) with an incentive and multiparty contract (MPC). There is no paper in the literature on how to design an incentive for MPC. Starting with a deductive approach, an incentive where all participants benefit the same is designed. An inductive approach is used for validation. Furthermore, for the inductive approach, a risk software tool is used, and a separately developed Excel sheet. Finally, the mechanism's mode of action is presented and validated.

Introduction

Significant cost and schedule overruns in major projects especially in tunnel construction show that risk management is often not given the importance and necessary integration in project management that it should have (Flyvbjerg 2014). To be able to measure and control costs as well as deadlines against the defined targets, it is necessary to assess costs and risks transparently and take them into account appropriately. Nevertheless, especially in tunnel construction, there are always unforeseen and unknown risks that make this difficult.

To align the interests of all stakeholders seems like an unrealizable task. The reason is that the interests are so different. The owner aims to finish the project as soon as possible whereas the contractor is willing to do almost anything to maximize his profit. Given these almost conflicting interests, it takes all the more effort to complete tunneling projects on time and within budget. The traditional contract format fixed price transfers risks from the owner to the construction company (Becker 2022). However, the result is a high potential for claims. As described in the beginning the solution is to align the interests of all the participants and a good way to do that is an incentive contract.

Integrated Project Delivery (IPD) is used for major projects to align these objectives. Therefore, a multiparty contract is used. This means that the risks are shared and there is also an incentive mechanism to align the objectives of all parties involved.

Since there's no sufficient research on incentive mechanisms for IPD, this article will show how an incentive mechanism can be developed, and in which all participants participate in the project in proportion to their direct project costs.

To this end, the basics of IPD, multiparty contracts, and incentive contracts are first outlined. The research gap is highlighted and the software tool used for cost and risk calculation is introduced.

The description of the development of an incentive mechanism for MPC follows. First, it is described using a deductive approach.

The deductive description is succeeded by an example tunnel project (inductive). This example project is used to validate the theoretical concept.

Integrated Project Delivery (IPD)

The basic idea of IPD is to enable better handling of major projects. The aim is to achieve a faster and cheaper construction process while increasing quality. With this form of execution, an integrated execution team consists of at least the client, planners, and construction companies. They work cooperatively and project-related. All those involved in the project should be aware of the client's objectives from the outset and jointly develop project goals so that everyone involved is aware of the project requirements, and the best possible solutions to achieve the set objectives (Cheng et al. 2019).
To be able to consider identifiable risks and implement solutions cost-effectively in the planning phase, all available knowledge has to be taken into account (Warda 2019).

The core principles for IPD can be stated as follows (Ahmad et al. 2019):

- Early Contractor Involvement of core stakeholders: client, contractor, and planner prior to the start of planning (Friedinger and Becker 2023),
- joint risk management,
- incentive mechanism,
- collaborative working methods,
- joint decisions and
- conflict management.

In the following, the function of a multiparty contract is described in order to better understand the function of the delivery model.

Multiparty contract (MPC)

A multiparty contract is a contract between at least three parties: owner, planner, and construction company. This means that all parties involved in construction and planning are bound together by a uniform contract with each other. In addition, other project participants such as specialist planners, specialized finishing trades, subcontractors, or independent consultants can be included in the contract.
The multiparty contract also promotes cooperation in terms of liability and combines innovations. The incentive

contract realizes a corresponding alignment of goals between the parties. To achieve the alignment the incentive of the MPC must be designed in a way that everybody participates according to the contribution regarding the total costs of the project.
The incentive mechanism for the use case is shown below. The success of an IPD depends largely on the correct choice of the target cost. This must be done individually based on the results of the probabilistic risk analysis and the integral consideration of cost and schedules (Sander et al. 2022, Becker and Roman-Müller 2022).

Focus on Cost Plus Incentive Fee

A Cost Plus Incentive Fee (CPIF) is used when an objective relationship can be established between the fee and performance measures such as actual costs, delivery dates, and performance benchmarks. In the case of highly uncertain and speculative construction projects, it's necessary to use this kind of contract. The owner assumes the risks inherent in the contract-benefiting if the actual cost is less than the expected cost-losing if the work cannot be completed within the expected cost of performance (Becker and Sander 2023; Kerzner 2022).

Explorative Literature Analysis for finding the research gap

By using Google, Google Scholar, Scopus, and Opac+ UniBw an explorative literature analysis was made.

The search strings for this were:

- Incentive mechanism for multiparty contract
- Multiparty contract and incentive mechanism
- Incentive Mechanism for IPD
- IPD and Incentive Mechanism

Different approaches to incentive design were found during the research. These ranged from blockchain applications to theories regarding incentive design.
However, it was not possible to find a concrete implementation of an incentive mechanism for the IPD using an MPC. Therefore, there is a research gap in the area of incentive design for MPCs.
After finding the research gap the basics for the cost and risk calculation will be described. This will be later on needed for the description of the deductive and inductive approach.

Integral Modelling of Cost, Deadlines, and Risks

Cost Components

The use of cost components that build on each other aims to create cost transparency by specifying a clear cost structure that can be applied from an early planning stage to construction completion. The main cost components are (Sander and Becker 2023):

- Base Cost (B): Cost if „everything goes according to plan", without reserves for risks or approaches for escalation (price increase).
- Risk (R): Cost resulting from threats and opportunities that can occur but are not certain to occur (probability of occurrence).
- Escalation (E): Cost resulting from the forecast price increase.
- General Business Expenses (GBE): Include all costs that cannot be directly allocated to this specific construction contract but are incurred by the company as a whole.
- Profit (P): Amount that remains from sales - i.e. the total income of a company - after deducting all costs.

The sum of Base Cost, Risk, and Escalation are the direct project costs (DPC) (1).

$$DPC = B + R + E \qquad (1)$$

The sum of the DPC with the general business expenses and the profit is the Target Cost (TaC) (2).

$$TaC = DPC + GBE + P \qquad (2)$$

RIAAT (Risk Administration and Analysis Tool)

Description of the Software Application

Risk Administration and Analysis Tool (RIAAT) is a desktop application and therefore a stand-alone application.

RIAAT was developed to manage and integrate cost, risk, and schedule analysis for large-scale construction projects.
RIAAT considers the interdependence of cost and schedule. Time-related costs, risk impact, incentive fees, etc. are factored in to optimize your project in terms of cost and schedule (Sander et al. 2021; RIAAT 2024). The benefits of RIAAT are:

- Build a schedule including risks and uncertainties.
- Link schedule and cost using drag-and-drop.
- Consider cost caused by schedule risks.
- There's never only one critical path. Takes every option into account with multiple critical paths.

Figure 1 shows the connection between Cost, Risk, and Schedule and the result as an example of the delay cost.

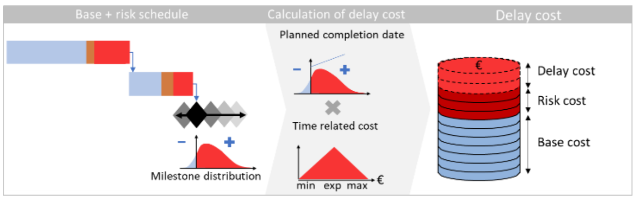

Figure 1: Example integrated calculation of delay cost (RIAAT 2024)

RIAAT bases the decisions on the best risk-benefit ratio shown in Monte Carlo simulations creating probability distributions that allow you to assess the level of probable cost or time overruns with regard to your defined budget or milestone date.

The benefits are:

- Consider uncertainties at all levels.
- Use ranges (bandwidths) instead of single deterministic numbers, and
- Bottom-up aggregation for transparent results.

Both in the business and financial sector and in the construction industry, a statistically determined fractile value of the value at risk (VaR) is used to quantify this monetary sum. To determine this fractile value, a certain probability value must be set depending on the assessment of the complexity of the project and the risk appetite or risk acceptance (Bergmeister 2021; Bergmeister 2022).

With X as a variable with the distribution function (3).

$$F_x(x) = P(X \leq x) f\text{ür } x \in \mathbb{R} \qquad (3)$$

Random losses are represented by the positive values of the random variable X inverse of the distribution F_X^{-1} and the confidence level with $\alpha \in (0,1)$.
The VaR will be defined in (4) (e.g. Figure 2).

$$VaR_\alpha(X) = F_X^{-1}(\alpha) \qquad (4)$$

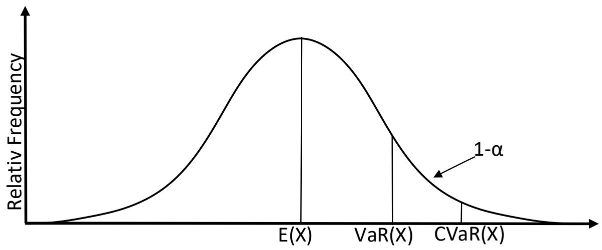

Figure 2: Value at Risk

Deductive Approach for Designing the MPC Incentive

Accordingly, it is important to design the incentive for the MPV in such a way that everyone participates equally in this contract. This means that everyone participates in the potential bonus according to their share of the production costs of the project. The following is an example of how the DPC are jointly pooled and how the bonus is subsequently shared.
Figure 3 shows all contractual partners (CP). The representation of CP 1 to CP 3 refers to the Owner. The client is not considered further in this example, as it is assumed that the client does not contribute to the costs with the MPV. First, each contractor determines its DPC. As mentioned above, this is done using probabilistic methods and in the form of a work calculation.

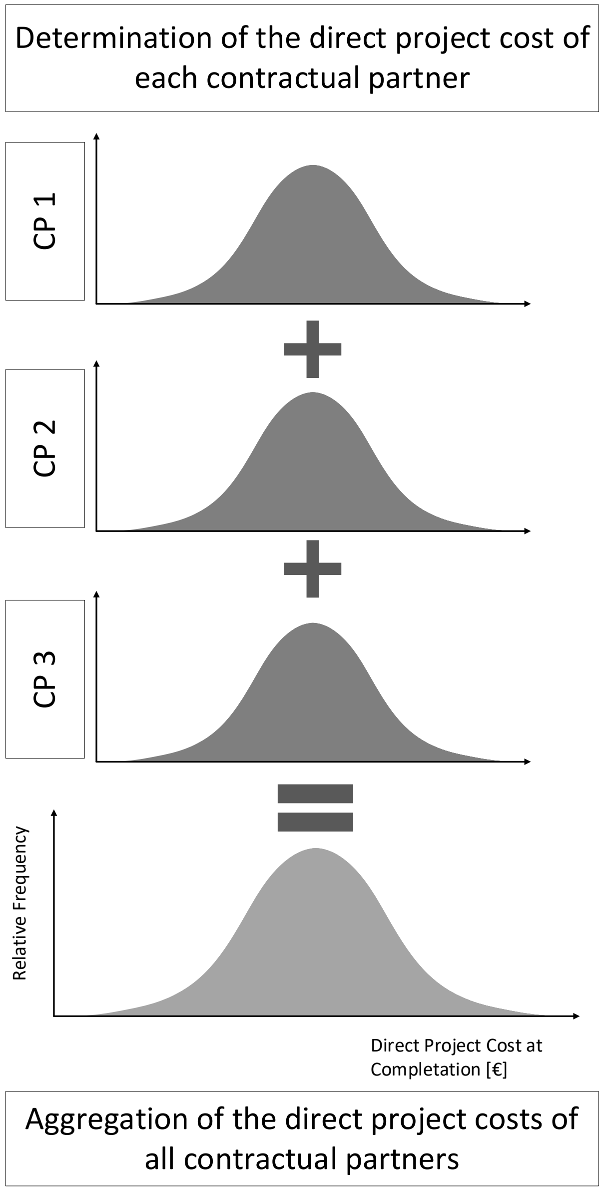

Figure 3: Determining the manufacturing costs of all contractual partners

Once the DPC for the individual contract partners have been determined, the functions (in this case three, e.g. Figure 3) are aggregated. This creates a function for the manufacturing costs. All contract partners must then decide on a P-value for the DPC. Figure 4 shows a distribution and a P-value of 50. This stands for a probability of 50% (P50) that the budget will be underrun. Conversely, there is a 50% probability that the budget will be overrun.

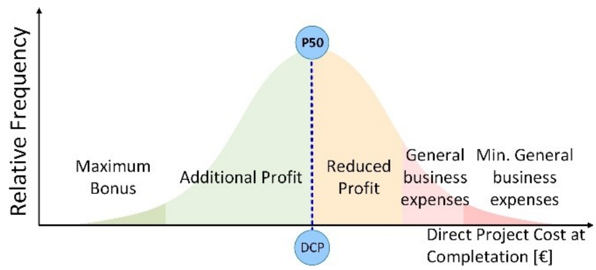

Figure 4: Determination of the P-value of the individual contractual partners

Once the P value has been set, the TaC can be assigned again for all CPs. Involved in the TaC are the GBE and P. This develops the incentive mechanism for the CPs.

Figure 5 depicts an incentive mechanism. The horizontal axis shows the potential final costs for the client, and the vertical axis shows the compensation of the contractor. The light blue dashed line shows the owner/contractor share-ratio. In this example, the ratio was set at 50/50 across all areas. This means that if the TaC is undercut or exceeded, the deviation is split equally between the two partners. Additionally, Figure 5 shows the target cost and the target profit. Both are set in the contract.

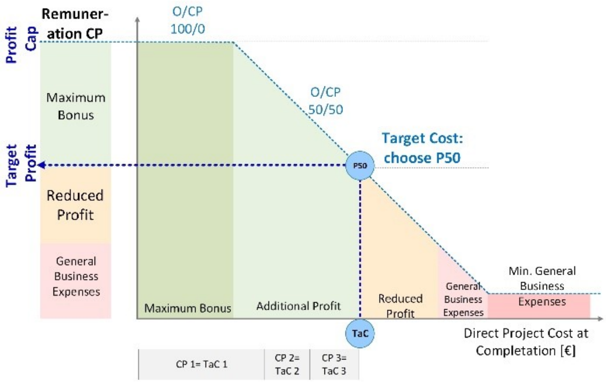

Figure 5: Aggregation of distributions and determination of target costs

Once the construction work has been carried out and the construction project has been completed, billing can take place (theoretical). Figure 6 compares the actual Construction Costs (CC) with the previously calculated DPC and the real TC. Below the horizon line is the area of the DPC.

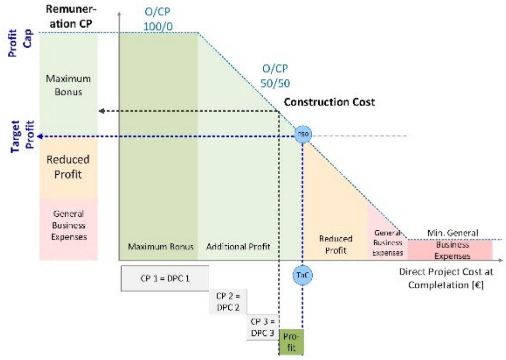

Figure 6: Settlement and distribution of the bonus

Figure 6 shows a scenario at the end of the project in which the Construction Cost (CC) is lower than the agreed TaC. Due to the lower CC, the grey dashed line shifts to the left. This can be achieved by, for example, increased efficiency, the use of new, innovative construction methods, etc. In this case, the contractor generates a bonus of 50% of the savings in addition to the target profit (increased profit). The remaining 50% of the savings goes to the client (Becker and Sander 2023).

Use Case – Tunnel Project

Project Description

A fictitious sample project in this paper is used to illustrate the process. It is based on experience from major European railway base tunnels. This 14-km twin-bore tunnel consists of several Tunnel Boring Machine (TBM) drives as well as Drill & Blast (D&B) drives in different geological formations, an access shaft, emergency stops, various cross cuttings, and inner linings. The project is separated into five lots. Lot 0 is for the access road construction, lot 1 is for the crosscut and the New Austrian Tunneling Method (NATM), lot 3 is for the access shaft, and lot 4 is for the underground refuge. So for the example project are four contractors needed. Lot 0 is not considered any further in the project description. It is no longer relevant in the consideration.

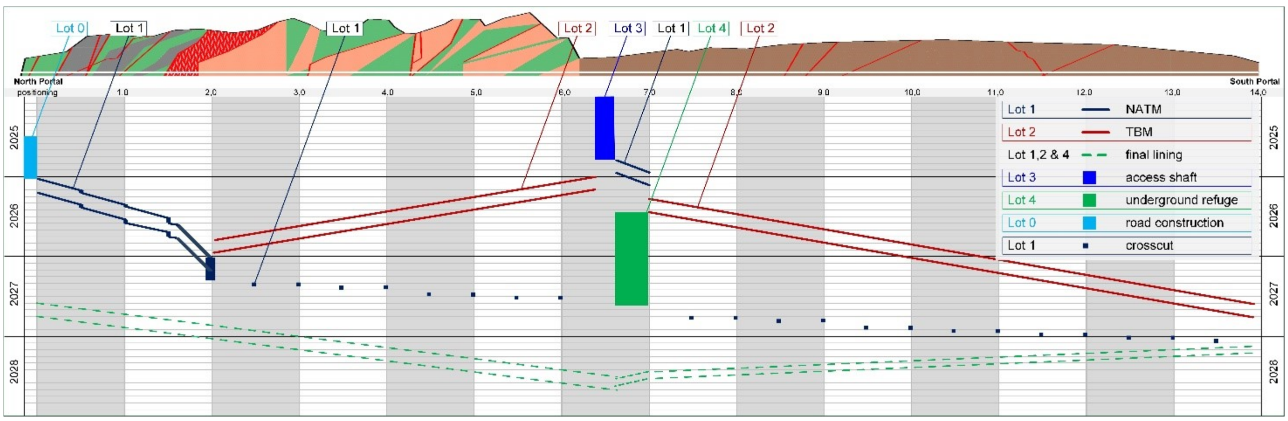

Figure 7: Path-time diagram fictional tunnel project

Inductive Approach

After the description of the deductive approach in the section above, this section shows the inductive approach by using a fictitious tunnel project. The IPD is applied with an MPC. The remuneration model is a cost-plus incentive fee. The authors created a fictitious tunnel and determined the base costs, risks, and price increases. The information was determined in a workshop and validated and adjusted accordingly by the third author. The data was entered into the RIAAT software and analyzed probabilistically. In the process, 35 risks have been included in the model as examples. The individual lots were evaluated using another specially developed Excel sheet.

The DPC (production costs) were determined for lots 1-4 and a VaR of 50% was set. After determining the DPC the GBE and the P, together a percentage premium of 8%, were multiplied by the aggregated DPC. The calculation of the DPC, the TaC, Savings, and bonus allocation are shown below.

Description of the procedure for a MPC

First, the DPC of all parties of the multiparty contract are calculated. In our case, there are four contractors. The direct project costs are composed of the base costs, risks, and price increase (Sander and Becker 2023).

Together with the determination of the direct project costs distribution functions are created, one for each member of the multiparty contract (e.g. Figure 8). Then, the P-values of the contractual partners are determined. The P-value indicates the probability of the target costs occurring. For public construction projects, as is almost always the case in tunnel construction, this value is between 50% (P50) and 90% (P90) (e.g Bergmeister 2021).

In Figure 8, the P-value was set to P=50 for this example. So, the direct project costs are for Contractor Lot 1: 90.3 Mio. €, Contractor Lot 2: 375.9 Mio. €, Contractor Lot 3: 11.1 Mio €, and Contractor Lot 4: 25.7 Mio. € (see also Table 1). The calculation was done with the software RIAAT and included all costs, risks, price increases, extra costs for schedule delays, and so on.

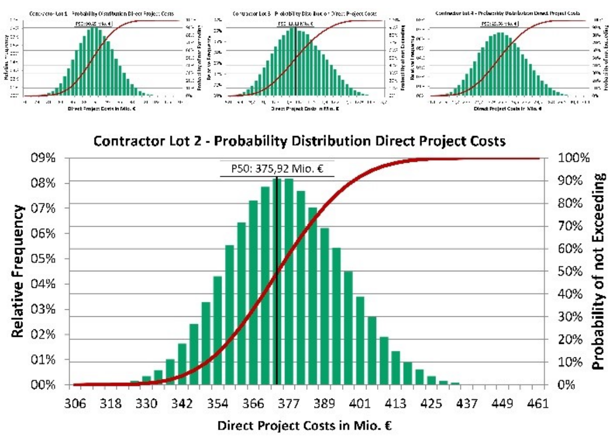

Figure 8: Distribution functions of direct project costs for each contractor

The direct project costs are determined by all members of the multiparty contract or all contractors and the client. In this example, the contractual partners would set the direct project costs at 502.9 Mio. € by aggregating all contributions of all participants.

In the next step, the TaC for the project is defined jointly and the incentive mechanism is set. In this use case, the owner and the contractors decided to add 8% to the Direct Project Cost, 5% for General Business Expenses, and 3% for Profit. The jointly agreed 8% is added to the aggregated distributions and the Target Cost is set on P50 at 543.43 Mio. € (see Figure 9). This later serves as the basis for billing.

Figure 9: Probability Distribution Target Cost

Table 1 shows all the results of the example project. As described above, the VaR was set at 50%. The distribution between the client and contractor is 50/50. For example: if €5 million is saved, the client would receive €2.5 million and the contractors would also receive €2.5 million. The Target Cost was described previously. The table also shows jointly agreed DPC in Mio. €, the share of each contractor of the DPC and the agreed general business expenses and profit. This is the foundation for the Target Cost. The CC and the cost of GBE, and Profit based on the TaC are shown as well. Together, they form the Total Cost (ToC) in Mio. €. Also, the savings regarding the DPC are depicted in € and as a percentage. Finally, the table shows the share ratio, the bonus in millions for every contractor, and the bonus share of each contractor regarding their specific Target Cost.

Table 1: Costs and Savings for the Example Tunnel Project

	Contract Lot 1	Contract Lot 2	Contract Lot 3	Contract Lot 4	∑ and Share Owner
Direct Project Costs P50 in Mio. €	90,25	375,92	11,11	25,66	**502,94**
Share of Direct Project Costs in %	*17,9*	*74,7*	*2,2*	*5,1*	*100,0*
General Business Expenses and Profit in %	*8,00*				
General Business Expenses and Profit in Mio. €	7,26	30,26	0,89	2,07	**40,48**
Probability Target Cost	*P50*				
Target Cost in Mio. €	97,52	406,18	12,01	27,72	**543,43**
Construction Costs in Mio. €	89,31	373,55	10,91	24,09	**497,86**
General Business Expenses and Profit based on Construction Costs in Mio. €	7,14	29,88	0,87	1,93	**39,83**
Total Cost in Mio. €	96,45	403,43	11,78	26,02	**537,69**
Savings in Mio. € regarding Direct Project Costs	0,95	2,37	0,20	1,56	**5,08**
Savings in % regarding Contractors Direct Project Costs	*1,05*	*0,63*	*1,80*	*6,10*	***1,01***
Share Ration Savings Owne/Contractor	*50/50*				
Bonus in Mio. €	0,46	1,90	0,06	0,13	**2,54**
Bonus in % regarding Target Cost	*0,47*	*0,47*	*0,47*	*0,47*	*0,47*

(5) shows how to calculate the Direct Project Cost (DPC) for all four contractors in the use case.

$$\sum DPC_{c1-c4} = DPC_{c1} + DPC_{c2} + DPC_{c3} + DPC_{c4} \quad (5)$$

To get the percentage share for any contract (P_{DPCci}) of the DPC see (6).

$$P_{DPCci} = \frac{DPC_{Ci}}{\sum DPC \times 100} \quad (6)$$

With (7) the total of percentage of GBE (P_{GBE}) and contractor Profit (P_{CP}) is calculated.

$$P_{GP} = P_{GBE} + P_{CP} \quad (7)$$

The premium of General Business Expenses (GBP) and Profit can calculate with (8).

$$GBP_{\sum} = DPC_{ci} \times P_{GP} \quad (8)$$

Now, to calculate the Target Cost (TaC) of the project the sum of the DPC is multiplied by sum of the percentage of the GBE and Profit.

$$TaC = \sum DPC_{c1-4} \times [1 + (GBE + P)] \quad (9)$$

The calculation of the Target Cost of each Contractor (S_{TCci}) is shown in (10).

$$S_{TCci} = TaC \times \frac{P_{DPCci}}{100} \quad (10)$$

After the calculation for the project is done, the construction phase of the project follows, and at the end the billing. The contractors will receive the Construction Cost (CC) which are occur in reality. The calculation for the total CC can be seen in (11).

$$\sum CC_{c1-4} = CC_{c1} + CC_{c2} + CC_{c3} + CC_{c4} \quad (11)$$

Now, to get the Total Cost (ToC) of the project the CC are multiplied by the GBE and Profitas shown in (12).

$$ToC = \sum CC_{1-4} \times \left(1 + \frac{P_{GP}}{100}\right) \quad (12)$$

The savings of the different contracts can be calculated by subtracting the CC from the DPC for each contractor (e.g. 13).

$$Sa_{ci} = DPC_{ci} - CC_{ci} \quad (13)$$

To get the savings in percentage for each lot, divide the Savings (Sa_{ci}) and the DPC_{ci}.

$$P_{Saci} = \frac{Sa_{ci}}{DPC_{ci}} \times 100 \quad (14)$$

At the end of the project, the bonus needs to be shared between all contractors. (15) shows the formula. With Sa_{ci}, the percentage of each contractor's P_{DPCci}, and the Share Ratio (SR) the bonus can be calculated.

$$Bonus_{ci} = \sum Sa_{ci} \times P_{DPCci} \times \frac{SR}{100} \quad (15)$$

Finally, the percentage of the Bonus P_{Bonus} results from each $Bonus_{ci}$ in relation to the Target Cost of each contractor (TaC_{ci}) (e.g. 16).

$$P_{Bonus} = \frac{Bonus_{ci}}{TaC_{Ci}} \times 100 \quad (16)$$

As this is an example project, it was assumed that only around 50% of the risks occurred in the example project. As a result, the contractors and the client were able to generate cost savings of €5.08 million. Due to the 50/50 split, €2.54 million is distributed among the contractors involved. The distribution key for the bonus payment depends on the participation of the Targets Cost. Contractor Lot 1, for example, has a share of the target costs of 17.9%. Therefore, his share of the bonus is also 17.9 %. Consequently, Contractor Lot 1 receives € 0,46 million. The distribution of Contractor Lots 2-4 is equivalent.

The distribution of the bonus in % about the target cost is thus equally distributed among all participants. Each one of them has a bonus share of approx. 0.47 % of his TaC. This clearly shows that all participants in the project participate equally in the bonus of the project and thus an actual target alignment between all participants takes place.

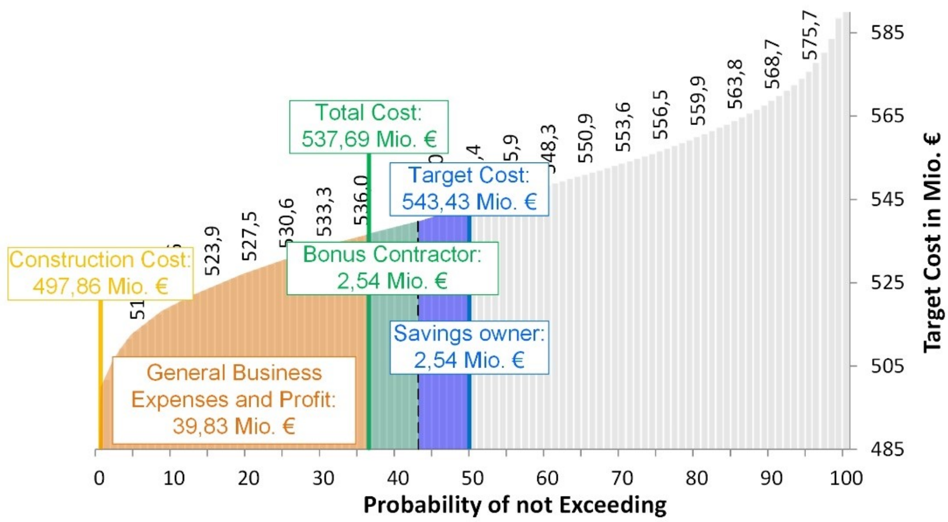

Figure 10: Results of the example construction project with a Lorenz Curve

Figure 10 shows the results with a Lorenz curve. The TaC are 543.43 Mio. € (P50) and were calculated together. The Construction Cost shows the cost that accrued for the tunnel project. The Total Cost are the cost, that the owner has to pay for the construction project (here 537.69 Mio. €). It includes the Construction Cost (here 497.86 Mio. €). and general business expenses as well as profit (here 39.83 Mio. €). In this example, the contractors' bonuses are not included in the Total Cost.
The shares of the savings and bonus are presented in more detail in Figure 11.

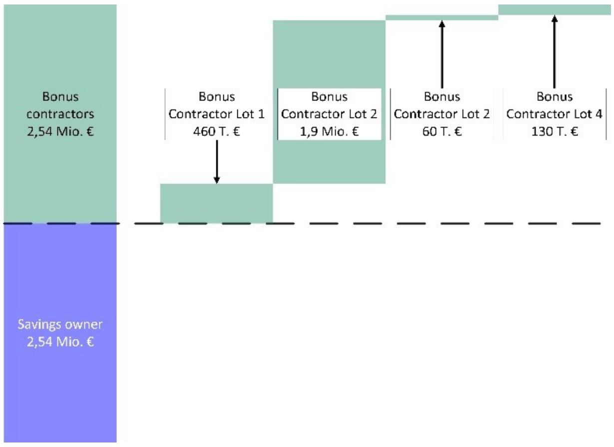

Figure 11: Shares of Savings and bonuses for the example project

According to the share ratio, the savings are split 50/50. The owner gets € 2.54 million and the contractors get the share the same amount among themselves. Every contractor gets his share according to equation (15). The calculation for Lot 1 is as follows (17).

$$Bonus_{c1} = 5.08\, Mio. € \; x \; 17.9\% \; x \; \frac{50}{100} = 460\, T. € \quad (17)$$

The calculations for the other lots are equivalent.

Conclusions

This paper shows the application of risk software for creating an incentive mechanism for the IPD with MPC. The deductive process was validated with an inductive process to check whether the incentive mechanism treats all parties equally.
The example tunnel with several lots and the use of IPD, a cost-plus incentive fee contract, and a multi-party contract were used to demonstrate the use of the software. An incentive system was developed for a multi-party contract whereby all parties involved can participate in the success of the project. This aligns the interests of all parties involved and they work together for the success of the project. By linking the incentive to the respective parties, everyone is always obliged to do their best for the project. A multi-party contract with a cohesive incentive mechanism between all parties therefore leads to joint project success.

Outlook

Incentive mechanisms can be designed in a variety of ways. Currently, the literature generally lacks simple considerations on how all parties participate equally in an MPC. This is particularly important, as otherwise, not all parties will work in the best interest of the project goals. This simple example shows an incentive mechanism for multi-party contracts in which all parties participate equally. In order to further validate the results, further use cases need to be created and the incentive effect needs further investigation. In addition, an application should be used in a large-scale project and the results should be shared and further optimizations incorporated into the research. This would further improve the mechanism of action on the one hand and on the other hand the design of the incentive mechanism.

ASSESSING THE BENEFITS OF DIGITAL TWINS TOWARDS THE FORMULATION OF WHOLE LIFE CYCLE VALUE PROPOSITIONS: A SYSTEMATIC REVIEW

Omar Abbas, Nicola Moretti, and Tim Broyd
University College London, London, United Kingdom

Abstract

Digital twins have been advocated for adoption in the construction industry to tackle many of its inherent challenges. There has been a lack of clarity, however, in demonstrating their realized value with some enterprises facing difficulties justifying their investment. This study employs a systematic review method to extract empirical evidence demonstrating the value of digital twins. Some realized Digital Twins' benefits and costs were demonstrated in the articles, but there were no investment appraisal studies that provide a full account of value propositions. Future studies adopting case studies method are recommended to assess the value propositions of digital twins.

Introduction and background

Context

In the era of the fourth industrial revolution (Industry 4.0), businesses have been adopting digital technologies to drive further efficiencies in their processes. The proliferation of digital technologies has been transforming traditional workflows while promoting further productivity gains. The Architecture, Engineering, Construction, and Operation (AECO) industry, however, remains to be one of the least digitized industries (Agarwal, Chandrasekaran and Sridhar, 2016) with a very slow uptake of new technologies (Davies and Harty, 2013).

The AECO industry faces several inefficiencies such as low levels of productivity and a fragmented supply chain (Opoku et al., 2021). As a project-based industry, the delivery process is transient where the output is unique (Gann and Salter, 2000; Morris, 2004), and this inhibits the industry from adopting the benefits of repeatability like that in the manufacturing industry (Fernández-Solís, 2008). Projects are usually initiated for the purpose of creating new value (Winch, 2010).

Capitalizing on different digital technologies, a Digital Twin (DT) has been argued to be a driver of value in the AECO industry. A DT is a real-time virtual replica of a physical asset (Grieves and Vickers, 2017) with its use extending throughout the whole life cycle of the physical asset (Madni, Madni and Lucero, 2019). It employs a set of different technologies with the aim of achieving bidirectional flow of data between the physical asset and digital counterpart (Alizadehsalehi and Yitmen, 2023). This automated flow of data along with the use of data analytics can create several benefits including reduced rework, better energy management, and lower construction costs (Opoku et al., 2021). Despite their attested value and advancements in other industries such as Aerospace, and Manufacturing (Xie et al., 2023), the AECO industry has been slowly adopting this trend (Opoku et al., 2022).

In the context of their potential value, DTs can tackle many of the AECO industry's underlying inefficiencies and issues. However, due to the lack of clarity in their value propositions (Opoku et al., 2023), they have not been widely adopted in practice. Furthermore, construction enterprises find difficulties justifying the additional DT investment. It was even asserted that the value of DTs is yet to be defined (Pregnolato et al. 2022), and Shahzad et al. (2022) suggested the need for demonstrating their benefits as new technologies are adopted after their cost-effectiveness is demonstrated in real-world projects.

Research aim, question and objectives

The aim of this study is to investigate the reasons behind the lack of DT adoption in the AECO industry given the suggested lack of value propositions of DTs. Consequently, this research is motivated by the lack of a comprehensive identification of the actual value of DTs during the life cycle of built assets. Towards tackling the above problem, the proposed research question is *what is the value realized through the use of DTs in AECO projects?*

To tackle this question, the objectives of this study are threefold: (1) Investigating the value of DTs by identifying the associated benefits and costs with their use; (2) assessing the availability of empirical evidence supporting the claim of those benefits and costs; and (3) the identification of the life cycle stages during which value can be materialized.

Research background

Firstly, a clear boundary should be drawn between the difference of value and benefits. The two terms have been used interchangeably in literature (Laursen and Svejvig, 2016) while benefits are only a component of the total value. In basic terms, the realized value equates to the benefits less the cost depleted (Morris, 2013; Project Management Institute, 2019). Thus, the true value of an asset or a system involves an interplay between the accrued benefits and incurred costs. Benefits are those advantages provided to stakeholders (Ward and Daniel, 2006) that should be perceived by some stakeholders as a positive outcome (Bradley, 2010). The benefits derived from Information System (IS) investments can be either tangible, semi-tangible or intangible (Becerik-Gerber and Rice, 2009). Tangible and semi-tangible benefits are quantifiable while intangible benefits are non-quantifiable. Costs can be classified as direct or indirect.

One of the main desired benefits of the DT concept application in construction projects is the creation of value to deliver better project outcomes. Value creation has been denoted to be one of the nine fundamental properties of a DT as per the general concepts described in the Gemini Principles (Bolton et al., 2018). Within different architectures proposed for DTs (Ferré-Bigorra, Casals and Gangolells, 2022; Lu et al., 2020), the service layer is where DTs can deliver value to different stakeholders. At this layer, the user can interact with the system, and different functions can be deployed such as energy management and space utilization (Lu et al., 2020). During the design phase, DTs have the potential to reduce the possibility of rework, and deliver sustainable outcomes (Opoku et al., 2021). Construction costs can be minimized as well while improving the quality of deliverables (Opoku et al., 2021). Better decision making and predictive maintenance were some potential benefits suggested during the operation and maintenance phase (Khajavi et al., 2019). The literature was not very clear on demonstrating the cost behind the utilization of DTs. Costs were generally represented as barriers to adoption where difficulties in initial investments were stated (Madni, Madni and Lucero, 2019; Opoku et al., 2021).

For those reasons, the next section of this study will focus on collecting and analyzing literature sources related to the value of DTs realized by different stakeholders in the AECO industry. The method used for systematic collection of literature will be outlined, followed by the frameworks used for benefits and costs identification.

Methods and tools

To address the outlined research question, this paper will utilize a systematic review to organize and analyze the literature production in the realm of DT value delivery. This collation of evidence will follow the guidelines of the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) (Page et al., 2021).

Scopus and Web of Science (WoS), well regarded as robust academic databases, were used for article identification. The search was carried out using the title/abstract/keywords field with three blocks of keywords:

(1) Digital twins: (digital twin*);
(2) Value: ("cost-benefit" OR "benefit-cost" OR "cost-effectiveness" OR "return on investment" OR "financial*" OR "feasibility" OR "value for money" OR cost* OR benefit* OR value* OR "business case");
(3) AECO industry: (aec* OR "construction industry" OR "built environment").

Given the nascence of DT research, and to conduct a comprehensive review of the literature, no filters were added for the date range. The results were filtered for journal articles and the search returned 99 articles in Scopus, and 87 in WoS.

The identification step was followed by the screening stage to assess the relevance of obtained articles. Initially, the obtained records were imported into a reference management software to remove duplicate records. Only articles written in English were retained for further screening. An initial screening of the abstracts and titles of the retrieved articles was followed to ensure that the focus of the publications was on DTs within the Built Environment. At this step, 45 articles were retained for a comprehensive review based on the eligibility criteria defined in Table 1 following which 12 articles were deemed eligible for the systematic review as shown in Figure 1.

Table 1: Inclusion and exclusion criteria

	Inclusion criteria	Exclusion criteria
Methodology	Case study, Survey, Experiment	Literature-based only
Focus	Studies providing some empirical or theoretical evidence regarding the potential benefits or costs of DTs	No identification or evaluation of DTs' benefits or costs
Depth	A comprehensive application of a DT	Study focusing on a particular technology rather than a comprehensive DT implementation

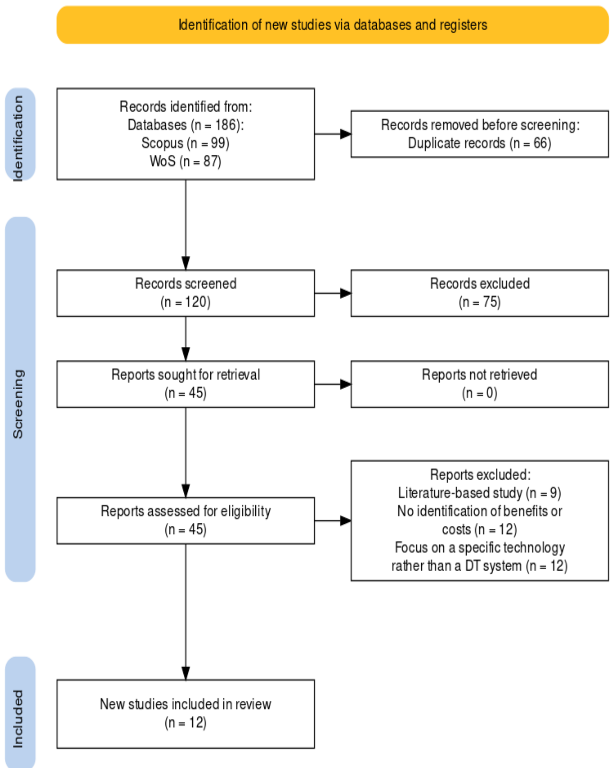

Figure 1: PRISMA screening process. Adapted from Haddaway et al. (2022).

Benefits and costs identification

The Centre for Digital Built Britain (CDBB) has adopted the Five Capitals Model developed by Porrit (2007) to profile the value of DTs (CDBB, 2021). This model has been developed to assess sustainable developments, and it is composed of five value categories namely: Natural, Social, Human, Manufactured and Financial capital. Natural capital includes the natural resources that are fused to provide goods and services. The Social capital includes the systems and institutions that help the Human capital work more productively when working collectively rather than in isolation. Manufactured capital is comprised of the assets that contribute to the production process and not the output. Financial capital is what allows the earlier categories to be traded and owned, and it encompasses their economic benefits and different costs.

To assess the value of DTs, their different benefits will be first identified from the collected literature and classified according to their tangibility. Tangible benefits can be easily quantified, while intangible benefits require a qualitative assessment that would subsequently impact one or more of the tangible benefits by means of a factor or percentage (Irani and Love, 2002). This classification of benefits was adopted by Irani and Love (2002) to develop a frame of reference for Information technology/ Information Systems (IT/IS) investment evaluation. It should be noted that this framework did not provide a taxonomy of IT/IS benefits, and hence it will be used as a reference to identify and cluster benefits. The focus of this process will be on benefits that are tangible and hence quantifiable.

For the costs, the identification process will follow the cost taxonomy developed by Irani, Ghoneim and Love (2006). The costs are classified as direct or indirect. Direct costs are associated with the use of technology components, while indirect costs capture that related to the organization and people dimension. This classification embodies both the technical and social components of a socio-technical system (Bostrom and Heinen, 1977) which could be deemed suitable for capturing a holistic DT utilization. Furthermore, this scope can capture all value categories highlighted in the Five Capitals Model (Porrit, 2007).

Investigation method of studies

Bakis, Kagioglou and Aouad (2006) outlined three main empirical investigation methods for evaluating the benefits of new technologies implementation as case studies, experiments, and surveys. Case studies were identified as the most robust of the three as they place the most emphasis on the context of the realized benefits. Experiments and surveys lack an emphasis on this context where the former imposes control factors for replication, while the latter does not depict how the benefits were created. Additionally, Hakimi et al. (2023) emphasized the need for conducting case studies to prove the business value of DT implementation.

The investigation method used in the selected articles will be highlighted. Articles using more than one investigation method will be highlighted as well. Finally, a further metric will be added to classify whether the study presented some quantifiable findings or not.

Results

Bibliometrics

To understand the broader research trends of DT publications, some quantitative bibliometric analysis was conducted on the 45 articles that were assessed for eligibility. Figure 2 illustrates an overall increasing trend in DT publications over the years.

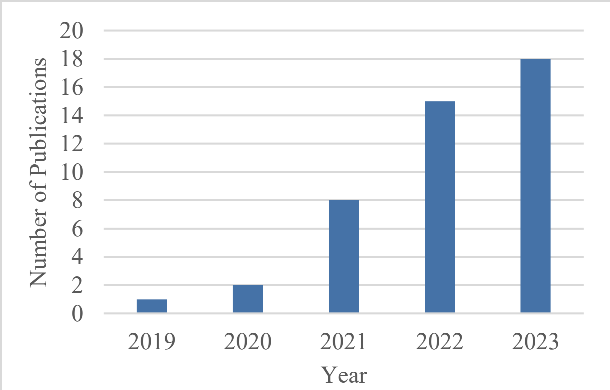

Figure 2: Bar chart showing the number of publications per year.

Based on a minimum number of two occurrences, a co-occurrence for author keywords was created as shown in Figure 3. In total, there were 24 occurrences where digital twins were the most common. There were no clusters for any of the *value* block keywords while the *AECO* industry's keywords appeared near the digital twin's cluster.

Content analysis

The classification of the selected twelve articles is illustrated in Table 2. Most of the studies followed a case study approach with only two of them employing more than one case study. Surveys were only used in three studies, and only one experiment was carried out. Four articles, adopting a case study approach, demonstrated some quantifiable benefits or costs from the use of a DT (Greif, Stein and Flath, 2020; Lin and Cheung, 2020; Love and Matthews, 2019; Zhang et al., 2023)

After reviewing the collected articles, a total of nineteen clusters of benefits were identified as illustrated in Table 3. Different benefits were matched to one cluster despite having different designations in different studies. For instance, increased transparency of information (Ammar et al., 2022), and transparency and data reliability (Esmaeili and Simeone, 2023) were matched to improved information management. The most common benefit was better environmental management followed by improved maintenance. Five other benefits were cited three times while the remaining were cited only once. Some of the presumed benefits were not matched to either of the

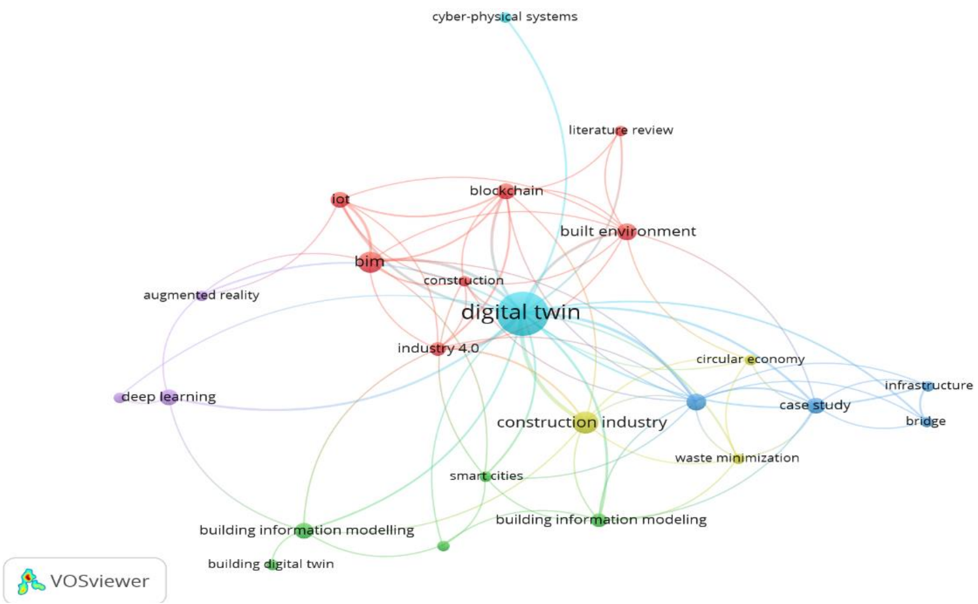

Figure 3: Author keyword co-occurrence map.

suggested benefits in Table 3 as they were essentially applications with different potential benefits but not benefits per se. For instance, Ammar et al. (2022) and Love and Matthews (2019) identified real-time reporting as a benefit while it could lead to other benefits that could be matched to more than one of the benefit clusters.

As for the benefits demonstrating some quantifiable findings, the study conducted by Greif, Stein and Flath (2020) presented a potential cost reduction of 25% in truck costs during silo movements between sites and plant. Another case study focusing on building heritage preservation demonstrated Indoor Air Quality (IAQ) improvements by an average of 9% and 1.2% for a restaurant and an exhibition room, respectively (Zhang et al., 2023). Love and Matthews (2019) illustrated different benefits across several case examples. In an Iron Ore Mine, the studied benefits were reported to result in a reduction cost of 94.25% in documentation cost. The time to produce a drawing was reduced to 2 hours from 40 hours with the use of a DT instead of a traditional Computer-aided Design (CAD) approach. Furthermore, the time required to address Request for Information (RFI) documents can be reduced by 91.67% person-hours in addition to improving the overall information management process of documents. The next case was a Magnetite Iron Ore Processing Plant, and the findings suggested an overall improvement in the information management process. This improvement has led to an improved site management since that design information was directly available for personnel on site. An improvement in installation efficiency as well as a reduction in cabling wastage were also reported, which suggests the delivery of an improved output.

In their next case of an Oil Refinery, improved information management, and improved site management were also reported. Monitoring the progress of person-hours worked on site has improved resource management. The DT was also reported to ensure asset integrity, which suggests an improved output. In their final study of a Rail project, there was a better handover of data from the construction phase to the operation and maintenance. DTs have also demonstrated their effectiveness in digital asset management.

Regarding the costs identified, only three publications outlined some relevant findings. Ammar et al. (2022) identified (1) Data understanding, preparation and usage, (2) Costs of implementation, and (3) Social costs, and it was the only source that identified indirect costs. Esmaeili and Simeone (2023) outlined data collection, platform and interoperability costs. Lin and Cheung (2020) highlighted the hardware cost, and it was the only reference that provided some minor quantification for the cost of wireless sensor networks used.

With respect to the life cycle stage of the studies, the operation and maintenance phase was the most common followed by the construction phase as illustrated in Figure 4. The benefits during the decommissioning phase were only demonstrated once.

Discussion and conclusions

This study has provided an overview on the realized value of DTs, based on empirical evidence, by identifying the associated benefits realized through their use. Different academic literature sources were retrieved from several databases to identify such. The findings demonstrated some benefits such as better environmental management and improved maintenance which were the most suggested benefits of this technology. Initial hardware costs, data infrastructure and handling were identified as the main cost elements. The findings suggest that the benefits of this concept can span across the whole life cycle of an asset. Most of the tested benefits were demonstrated during the operation and maintenance yet this finding does not suggest that this is the phase where stakeholders can realize most of the DTs' value. None of the studies presenting quantifiable findings investigated the benefits of DTs during the decommissioning phase.

From the selected articles, the first was published in 2019 which could suggest the impact of the Gemini principles (Bolton et al., 2018) in publicizing the value creation capabilities of DTs. The results, however, demonstrated a lack of research inquiries investigating the value realized with the use of DTs which is supported by the lack of author keywords related to value. There were also no studies providing a comprehensive record of the value realized by DTs. It was observed that all studies have either focused on benefits or costs, but not both. Other investigations focused on application areas only without providing an integral assessment of value.

Love and Matthews (2019) demonstrated some quantifiable findings in their study with respect to the benefits realized. The case examples used in this study included both vertical (building) and horizontal (infrastructure) projects which could suggest the varied applications of DTs in the AECO industry. The publication date of their paper, however, implied an early development stage for DTs in both the industry and academia, and hence their focus was on a System Information Model that can enable a DT. They also focused on providing an account of some benefits without extending appreciation to the costs involved.

Table 3: Benefits and their frequency in articles.

Benefit	References	No. of references
Better environmental management	Lin and Cheung (2020) Meng, Das and Meng (2023) Shahzad et al. (2022) Tagliabue et al. (2021) Zhang et al. (2023)	5

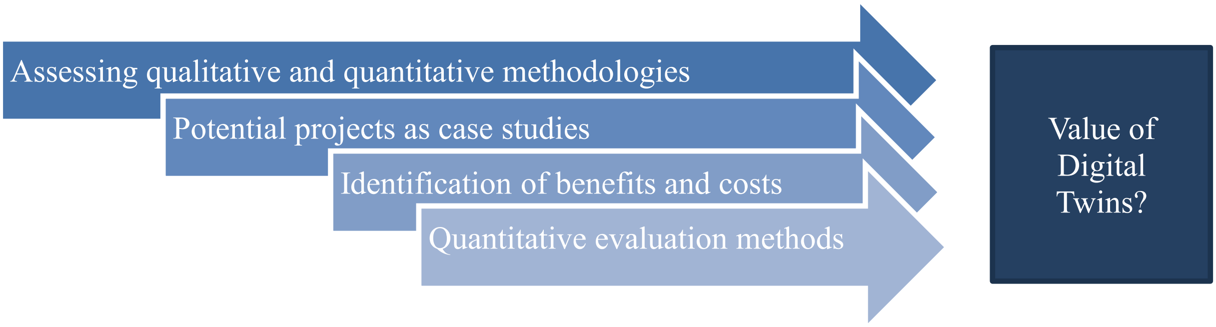

Figure 5: Research agenda.

In general, most of the studies did not present quantifiable findings which are the most sought after by practitioners when building a business case for additional investments. There was also some misclassification of benefits as an enabler of other benefits, with different designations used by different authors. The demonstration of quantifiable costs was even more limited than those of benefits. Empirical evidence coupled with quantifiable findings was only presented in four articles. This implies the need for a comprehensive assessment of the value delivered by DTs based on empirical evidence. A comprehensive cost-benefit analysis, or other quantitative evaluation methods, are recommended to tackle this issue, or to potentially identify the limitations of DTs. Further assessment of the different quantitative appraisal methods for DT investment should be conducted to recommend the most suitable one. It is also recommended to conduct research to develop a benefit and cost taxonomies for DTs to assess the viability of this innovative system. The suggested lack of DT adoption could be related to its high cost of implementation or upfront investment. This requires further appreciation to the barriers to entry experienced by enterprises at both an organizational and people level.

One limitation of this study was the adoption of IS/IT-investment evaluation frameworks due to the lack of available DT-cost or benefit taxonomies. The used framework was not prescriptive and the development of a framework with defined benefits and taxonomy can lead to a more robust identification of value constituents. Another limitation was the lack of mapping the relationship and interdependencies between different clusters of benefits. Future studies could develop a stock and flow diagram to capture any interdependencies which would ultimately lead to more refined benefit clusters.

Moving forward with this study, the research agenda will extend this theoretical framework by investigating the suitable methodologies for assessing the value of DTs in the AECO industry as illustrated in Figure 5. The findings of this study have already suggested that case studies are robust for assessing the value of new technologies, and this method would follow a qualitative inquiry. Other potential methods to assess this problem include quantitative evaluation techniques such as Cost-Benefit Analysis or Multi-Criteria Decision Analysis. In either case, the theoretical insights obtained from case studies will inform the design of the quantitative assessment.

By drawing on both qualitative and quantitative evidence, this ongoing research could result in a comprehensive analysis of the value problem of DTs. The results obtained from this study will be used to validate the outcome of the primary research. By conducting this research, valuable insights could be recommended to various stakeholders in the AECO industry including practitioners and policymakers. Furthermore, the primary research could hold potential academic implications, enriching the existing knowledge base.

Abstract

The construction industry increasingly recognizes the potential benefits of cyber-physical systems, particularly Digital Twin (DT) technology, within the framework of Industry 4.0 and Construction 4.0. However, there remains a lack of clarity regarding the specific contributions of DT to the construction sector, often conflated with Building Information Modeling (BIM). This paper aims to address this ambiguity by conducting a historical review of DTs, delineating their key features, and elucidating the opportunities they offer throughout the stages of constructed facilities' life. Additionally, this paper outlines potential research trajectories and practical applications for leveraging DTs to enhance construction project delivery.

Introduction

We have experienced technological developments and applications in the construction industry in recent years. The construction industry is taking advantage of the wide range of technologies to facilitate digitalization and automation, enabling the integration of the construction processes at all value chain phases, resulting in the term 'Construction 4.0' (Oesterreich and Teuteberg, 2016). Construction 4.0 is attributed to Industry 4.0 which focuses on the seamless generation, analysis, and communication of data to enable smart manufacturing (Perrier et al, 2020). However, the construction industry's adoption of digitalization is still low, particularly in the area of Digital Twin which played a huge role in realizing Industry 4.0 (Brilakis et al, 2019). However, the intent is to use a wide range of smart technologies to digitalize and automate construction processes and activities. This is done to ensure a reduction in construction costs, more accurately controlled construction activities, and time savings.

Several systems and technologies have been determined to contribute to the digitalization and automation of the construction industry. For Example, cyber-physical systems to plan and monitor mobile cranes on site (Kan et al, 2018), construction robots (Bock & Linner, 2016), and digital twin (DT) for healthcare facilities management (Madubuike & Anumba, 2022). Technological development is all attributed to enabling and ensuring that construction activities are carried out efficiently and easily. The construction industry has experienced significant project time and cost savings due to important technological developments that have improved construction operations (Son et al., 2010). Digitalizing the construction industry entails using smart technologies, systems, or data to convert physical models and tasks to virtual models and tasks, enabled by machines or robots.

This paper investigates the extent to which Digital Twin is applicable for enhanced construction project delivery. It focuses on how DT can be applied in all phases of construction projects including design, construction, operation and maintenance, and decommissioning or demolition for enhanced project delivery. To achieve this, the paper covers the following: background to construction 4.0, DT in the construction project delivery process, key features of DT and its roles in the different project delivery stages, discussions centered on characteristics of construction problems amenable to DT, construction use cases, and the potential benefits of DT application in construction. It identifies salient points in the findings and highlights future research areas.

Construction 4.0

Background to Industry 4.0

The manufacturing industry is one of the oldest and has gone through several stages seeking improvement (Madubuike et al., 2022). It has moved from Industry 1.0 to Industry 4.0 in line with the phases of the industrial revolution. The breakdown of the various phases is as follows and shown in Figure 1:

- Industry 1.0 brought about the steam engine,
- Industry 2.0 saw the assembly line concept to reduce manufacturing lead time,
- Industry 3.0 embraced computer-integrated manufacturing which replaced labor, and
- Industry 4.0 employed digitalization and automation to ensure smart manufacturing (Roy et al., 2020).

Industry 4.0 has been made possible due to many great technological and scientific advances in the 21st century. The introduction and use of computers, the Internet of Things, and cyber-physical systems contributed to the emergence of Industry 4.0 (Forcael et al., 2020). The emergence of Industry 4.0 has also brought about progress in the construction industry resulting in the term 'Construction 4.0', which is primarily based on utilizing and integrating four key concepts: digital data, automation, connectivity, and digital access to enable the digitalization of the construction industry (Berger, 2016). The current trend in technological advancement supports the enablement of Construction 4.0 which, if properly considered, would meet the standards of Industry 4.0.

Towards Construction 4.0

The construction industry is characterized by complex and peculiar features such as the nature of projects, interest in technological investments, and the nature of sites which may make it difficult to implement digitalization or automation. Despite these complexities, the construction industry has experienced some increase in technology adoption, which is enabling the implementation of the concept of Construction 4.0. There is still no consensus on the definition of the concept of 'Construction 4.0'. Similar to DT, the definition of Construction 4.0 depends on researchers and its application. However, it centers around a decentralized connection between physical space and cyberspace using ubiquitous connectivity (Berger, 2016). However, Perrier et al. (2020) opined that Construction 4.0 is not limited to existing and new technologies but also implies using real-time data to transform project management processes for smart decision-making purposes. The manufacturing industry has implemented the concept of 'Industry 4.0' which has given guidance to the construction industry on the implementation of 'Construction 4.0'. Construction 4.0 is seen as an innovative construction management technique that allows for the creation of a smart construction site as driven by Industry 4.0 (Perrier et al., 2020). However, this definition focuses on a 'smart construction site' and does not integrate the project management process which is also a key part of the construction process.

Consequently, to integrate all aspects of construction, this study defines Construction 4.0 as a smart construction technique that integrates existing and new technologies including real-time data to transform and automate the project management and construction process thereby ensuring smart decision-making that leads to efficient project delivery. The emergence of technologies amenable to construction (Madubuike et al., 2022) is paving the way for the implementation of Construction 4.0. Although there is no single technology that can develop a Construction 4.0 environment, the combination of various technologies is considered vital. Perrier et al. (2020) identified different technologies categorized under 7 groups that could be combined to create Construction 4.0. The 7 technology groups include *Group 1* (BIM), *Group 2* (Monitoring – GIS, materials tracking technologies, just-in-time (RFID), and life cycle management), *Group 3* (artificial intelligence), *Group 4* (Data Science – cloud computing, data transfer, and data protection), *Group 5* (Modeling Systems), *Group 6* (Digital Fabrication – robots and autonomous machines), and *Group 7* (Prefabrication). Some of the listed technologies also combine to develop the Digital Twin technology which is still at its nascent stage and can provide a good basis for implementing construction 4.0.

Place of Digital Twins in Construction 4.0

Digital Twinning involves the use of smart enabling technologies to virtually represent a physical asset by obtaining real-time updates and effect bidirectional coordination such that the virtual model closely or accurately represents the physical asset (Madubuike & Anumba, 2023). There is no single definition for a Digital Twin, as each definition depends on the purpose for which the DT is designed. DT combines smart technologies and data sciences similar to Construction 4.0. While DT is centered on creating a digital replica that closely represents the physical assets including all its instances, Construction 4.0 focuses on automating the construction and project management processes, ensuring smart decisions and efficient construction project delivery. In much the same way as cyber-physical systems are a critical component of Industry 4.0; they are also very important in realizing the vision of Construction 4.0.

Digital Twin can be regarded as a key component of Construction 4.0, as all DT enabling technologies are required for Construction 4.0. This helps to delineate the relationship between DT and Construction 4.0 and demonstrate how DT will facilitate the implementation of Construction 4.0. For this study, DT has been defined as the virtual representation of a physical asset using DT-enabling technologies such as sensors, communication networks, and 3D models to obtain real-time updates and effect bi-directional coordination such that the virtual model represents a replica of the physical asset in all instances.

Digital Twins in the Construction Project Delivery Process

Historical Perspective

While various literature has it that DT was developed in 2003, the origins of digital twin technology are traced back to the 1960s (Boschert et al, 2018; Madubuike et al, 2020). The NASA project in 1960 started with the twin concept where two physical space vehicles were created with one called 'the twin' which was placed on Earth to mirror the other vehicle in space (Boschert et al, 2018; Zhuang et al, 2018). However, in the NASA project, the 'digital' aspect was not included at that time. Subsequently, Micheal Grieves introduced the DT concept in his product lifecycle management course in 2003 (Grieves, 2014). Consequently, DT has been mentioned and applied in different fields and industries such as aerospace (Tao et al, 2017), automotive (Lahoti, 2021), energy (Sivalingam et al, 2018), healthcare (Laaki et al,

2019), telecommunications (He et al, 2017), and manufacturing (Roy et al, 2020). Additionally, the growth of the DT concept is beginning to be integrated into the different aspects of construction.
The flexibility in the DT application could be attributed to its features of real-time updates, bi-directional coordination, and the inclusion of digital models for its functionality. Keen (2019) identified that DT can take advantage of BIM and 3D models including other essential contractual information to create digital twin models of buildings using sensors and other smart technologies. Figure 1 provides the historical milestones with DT applications in various fields.

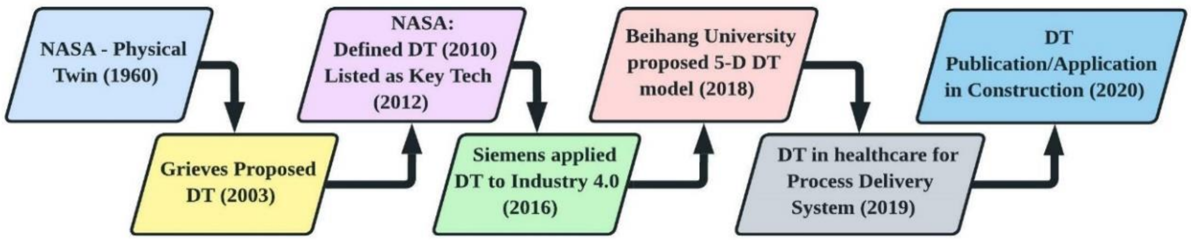

Figure 1: DT Historical Milestones (Adapted from Madubuike et al, 2020).

Key Features of DTs

DT has been identified as a promising state-of-the-art digital platform that enables the management and monitoring of physical assets (Martinez et al, 2018). It has key features that make it applicable to various fields and industrial sectors by representing the physical asset (including its operational changes) through appropriate sensors and communication platforms. Some key features of DT include a 3D digital model for visualization, real-time updates, predictive, and monitoring features, and bi-directional coordination (Madni et al, 2019).
Additionally, studies have developed DT system architectures that explain the relationship between the DT key features (He et al, 2018; Laaki et al, 2019; Madubuike & Anumba, 2022). One of the system architectures was used to develop a DT-based healthcare facilities management (Madubuike & Anumba, 2022; Madubuike et al, 2023). The system architecture was developed with six layers including the physical, sensing, application, communication, device, and virtual prototype layers. These different layers were integrated to prove the identified key features of DT.

Key Construction Applications of DT

The versatility of DT has made its application in various industries possible (Madubuike et al, 2022). Some DT applications in construction include the use of DT to monitor construction work progress (Braun et al, 2018), and using DT to monitor the state of bridges (Sacks et al, 2018). Another DT use case is Singapore's Frasers Tower constructed by Bentley Systems and Schneider Electric, providing a connected workplace for DT purposes (BIM News, 2020). DT for monitoring the state of a bridge (Sacks et al, 2018) and a DT-based system for healthcare facilities management (Madubuike & Anumba, 2021). The DT Hub to promote DT best practices for infrastructure and provide a testbed for the information management framework for the built environment that will enable future National Digital Twin (CDBB, 2020) is a huge step by Britain to provide a consensus view on the implementation of DT. Another DT implementation in construction includes DT for improved healthcare facilities management by monitoring indoor air quality (Madubuike & Anumba, 2023). Although publications on DT have focused more on the operations and maintenance phase, there are still opportunities in the construction phase.

DT Role at Construction Project Delivery Stages

The versatility of DT is seen in its applicability to different fields and industries including the construction industry. However, DT application in the construction industry is still in its nascent stage. Although publications on cyber-physical systems in construction date back to 2009, DT publications in the construction industry started in 2019 with just 2 publications which later grew to 17 in 2021 according to the Web of Science (Madubuike et al, 2022). There is an increasing volume of literature on DT applications in the construction industry. However, much of the literature on DT in construction focuses on concept proposal and prototype development with fewer cases of industry implementation. This shows that the construction industry is still exploring the best application areas for DT. The applicability of DT to the 4 high-level stages of the construction project delivery process is discussed below:

Design

The design stage is one of the earlier stages of any construction project where the planning and design of the project to be constructed are conducted. The design stage is very important as it defines the product and the associated processes needed to bring it to fruition. In Latin American countries, it was determined that 20-25% of the construction period is lost due to design deficiencies (Undurraga, 1996). Additionally, design changes during construction are responsible for the increase in project costs, delays, and in some cases, poor quality of work (Hindmarch, 2010). Several design management tools and techniques such as the Analytical Design Planning Technique (ADePT), Last Planner methodology, and Construction Design Change Management (CDCM) model have been identified (Hindmarch, 2010). However, these tools and techniques lack the essential feedback experience that would help avert any future change when construction begins. Consequently, DT can be used at the design stage to run 'what-if' simulations of real-life scenarios to ensure that most or all possible changes are fully considered at the design stage.

DT implementation at the design stage is currently being considered by construction sector companies embracing the growing trend in technology. This would entail ensuring that all requirements and conditions essential for DT implementation are considered at the design stage. It will ensure an effective and seamless integration of the digital model with the physical facility being constructed. Additionally, the use of VR and AR can be considered good tools while implementing DT in the design phase where project stakeholders can experience the 3D model and make all necessary observations and changes before construction. Negendahl (2015) proposed using 3D geometrical models to run building performance simulations (BPS) at the design stage to ensure buildability and effective building performance. Sacks et al (2018) and Brilakis et al (2019) proposed a geometrical digital twin in developing a design model. However, this was to develop digital models for already existing structures. A geometric digital model can be augmented with semantic information and is the first step to creating a digital twin (Brilakis et al, 2019). This model is then continuously updated with construction and operational data/information that enable it to adequately represent the physical facility and facilitate bi-directional coordination between the two.

Construction

The construction stage is an important phase of construction where all design ideas and plans are implemented. The construction phase is laden with complexities that may affect the adoption of modern technology. Some of the complexities include difficulty understanding the construction phase requirements and adopting modern technologies due to insufficient information (Shahrabi & Mohammadi, 2013; Anumba, 2000). However, DT has proven to be versatile and can be implemented at certain phases of the construction stage to ensure that projects are well constructed to meet the client's needs.

DT can be used to monitor construction work progress (Braun et al, 2018), and workers' productivity, and compare as-builts to the initial designs. DT can provide the opportunity for stakeholders to get involved in a project for site inspection even without being physically present. This can be possible using third-party applications that enable 3D/360-degree remote viewing. The creation and implementation of DT in the construction phase also depend on the available digital model or the Building Information Model (BIM), which contains the 3D geometric information necessary for DT creation.

One of the major purposes of every DT implementation is to create a digital model that truly represents the physical facility and enables real-time performance monitoring. Consequently, the digital model created at the design stage is developed further during construction to capture the actual as-built information, which is vital for the operations and maintenance stage.

Operation and Maintenance

The effective implementation of the design and construction stages would determine the outcome of the operation and maintenance phase. The operation and maintenance phase defines the building's performance and its lifecycle management. It is imperative that buildings or any other infrastructure should be designed and constructed with lifecycle management in mind. DT offers effective opportunities to monitor and manage facilities and ensure improved facilities' performance. The implementation of DT for the operations and maintenance stage should be considered at the inception stage (Grieves & Vickers, 2017).

DT implementation in the operation and maintenance phase has been considered by various studies. Some examples include the use of DT for bridge inspection (Sacks et al, 2018), DT for a connected workplace in one of the office towers in Singapore, and a DT-based system for healthcare facilities management (Madubuike & Anumba, 2021). These examples show that the implementation of DT in construction, particularly in the operation and maintenance phase, is beginning to grow. There are more prospects for DT implementation in the operation and maintenance phase, especially in monitoring the performance of key equipment and building components (Madubuike & Anumba, 2021; Madubuike, 2022; Asare, 2023; Kang & Mo, 2024).

Decommissioning/Demolition

Decommissioning/demolition is the last stage in the lifecycle of any constructed facility. It comes up when a facility has reached the end of its useful and economic life. Some important considerations before decommissioning and demolition include relevant components of the facility that could be salvaged given their current use/reuse value, ensuring that the demolition would not be harmful to the environment or surroundings, and the selection of the most appropriate techniques for the demolition (Anumba et al, 2008; Stevens, 2019). Currently, no study has addressed DT applicability with decommissioning or demolition. However, DT can be used to run demolition simulations of real-life scenarios to understand what better techniques to adopt and the possible effects of the techniques adopted. DT offers a range of benefits depending on what purpose it was created for.

Discussion

Bi-directional Coordination

Bi-directional coordination is the final of the DT features which enable information flow between the physical to digital model and vice versa. Figure 2 provides a proposed simple schematic representation for DT bi-directional coordination. The sensors obtain information from the physical asset which updates the DT platform and the controller. The controller detecting any anomaly in the data received, sends a control effort to the actuator. The actuator inputs a control signal that updates the physical asset. An example where this bi-directional coordination model can be applied would be in controlling systems within buildings such as the HVAC system and others.

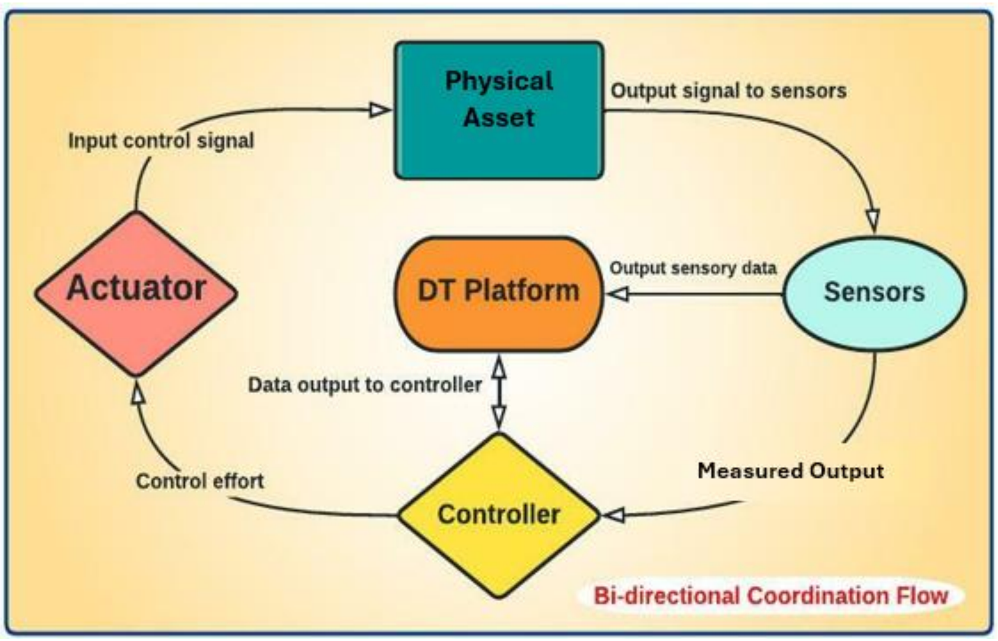

Figure 2: Schematic representation of DT Bi-directional Coordination.

Characteristics of Construction Problems Amenable to DT

The application of DT to the realization of construction 4.0 is still at the nascent stage due to the construction industry's slow adoption of emerging technologies. The construction industry (CI) is one of the major industries with unique and complex processes, interrelated activities, and high uncertainty levels. Consequently, no two similar construction projects are directly similar. This can be attributed to the volatile nature of the construction industry (Brilakis et al, 2019) which makes it difficult for the adoption of smart technology. Some of the characteristics of the CI include methods of procurement, a large number of small and informal contractors, fragmentation with too many stakeholders, no single regulatory authority, reliance on temporary skills, and cultural influence (Boadu et al, 2020). However, given the growing technological trend in the construction industry, some of the problems associated with these CI characteristics can be addressed through DT adoption t. The real-time monitoring feature of DT can be used to monitor construction work progress and construction workers, generating DT models of physical structures and enabling real-time updates and bi-directional coordination for the lifecycle performance of a facility (Braun et al., 2018; Brilakis et al., 2019).

DT Best Practices

DT has proven to be a fast-growing and versatile technology applicable in various fields. Given the versatility of DT, calls have been made to create DT best practices. Brilakis et al (2019) explored DT and its market while requesting its standardization for market demands. Other researchers have argued that its different protocols and standards affect the potential for DT standardization (Qi et al, 2019; Madubuike & Anumba, 2021). However, there has been some progress made in providing interoperability in DTs. Some of the DT best practices include the 3rd Generation Partnership Project (3GPP) for 5G communications for DT, oneM2M to standardize a service layer IoT platform, ISO/TC 184 for industrial data standards, ISO/IEEE for digital health data, and IEC TC65 for interoperability in the smart factory (Song & Le Gall, 2023). The creation of these best practices and standards may help improve DT adoption in construction which is characterized by complex and unique projects.

Potential Benefits of DT in Construction Project Delivery

DT offers several potential benefits that may be integrated into the various phases of a construction project. The potential benefits that DT has to offer in construction product delivery if properly implemented can be drawn from other fields and areas where DT has been successfully implemented. Understandably, construction project delivery (CPD) is guided by three major baselines – quality, cost, and schedule. The potential benefits of DT for construction project delivery can be weighed against these baselines. The following are DT potential benefits that can be attributed to CPD including automated progress monitoring, updated as-built drawings, safety monitoring, resource planning and logistics, optimization of equipment usage, quality assessment, monitoring and tracking of workers, monitoring of a facility, facilities management and operations, decision making and sustainable development (Madubuike & Anumba, 2022).

Conclusions

Digital Twin technology has shown flexibility and applicability in various industries particularly in the manufacturing industry leading to the emergence of Industry 4.0. Consequently, the construction industry has taken a cue from the emergence of Industry 4.0 to initiate the emergence of Construction 4.0. Similarly, Construction 4.0 adopts smart technology, digitalization, and automation to make smart decisions during the construction and operations of buildings and facilities. Although Construction 4.0 is yet to be actualized like Industry 4.0, studies show that DT application in construction is growing. This paper made efforts to discuss DT application in construction with a focus on the various stages of construction. DT applications in the design, construction, operations and maintenance, and decommissioning/demolition stages were discussed.

DT provides potential benefits to the various phases of construction which would ensure enhanced construction project delivery. In the design phase, DT can help in capturing as-built information that will fully represent the finished project. For the construction phase, it can be used to monitor project progress. During the operations and maintenance phase, DT can provide real-time updates to monitor facility performance. The use of DT to run simulations to salvage valuable building components and determine effects on the environment before demolition is another considerable benefit. In summary, DT helps in smart decision-making for improved construction project delivery.

The growing trend in smart technologies and DT studies in construction will help enhance construction project delivery through the DT approach. Understanding the concept, characteristics, and applicability of DT together with the characteristics of the construction industry amenable to DT are essential in improving construction project delivery through the DT approach. DT offers potential benefits in enhancing construction project delivery by ensuring cost reduction, avoiding design errors, minimizing delays during construction, monitoring construction progress, and real-time reporting on a facility's performance. These potential benefits of DT cut across the various stages of construction delivery. Future DT research can investigate in detail the implementation of DT at the various stages of the construction process highlighted in this paper.

BIM-GIS INTEGRATION THROUGH OPEN TOOLS

Eleonora Congiu[1], Emanuela Quaquero[1] and Giulia Rubiu[1]
[1]Department of Civil Environmental Engineering and Architecture (DICAAR), University of Cagliari, Cagliari, Italy

Abstract

The implementation of effective workflows based on a fully open BIM-GIS (Building Information Modelling-Geographic Information Systems) integration is still an unsolved topic. This is mainly due to the lack of freely available BIM authoring tools, as well as to still unfixed interoperability issues between software. In this context, this paper proposes a new methodology to effectively integrate BIM and GIS without using commercial tools and proprietary formats. The proposed workflow is enabled by the use of the add-on "BlenderBIM" for the free software "Blender", which allows to manage IFC (Industry Foundation Classes) models by updating non-geometric information through ".csv" files. Moreover, ".csv" files are also assumed as the main information exchange vehicle between BIM and GIS. The method is finally validated through an illustrative case study.

Introduction

Currently, the management of large building stocks is one of the most challenging activities which copes with many heterogeneous aspects and issues. In such a framework, the paper proposes a methodology capable of integrating different but strongly complementary tools, data, and information for a multiscale approach. It shows the first results of an ongoing research focused on the integration of BIM and GIS environments by taking advantage of open-source tools and non-proprietary data exchange formats. It is worth specifying that the herein proposed experimentation is part of a wider research concerning the implementation of an effective BIM-GIS integration in support of facility management of large building stocks (Congiu et al., 2024). However, the BIM-GIS workflow proposed in (Congiu et al., 2024) took advantage of open-source tools except for the BIM authoring. In this context, this contribution preliminarily attempts to replace the commercial BIM authoring in the original workflow (Congiu et al., 2024) by introducing BlenderBIM (*BlenderBIM Add-On*, n.d.) (an open-source BIM tool which is still in an unripe maturity level but really promising) and testing it through a simple abstract case study. In contrast to what has been mainly proposed in the literature concerning BIM-GIS integration so far, the methodology presented in this paper does not aim at transferring BIM data to the GIS platform. This unusual choice relies on the belief that it would be more advantageous to not wholly transfer integral BIM models into a GIS system firstly to prevent information redundancies and wastes, by keeping well distinct the two informative systems, as they have distinct purposes. Moreover, in the perspective of implementing an effective BIM-GIS integration to manage large building stocks, transferring into GIS a considerable amount of integral BIM models it would make GIS projects too large and extremely difficult to be managed. For this reason, only some necessary information (selected based on the specific application field of the BIM-GIS integration) to be handled at an urban scale should be considered to be shared between the two information systems. The work thus focuses on a bidirectional integration between the two informative systems, by linking them and allowing for an easy switch from one system database to the other. The experimental phase, reported in the final part of the paper, focuses on the validation process of the methodology developed by applying the proposed methodology to an illustrative case study.

Literature review

Open BIM workflows: use of the IFC

In accordance with the buildingSMART International definition, openBIM is intended as a collaborative vendor-neutral process, which has to ensure good interoperability, the use of open standards and workflows, reliability of data exchange flows, flexibility, collaboration and sustainability (buildingSMART International, n.d.). It is also worth remarking that the non-profit organization buildingSMART International is responsible for creating and adopting open international standards such as IFC (Industry Foundation Classes), bSDD (buildingSMART Data Dictionary), and BCF (BIM Collaboration Format) to promote a common language in data exchange. In particular, the IFC schema is a standardized, ISO-recognized (ISO 16739-1:2018), data model that codifies the identity, semantics, objects, related attribute and processes (buildingSMART International, n.d.). The IFC schema is currently used as an exchange data format. Some interoperability issues are therefore due to the fact that IFC is not treated as a native way of recording data created by specific BIM applications (Malewczyk, 2022). Unlike other BIM authoring tools, Malewczyk showed how the open-source add-on BlenderBIM for Blender (*Blender 4.0*, n.d.; *BlenderBIM Add-On*, n.d.) works as a true IFC authoring tool, thus minimizing the risk of data loss related to forced data conversions.

In this context, it is worth mentioning a comprehensive literature review on the openBIM domain, workflows, standards, software platforms, and tools, provided by Jiang et al. as an outcome of an accurate investigation of the most accredited databases (*e.g.* Scopus, Web of Science, Science Direct etc) (Jiang et al., 2019). Their study supplies indeed a detailed understanding of the progress status of OpenBIM research by also discussing the actual research gaps, including still unfixed critical issues in integrated BIM-GIS applications.

BIM-GIS integrated systems

Geospatial data in building planning and management play a very important role both because of their ability to integrate objects in a spatial context and to simplify all those operations involving a huge amount of information and data related to objects and to the territory in which these objects are located. Among geospatial data tools, Geographic Information Systems (GIS) play an important role, mainly due to their ability to perform spatial analysis and complex queries (Satria & Castro, 2016). In all cases where GIS involved a large building stock, the most crucial issue to be faced was to manage the huge amount of data and information that a building stock brings with itself. In the management of such data, a significant contribution has been made by BIM-GIS integration. GIS and BIM share similar features as they both manage spatial information but at different scales. Moretti et al. explored the combination of BIM and GIS and proposed a GeoBIM approach intended to im-prove digital Asset Management (AM), by especially focusing on outdoor and indoor condition assessment of the built environment. More specifically, Moretti et al. presented a GeoBIM model of the university Leonardo Campus of the Politecnico di Milano (Milan, Italy), by importing IFC models into a GIS environment in a 3D spatial data format by taking advantage of a specific commercial tool (FME workbench) (Moretti et al., 2021). Similarly, Sammartano et al. worked on a 3D City Model of Turin (Italy) to develop a digital twin of the city by taking advantage of a BIM-GIS integration with ArcGIS Pro (Sammartano et al., 2021a). Recently, Facility Management (FM) research is involving integrated BIM-GIS systems. FM is increasingly focused on finding solutions and tools to work at different scales more efficiently, from component, room, or building scale to spatial, regional, or national (Vankova et al., 2021). By way of example, Kang et Hong advanced a proposal of a software architecture based on an effective BIM-GIS integration using IFC and CityGML schemas, to specifically support FM (Kang & Hong, 2015). Vacca et al. showed the results of a research concerning the integration between BIM and 3D GIS, applied to a housing project in the city of Cagliari (Italy) (Vacca et al., 2018). Mangia et al. provided a comprehensive study, based on the analysis of the literature, concerning BIM-GIS integrated systems for managing large building stocks (Mangia et al., 2022). Meschini et al. focused their research on the development of an Asset Management System (ASM) for university building stocks by combining BIM and GIS with cognitive digital twins (Meschini, Accardo, et al., 2022; Meschini, Pellegrini, et al., 2022). Other interesting applications of GIS-BIM integration systems refer to the management of infrastructures such as highways (Zhao et al., 2019), airports (D'Amico et al., 2020), or railways. Wang et al. introduced a comprehensive study on the progress status of the research on BIM-GIS integration and its applications, by specifically underlining some still unsolved critical issues related to one-way IFC-to-CityGML conversion (Wang et al., 2019). The potential of BIM-GIS integration in several application fields was investigated by Liu et al. through an extensive state-of-the-art review (Liu et al., 2017). The research of Liu et al. revealed still unfixed issues related to information loss or corruption in data exchange, but also the potential of semantic web technologies as promising integration solution. Concluding, it can be stated that BIM-GIS integration still needs to be enhanced in terms of software interoperability, data exchange accuracy and use of open-source tools and datasets.

Methods and tools

In light of what has emerged from the literature review, it can be stated that although some available commercial tools allow to transfer BIM models into GIS maps by taking advantage of IFC-to-CityGML conversion (Sammartano et al., 2021b), a lack of BIM-GIS integrated workflows uniquely based on open-source tools is still noticeable. This evidence then motivated the present research which is focused on developing a new BIM-GIS integrated workflow by only taking advantage of open-source tools, add-ons and non-proprietary data formats (see Figure 1).

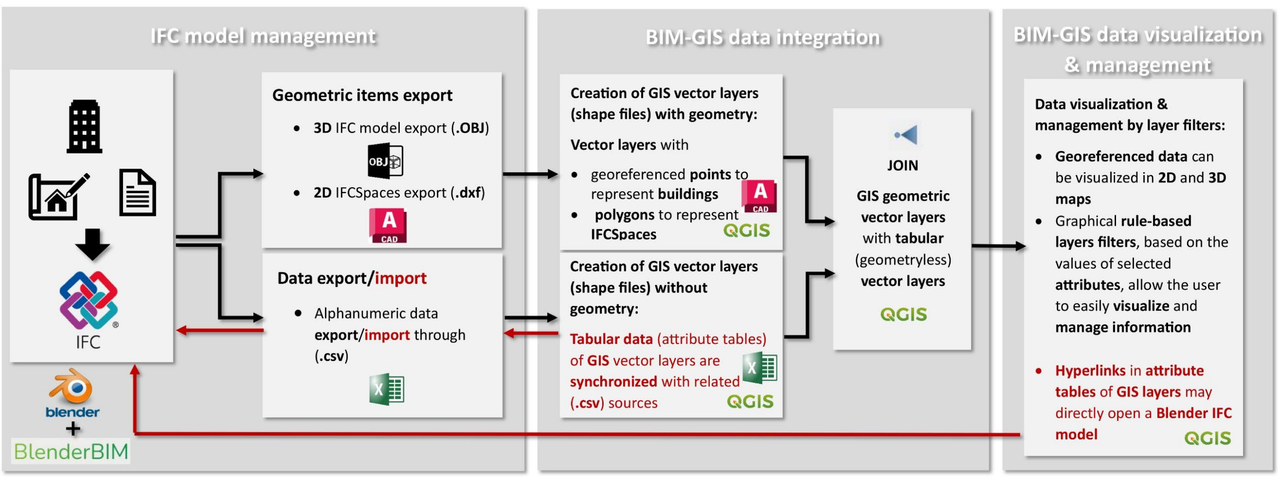

Figure 1.BIM-GIS integration workflow through open-source tools

It is also worth remarking that the proposed workflow is aimed at implementing an effective two-way integration between the two informative systems, by properly relating them and allowing for an easy switch from one system to the other, without transferring whole BIM databases into GIS maps. In this configuration, users can easily find the information which they require in the BIM model, at the scale of the specific building, and in the GIS model, at the scale of the large stock to which the specific building belongs. Moreover, the link between BIM and GIS models ensures that all the information, stored without copies or redundancies, is always updated and consequently reliable.

IFC model management through BlenderBIM

BlenderBIM (*BlenderBIM Add-On*, n.d.) is an add-on for the free but advanced modelling and rendering software Blender (*Blender 4.0*, n.d.). BlenderBIM provides an open-source IFC authoring platform which combines common abilities of modelling with additional scheduling, costing, simulating, and coordinating features. Blender and BlenderBIM add-on, unlike other BIM authoring programs, do not take advantage of object-oriented modelling tools. Blender tools allow the designer to create geometries whereas the BlenderBIM add-on allows the user to assign IfcClasses and related property sets to the modelled objects. BlenderBIM takes use of the IFC schema to classify geometries (Malewczyk, 2022). As shown in Figure 2, BlenderBIM easily allows a qualified user to model, edit and manage any sort of IFC object, as well as to manage IFC models deriving from a third BIM authoring tool. Therefore, BlenderBIM modelling is not object-oriented but rather IFC based. Elements classification and attributes are compliant with IFC standard, provided that a proper IFC class is assigned to each object. It can be therefore stated that, differing from other BIM authoring tools which use IFC standard to simply exchange data, BlenderBIM takes advantage of IFC as a native way to record information about the model (Malewczyk, 2022). As it is not among the goals of this research to transfer whole BIM models into GIS systems, the proposed workflow simply considers exporting IfcSpaces polygons as geometric items through the open-source add-on "ezdxf_exporter". The latter enables to export some selected IFC geometries to ".dxf" (Drawing Exchange Format) by properly setting custom properties of the exported layers. The choice of importing into GIS only BIM objects with simple geometry (*i.e.* IfcSpaces) is consistent with the aim of preliminarily testing the two-way effectiveness of the proposed BIM-GIS workflow on a simple dataset. In addition, IfcSpaces are suitable to be imported into a GIS environment as they can provide a proper .dxf geometric data source for a GIS shape file. The ".dxf" format is therefore assumed as the main exchange data vehicle between BIM and GIS for geometric entities. Moreover, the "Quality and Coordination" dialogue box of BlenderBIM provides a powerful "IFC-CSV Import/ Export panel" which enables two-way alphanumeric data exchange between the IFC model and ".csv" spreadsheets. This is the core of the proposed methodology as this BlenderBIM functionality allows to export IFC alphanumeric data to a ".csv" tabular form, as well as to directly update information stored in an IFC model by reimporting updated ".csv" tabular data back, provided that specific IFC selection queries are properly set up through specific panels ("Add Search Group" and "Add CSV Attribute"). It can be stated that the IFC model is the main repository of information in the proposed workflow. CSV files are used instead as main information exchange vehicle between BIM and GIS for non-geometric data.

BIM-GIS data integration

The aforementioned datasets (*i.e.* geometric and semantic IFC data) are then imported and managed through the open-source GIS software QGIS (Quantum Geographic Information System) (*QGIS*, n.d.). QGIS enables to develop a suitable GIS environment to handle spatial data. Both 2D and 3D georeferenced maps can be easily built by taking advantage of freely available raster and vector layers (provided that also elevation values are included in attributes), such as the following:

1. DTM (Digital Terrain Model) raster layer adopted as DEM (Digital Elevation Model) source for the terrain elevation (freely available for Sardinia Italian region (*SardegnaGeoportale – Aree tematiche*, n.d.)
2. orthophoto of the area
3. vector shape file of volumetric units of buildings from a geo-topographic database (GTDB) 1:2000, freely available for Sardinia Italian region (*SardegnaGeoportale – Aree tematiche*, n.d.).

2D and 3D queryable maps with basic topographic contents provide a suitable GIS-based environment to be efficiently integrated and linked with additional geometric and non-geometric information extracted from BIM models. As previously anticipated, the proposed BIM-GIS integration requires a clear distinction between geometric items and respective semantic attributes to be exported from BIM models to be transferred to the GIS environment. This clear separation is made necessary by the need to export selected geometric items to a ".dxf" format, which is suitable for generating GIS shape files but which, however, also involves the loss of most of information associated with the exported objects. Fortunately, non-geometric data associated with the selected IFC objects can be exported, in a tabular form, to a specific structured ".csv" file, which can supply a suitable data source of a GIS geometryless vector layer in the QGIS scene (by keeping information constantly and mutually synchronized). As shown in the flowchart in Figure 1, semantic alphanumeric information needs to be properly linked to the respective geometric objects in the GIS environment, without losing synchronization with the data source files. This operation is made possible by the QGIS "Joins Properties" layer tab (*QGIS*, n.d.), allowing the user to associate geometric features of the current layer (called "Target layer") with alphanumeric attributes from a geometryless layer (*i.e.* the "Join layer"). The layer "Joins Properties" functionality requires a "Join field" common to both layers to join, to accurately associate attributes of the "Join layer" with the "Target layer". In this regard, the proposed BIM-GIS integration approach provides for the assignment of IFC object names to ".dxf" layers during the related export, in order to create a suitable "join field" to allow subsequent "join" of attributes with the ".csv"-based geometryless layer in the QGIS environment. According to one of the main purposes of this research, in order to improve the bi-directionality on the BIM-GIS integration, the attribute tables of GIS layers may also include URL fields to hold specific hyperlinks to directly access useful additional files, like BIM models (*e.g.* BlenderBIM projects including IFC models).

BIM-GIS data visualization and management

The BIM-GIS workflow herein advanced, takes advantage of QGIS layer display features to enhance data visualization and management of the GeoBIM model. As previously anticipated, only IfcSpace objects have been assumed to be exported from BIM and imported into the GIS environment as 2D vector polygons. The latter may be also displayed on 3D maps as long as the related "height" values are set up as "extrusion" values in the layer 3D view tab. Also building "volume units" of the GTDB layer may be "extruded" on QGIS 3D maps to provide an effective graphical representation of urban contexts. In this regard, in order to make BIM-derived buildings more easily identifiable from the GIS urban context, a detailed 3D representation of that buildings, based on ".OBJ" geometries exported from the IFC authoring (*i.e.* BlenderBIM), may be associated with the related centroids (displayed as vector points in 2D maps) through the layer 3D view tab. In addition, QGIS rule-based filters for vector layers provide a powerful tool to ease data visualization and management in the herein advanced GeoBIM approach. More specifically, QGIS rule-based render options allow to discriminate features of a layer according to their at-tribute values by assigning them specific rendering settings. Filtering rules can be set up by taking advantage of a powerful SQL (Structured Query Language)-based "Query builder" dialog. In this regard, it is worth remarking the importance of setting up equally-named filters, based on the same rules, in both 2D and 3D view properties of layers, to ensure a perfect correspondence between 2D and 3D visualization of GIS maps. Unfortunately, QGIS does not enable to concurrently activate corresponding 2D and 3D render filters, so that users must therefore pay attention to activate 2D and 3D render options properly.

Workflow validation: a case study

The current section of this paper is aimed at validating the effectiveness of the BIM-GIS workflow, uniquely relying on the use of open-source tools and non-proprietary data formats, by simulating an illustrative example of data exchange, integration, visualization, and management, without employing a real case study. Therefore, as an example, a basic six-room house, developed on a single floor, has been modelled and adopted as an abstract illustrative case study to test the proposed BIM-GIS workflow. At this preliminary stage, the proposed methodology has not been implemented for a specific application field. For this reason, this work does not focus on specific information requirements nor on precise information sets to be transferred from BIM to GIS, as only some abstract test parameters have been used to validate the two-way effectiveness of the method.

IFC model management through BlenderBIM

A basic BIM model of the adopted application case study, managed through the IFC authoring add-on BlenderBIM, is shown in Figure 2. As highlighted through a specific object selection, the model includes six IfcSpaces, whose attributes are manageable through the "Attributes" sub-panel included in the related "Object Information" tab, available among the BIM setting tabs on the right section of the BlenderBIM Graphical User Interface (GUI). It can be noted that the "Name" attribute provides a univocal numeric code assigned to each IfcSpace, whereas the "LongName" is a textual parameter, conceived to store the space full name commonly including information on space end uses. The "GlobalId" attribute provides instead the 22-character encoded internal ID, which is automatically generated by the software for each IFC element. According to IFC standard, IfcSpaces are characterized by several property sets, among which it is worth mentioning the "Attributes" set (including the fundamental attributes cited above), the "Object Property Sets" (including various properties sub-groups), the "Object Quantity Sets" (containing all relevant parameters for quantity take-off), and so on. In addition to standard IFC attributes, IfcSpaces are herein also equipped with a custom IfcBoolean parameter, named "TestParameter", specifically created to be edited while performing experimental simulations of data exchange and management to assess strengths and weaknesses of the proposed BIM-GIS integration. In accordance with the proposed methodological workflow (Figure 1), IfcSpaces are exported to ".dxf" subject to properly set layer properties by assigning IfcSpace names to each respective exported layer through "ezdxf_exporter" add-on for Blender (see Figure 3). As far as IfcSpace alphanumeric data are concerned, some selected attributes, quantities and properties, including the aforementioned "TestParameter", are exported to a ".csv" tabular format (through the specific functionality of BlenderBIM), provided that specific IFC selection queries are defined properly (see Figure 4). It is worth remarking that the BlenderBIM sub-panel "Quality and Coordination" also allow to update the involved IFC data by simply uploading the updated version of the ".csv" file, as long as the same IFC selection queries used to export data are set up (Figure 4). This is fundamental to ensure a real bidirectional integration between BIM and GIS, as it will be shown more clearly at the next validation sections.

BIM-GIS data integration

In order to show an application of the proposed workflow, the IFC data extracted from the basic BIM-based model adopted as abstract case study, are properly imported into a GIS map. By way of example, a GIS map composed of a Digital Terrain Model, an orthophoto and the building "volume units" vector layer included in the Geo-topographic database (GTDB), all freely available as open geospatial data for the city of Cagliari, is generated. Thanks to the "elevation" attributes, it has been also possible to implement a 3D view of the map, thus providing both 2D and 3D representations of the urban context. Then, a georeferenced vector layer with geometric polygons is also added to the map as a shape file, by using the IfcSpaces ".dxf" file as data source. Consistently with the specific ".dxf" export setup herein adopted (described in the previous section), the "Layer" field in the attribute table holds the IfcSpace names.

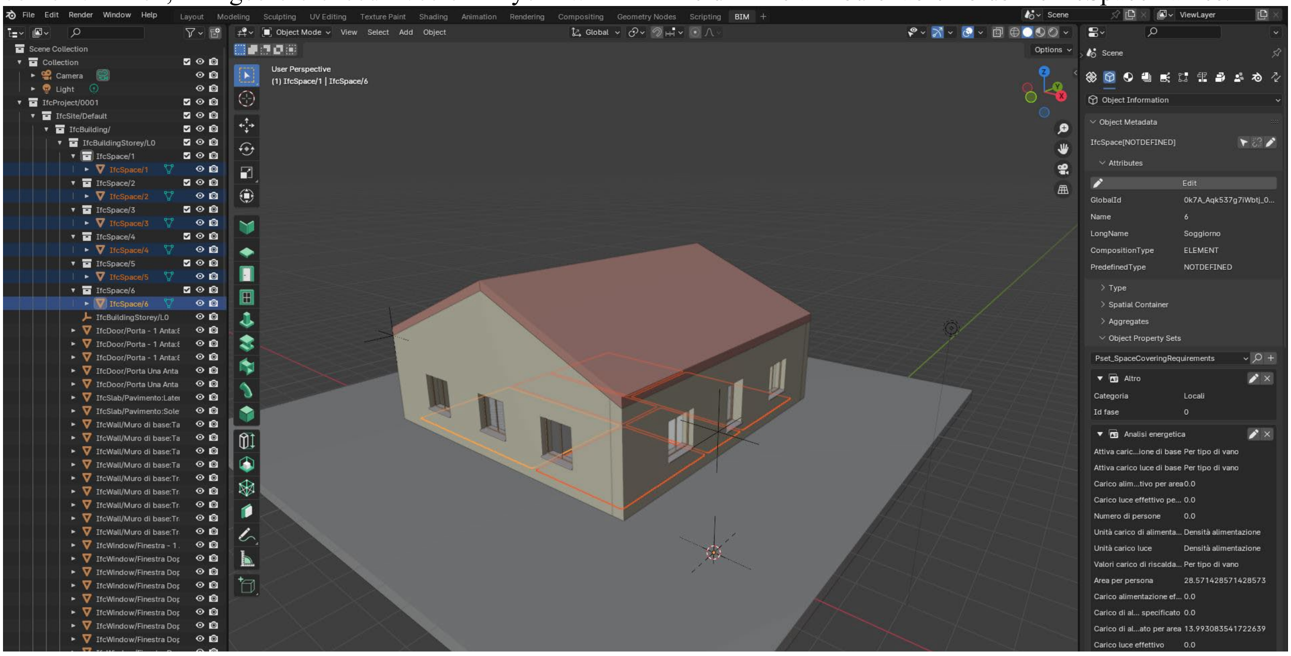

Figure 2: IFC model management through BlenderBIM (the illustrative case study)

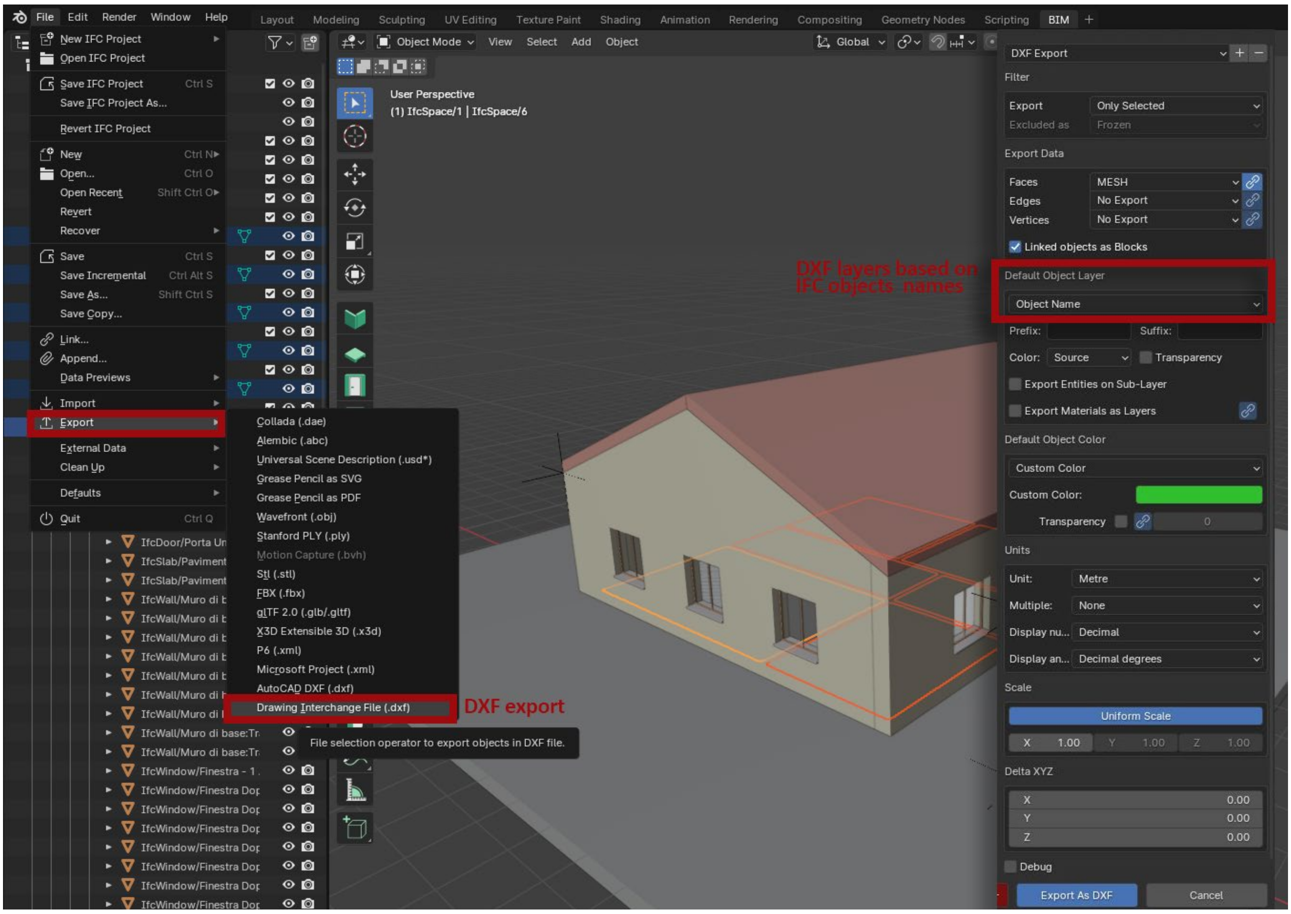

Figure 3: IfcSpaces export to .dxf (settings)

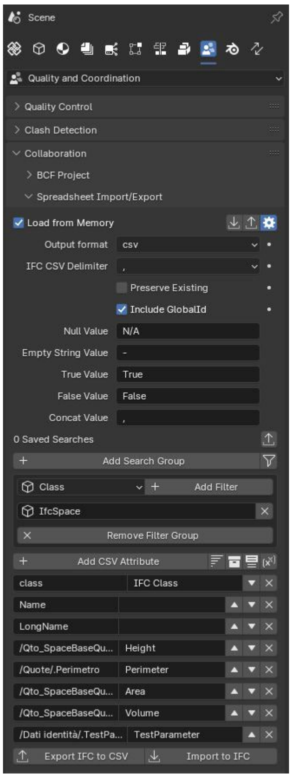

Figure 4: BlenderBIM – Export IFC to CSV and Import CSV to IFC settings for managing IfcSpaces data

The ".csv" table holding the additional alphanumeric IfcSpace data provides instead a suitable data source for a geometryless vector layer. In accordance with the advanced methodological approach, all fields of the csv-layer attribute table have been added to the attribute table of the IfcSpace layer including vector polygons by properly setting "Join Properties" of the "Target layer".

It is extremely important to underline that this operation ensures a join of attribute tables (see Figure 5) of the two involved layers without merging them, so as not to lose synchronization with the ".csv" data source of the geometry-less layer. Moreover, the IfcSpace "Name", shared by both attribute tables, provided a suitable "Join field" to correctly associate "IfcCSV" data with the respective IfcSpaces. It can be also noted that all attributes derived from the "Join layer" (*i.e.* the geometry-less csv-layer) are specifically marked with the prefix "IfcCSV_" in order to distinguish them from the layer original attributes instantly (see Figure 5). It should also be reported a critical issue related to the impossibility to directly edit attributes deriving from the "Join layer" through the attribute table of the "Target layer". Those attributes can be only managed by editing their original geometry-less layer synchronized with its ".csv" data source. Concluding, a vector layer including a georeferenced point, corresponding to the building footprint centroid, is added to the map, to hold general information about the building. To enhance the bi-directionality of the advanced BIM-GIS integration, the attribute table of the building centroid has been equipped with a special attribute (named "IFC model") to store an hyperlink (see Figure 6) to directly access the BlenderBIM project (holding the building IFC model).

BIM-GIS data visualization and management

As already declared, the GIS-based open-source tool QGIS is herein also adopted as GeoBIM data visualization and management platform. As far as data visualization is concerned, the IfcSpaces are graphically represented as vector polygons on the 2D map, whereas they are displayed as box objects on the 3D map, as long as the "IfcCSV_Height" attribute is assigned as extrusion value in the layer 3D view tab. Moreover, the building centroid is displayed as a georeferenced point on the map 2D view, whereas a detailed semi-transparent 3D hologram of the IFC model, based on the building ".OBJ" geometry exported from BlenderBIM, is associated as 3D model shape with the point 3D view properties (as shown in Figure 7). The detailed 3D hologram of the building is aimed at making BIM-derived buildings more easily identifiable from the box objects representing the built urban context. In Figure 7 some possible rule-based renderer filters are also shown. In this regard, the first exemplifying layer filters are simply based on the IfcSpace "names", which are also assigned as labels. The last two display filters, which are activated in Figure 7, are based on the Boolean value of the "IfcCSV_TestParameter", by assigning the red colour to "False" and the green colour to "True". It can be also noticed that the respective 2D and 3D layer filters, based on the same display rules, are simultaneously activated. Notwithstanding that the 3D view of the shown GeoBIM model could be beneficial in terms of objects visualization quality, the map 2D view turned out to be more easily accessible, queryable and manageable as informative system.

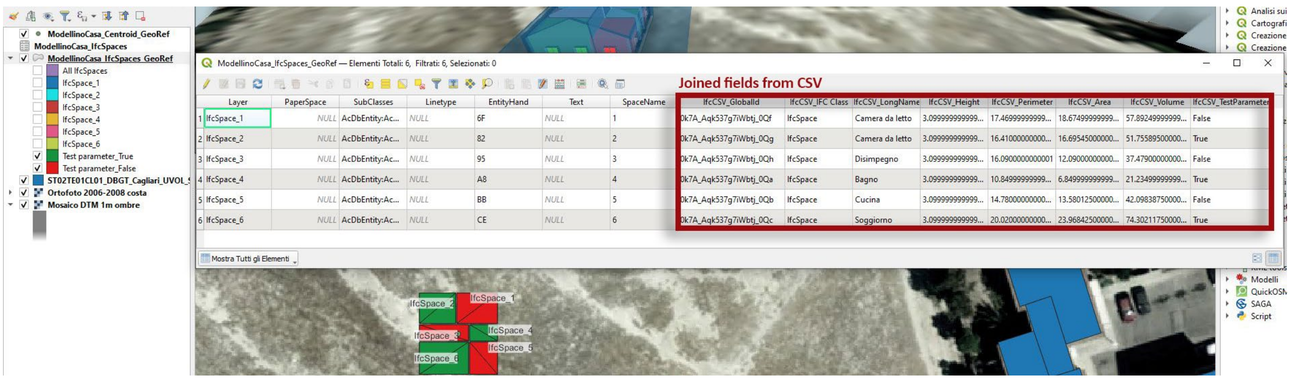

Figure 5: QGIS - Attributes table of the IfcSpaces (.dxf) polygons layer with additional "joined" attributes from .csv tabular data

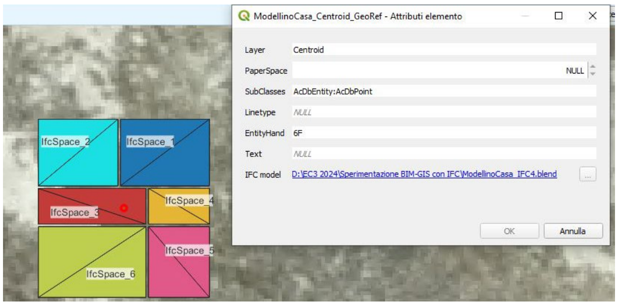

Figure 6: QGIS – IFC model hyperlink attribute

The conducted experimentation was finally concluded by validating the bidirectionality of the proposed BIM-GIS integration by first editing the "TestParameter" value of an IfcSpace on the GIS system and then successfully updating the IFC model by simply reimporting the related ".csv" file automatically updated thanks to data synchronization.

Conclusions

The integration of BIM and GIS methodologies and tools achieves high levels of effectiveness and efficiency in large building stock management. Starting from these premises, this paper shows the results of an ongoing research focused on the development of a methodological framework integrating BIM and GIS environments. The experimental phase conducted on an abstract illustrative case study allows the authors to highlight the strengths and weaknesses of the methodological framework developed. One of its strengths focuses on the exclusive use of open-source tools and open, international standards. This aspect is strictly bound with the important issues of interoperability, customization, verifiability, optimization, and low costs. The proposed methodology involves Blender-BIM, an open-source software that supports BIM approach, QGIS, an open-source software that allows users to manage geospatial information, and open standards like DXF and CSV. The work focuses on a bidirectional integration between the informative tools, by linking them and allowing for an easy switch from one system database to the other. Despite the benefits that this methodology offers, some potential critical issues have emerged. It is worth underlining the difficulties in data management and visualization through QGIS filters. Users must pay attention to manually activate both 2D and 3D display filters that are not synchronized although they are based on the same rules. Moreover, the 3D view is affected by some annoying selection bugs, which make it difficult to correctly query the 3D map. Another issue is the critical management of the attributes deriving from the "Join layer". These attributes can be only managed by editing their original geometry-less layer synchronized with its ".csv" data source. Finally, although the proposed workflow still needs to be improved and validated, it could be a solution to overcome some unfixed critical issues still affecting interoperability between commercial tools and enhance collaboration. Future work development will focus on the issues shown above.

DIGITAL TWINS IN BUILDING MANAGEMENT: BOOSTING EFFICIENCY IN RENEWABLE ENERGY COMMUNITIES

Giulia Rubiu [1], Emanuela Quaquero [1]
[1]University of Cagliari, Department of Civil Engineering, Environment and Architecture, Italy

Abstract

The study proposes a methodological approach for organizing, storing, and handling diverse data across disciplines using digital systems structured on the internet with a multi-level strategy. This workflow follows traditional knowledge process steps, storing and organizing outcomes in a unified web-based model using pre-existing ontologies. The goal is to distribute data among stakeholders and establish a decision support system for the energy community. The digital twin implementation integrates IoT technologies, Big Data analysis, and territorial modeling, enabling energy management solutions at both individual (residential) and larger (community) scales.

Introduction

The energy consumption of buildings is a pivotal factor in achieving sustainable development, encompassing economic, environmental, and social dimensions. This theme of sustainability is currently a high priority in global and European policies. In the European Union, buildings account for 40% of energy consumption and 36% of climate-altering emissions (Energy Efficiency in Buildings - European Commission.

In 2019, the European Community launched the European Green Deal, a comprehensive suite of strategic initiatives aimed at combating climate change and global warming. The primary objective of this plan is to achieve climate neutrality by 2050 (Fit for 55 - The EU's plan for a green transition - Consilium.

The European Green Deal highlights the need for a holistic and cross-sectoral approach to address climate challenges, where key sectors such as climate, environment, energy, transportation, industry, and agriculture work in synergy (EU 2019).

These initiatives are pivotal in reducing energy poverty, decreasing carbon emissions, and promoting energy independence(In focus: How can the EU help those touched by energy poverty?).

The emergence of new paradigms and innovative systems, such as Collective Self-Consumption models and Energy Communities, represents a significant shift in energy strategies. These community-focused energy models are transforming the landscape of renewable energy production, distribution, and consumption. Central to these models are the principles of localization and decentralization of energy generation.

Involving citizens, commercial entities, and local businesses, these models facilitate the creation, consumption, and exchange of energy with an emphasis on self-consumption and collaborative effort. Community energy systems and collective self-consumption facilities offer several advantages over traditional energy production models. These include the optimal combination of diverse consumption profiles, immediate utilization of generated energy, and a reduced load on existing grid infrastructures.

This approach not only contributes to environmental sustainability but also fosters a sense of community and collective responsibility towards energy consumption and climate action. Such initiatives, supported by policies like the European Green Deal, are essential steps towards a sustainable, energy-efficient future (Pisello et al. 2023).

Self-consumption of energy can take place at three different levels: individual, collective and community.

The concept of collective self-consumption is defined in the EU Directive 2018/2001(Directive EU - 2018/2001). The directive stipulates that the group of self-consumers (minimum two) who act collectively must be in the same building or condominium.

The text also stipulates that they can generate renewable electrical energy for their own consumption and can store or sell self-produced electrical energy. The main condition is that such activities do not constitute the main commercial or professional activity.

The consumer in the realm of renewable electricity is no longer merely a recipient of energy but has evolved into a 'prosumer.' The term 'prosumer' denotes a user who actively participates in all stages of energy production, as opposed to solely fulfilling the passive role of a consumer. A key advantage of this paradigm shift is the ability for individuals to act collectively, thereby sharing the costs and benefits of such systems, which may include joint maintenance and other pertinent practices.

Legally, participants in these systems share the energy they generate through the existing distribution network.

Each member is equipped with their own meter to measure individual consumption. However, to accurately assess the amount of energy shared for self-consumption purposes, the installation of a secondary metering system is necessary. This system is crucial for monitoring the distribution and sharing of generated energy among the participants.

Despite sharing the overarching goal of enhancing the management of renewable energy generation and usage, there are notable differences between Self-Consumption Units (SCUs) and Renewable Energy Communities (RECs). The primary distinction lies in their composition. An energy community, as defined by the EU Directives 2018/2001(Directive - 2018/2001) and 2019/944(Directive (EU) 2019/944 of the European Parliament and of the Council on common rules for the internal market for electricity and amending Directive 2012/27/EU, is typically comprised of associations of citizens, businesses, local administrations, and small enterprises. These entities collectively decide to produce, exchange, and consume energy derived from local renewable sources (Menegon et al. 2021). This collaborative approach not only fosters a sense of community but also aligns with broader objectives of sustainability and local empowerment in energy production and consumption (Notton et al. 2018).

The Digital Twin (DT) is revolutionising the energy sector by providing an innovative approach to management and monitoring. It enables the management of on-site energy exchanges, optimises the use of renewable resources, and allows users to monitor their own energy consumption (Xiong et al. 2021; Bortolini et al. 2022; Tahmasebinia et al. 2023; Testasecca et al. 2023). The future energy system finds a valuable support in the concept of the digital twin, as developed by Michael Grieves (Grieves and Vickers 2016).

According to Grieves, the Digital Twin (DT) system is based on three main elements: real-world physical products, their virtual counterparts, and the data connections between them. This setup allows the virtual model to mimic the real object's behavior, ensuring changes in the physical product are reflected in the digital one, often through IoT devices and sensors. (Barricelli et al. 2019). Digital twins in the construction sector facilitate the integration of the building's informational and physical models, thereby ensuring iterative optimization of both models. The DT leverages the geometric and parametric properties of Building Information Modeling (BIM) models, as well as streaming environmental data (e.g., temperature, humidity, consumption, etc.) collected from sensors (Brilakis et al. 2019). BIM serves as a common knowledge resource that can be employed as a singular source for data management and collection, facilitating the sharing, preservation, and provision of reliable guidance throughout the building's lifecycle. Data access is enabled through various mechanisms, including proprietary system manual interfaces, Application Programming Interfaces (APIs), and exporting via standard formats such as Industry Foundation Classes (IFC). To date, a unified standard in the IoT and BIM domain has yet to be established, yet numerous open standards are emerging. These are intended to provide a common language across different systems and devices, enabling interoperability and seamless communication among various entities. However, research on the integration between BIM and IoT remains in its nascent stages, where most studies primarily introduce conceptual theoretical propositions (Mengistu and Mahesh 2020; Tai et al. 2021). The importance of digital twins in the construction sector is underscored by the emerging demands for intelligent systems that are capable of representation, analysis, identification, and the enhancement of consumption patterns(Jradi and Bjornskov 2023). Efficient energy management necessitates a reliable data source through the transmission of data from an IoT infrastructure. Employing advanced methods such as machine learning, artificial intelligence, and deep learning, energy community managers can monitor, collect, and analyse data to produce reports, charts, and integrate informational models. Predictive analytics can be utilized to foresee potential issues and undertake preventative measures before they escalate into problems. With these tools, energy community managers make more informed decisions to the benefit of the RECs. Energy data analysis is a crucial aspect of understanding and managing consumption. By interpreting the collected data, RECs members can gain valuable insights into their energy consumption patterns and trends. This knowledge can assist them in making more informed decisions on how to best utilize their resources and reduce costs (Al-Ali et al. 2017; Adu-Kankam and Camarinha-Matos 2023). The digital twin is revolutionising the energy sector by amalgamating the prowess of IoT technology, Big Data analytics, and informational and spatial modelling. This facilitates the deployment of energy management solutions both at a granular level (individual residential units) and at a broader scale (energy communities). This endeavour seeks to delineate a methodological approach that affords RECs members facile access to data and to devise a system that aids them in making well-informed decisions. The methodology employs a variety of tools and techniques, such as statistical analysis and machine learning, to scrutinise data and generate reports.

The principal objective is to proffer an efficacious framework for the cataloguing, storage, and management of multidisciplinary data and information utilising web-based digital systems. This system ought to be scalable, secure, and user-friendly, enabling users to access and meticulously analyse data with alacrity. The chief aim of the methodology lies in the dissemination of reports among the diverse REC members, as well as in the development of a decision-support system.

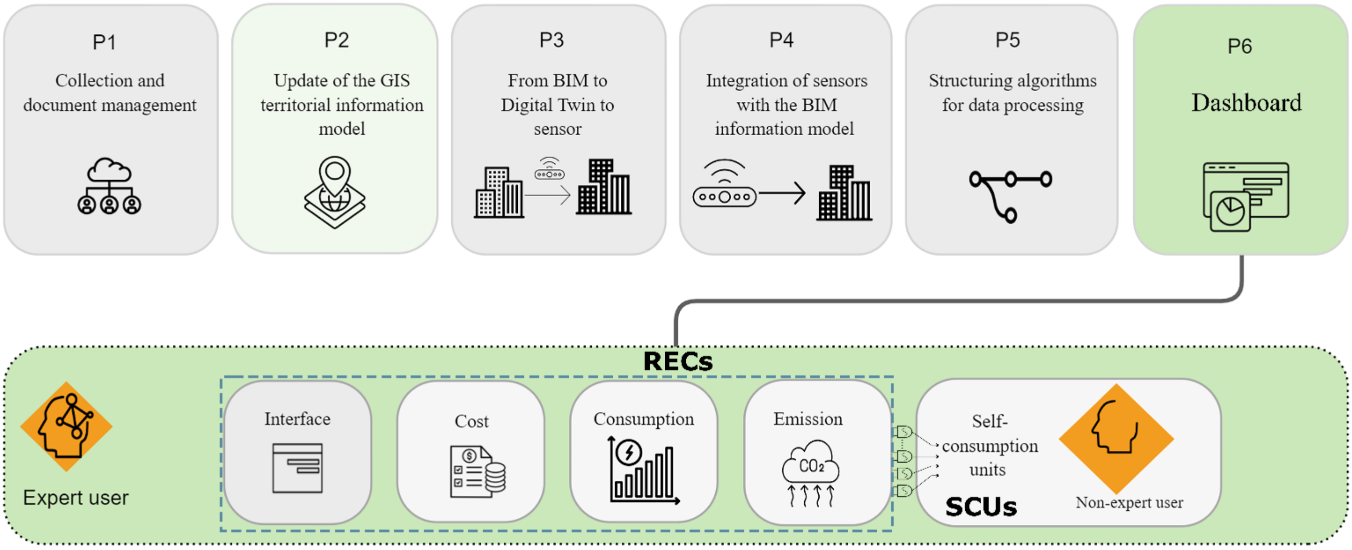

Figure 1 Methodological Framework

Methodology

A comprehensive framework designed to bolster self-consumption units and complex systems like Energy Communities. This research work provides an analysis of current tools, their features, and the best practices for their application to develop an effective management and monitoring infrastructure. The system facilitates the creation of geographical interfaces for community energy operators through the integration of digital twin technologies. Digital Twins (DTs) lack sufficient autonomy to optimise consumption based on information received from Building Information Modelling (BIM) and Internet of Things (IoT) systems, as the unpredictable behaviour of occupants plays a pivotal role. Energy consumption is significantly influenced by user intentions and goals, as well as their expectations in terms of energy savings. With the support system, all stakeholders can better manage the community's economic framework and energy efficiency programmes. REC members have access to the latest updates on the energy system and benefit from reliable recommendations to make informed decisions.

The framework designed to support the management and monitoring processes of the energy community is based on a portal (Web-GIS) containing specific interfaces for sharing information about the energy community and collective self-consumption units. The digital techniques underpinning the methodological framework include Geographic Information Systems (GIS-based), useful for georeferencing different energy communities, primary and secondary substations, followed by architectural entities. The digital techniques underpinning the methodological framework include Geographic Information Systems (GIS-based), useful for georeferencing different energy communities, primary and secondary substations, followed by architectural entities.

i. BIM digital models of buildings structured according to the proprietary guidelines of the energy community. BIM models are implemented on the platform using web-based graphic libraries.

ii. Relational databases structured for the systematisation and querying of data.

iii. Machine Learning algorithms for energy profiling divided into clusters and future predictions of consumption and costs.

iv. Web-based systems for report provision.

The proposed methodology is divided into document collection and management; updating the GIS territorial information model; from BIM to Digital Twin; integration of sensors with the BIM information model; structuring algorithms for data processing and conceptualisation of the dashboard.

P1: Collection and Document Management

This part is dedicated to the cataloguing and administration of documents within the energy community, as well as the pivotal elements that must be incorporated into the process. Entities such as local authorities, citizens, associations, and businesses are required to upload data pertinent to the RECs or collective SCUs. The assemblage and management of documents entail the structuring of a pre-established repository. The subsequent step involves their cataloguing to facilitate ease of search and retrieval. This includes the employment of metadata tags and other forms of categorisation to ensure that data are readily accessible. Once organised and catalogued, the data must be stored in a secure and reliable manner. The most critical phase of the process is data management, which entails ensuring regular updates and protection of the data, and that all

Figure 2 Illustration of a GIS spatial model applied to RECs

participants in the REC have access to the necessary information. The documents must provide clear instructions and information on different aspects of the energy community. Technical reports, safety verifications, regulatory documents, and statutes must all be included in this list. The collection of this information is essential to support the community. To ensure secure and reliable storage, the system must be hosted on the cloud or another reliable storage infrastructure. The collection and management of documents are fundamental tools to facilitate the efficient functioning of the REC.

P2: Update of the GIS Territorial Information Model

The second section is dedicated on sharing a geographical representation of the current state of the energy community. A colour-coding system identifies the various communities with individual self-consumption units. Regarding buildings, there are three distinct types of input data essential for defining the territorial information model. The first type is derived from national statistical institutes' censuses across Europe which furnish essential details regarding the age of buildings. The second type of data emanates from regional topographical databases, which include, among other details, information on the buildings' intended use. The final categorisation originates from Building Information Modeling (BIM) systems, incorporating both geometric data and consumption metrics.

The confluence of these databases facilitates the determination of specific characteristics for each building, such as its age class, surface-to-volume (S/V) ratio, number of storeys, and occupant count. Utilizing the GIS system, in conjunction with previously prepared BIM models, smart meters' analyses are conducted to glean precise consumption data. Following the delineation and consumption allocation to building clusters, the data are aggregated into summary tables. Grasping the behavioural dynamics of a community of buildings throughout the year is paramount, as it harbours significant practical ramifications for the management of RECs.

P3: From BIM to Digital Twin

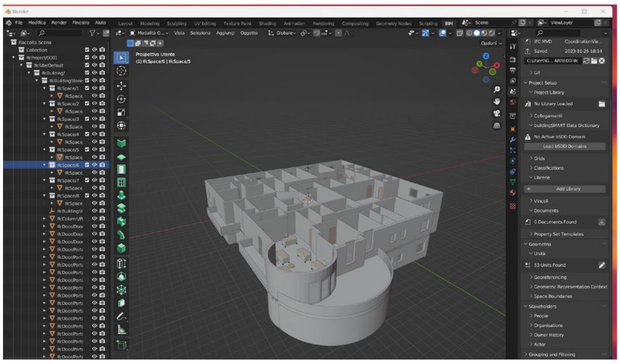

Figure 3 Building Information Model (Simplified Representation), Blender with BIM Add-on

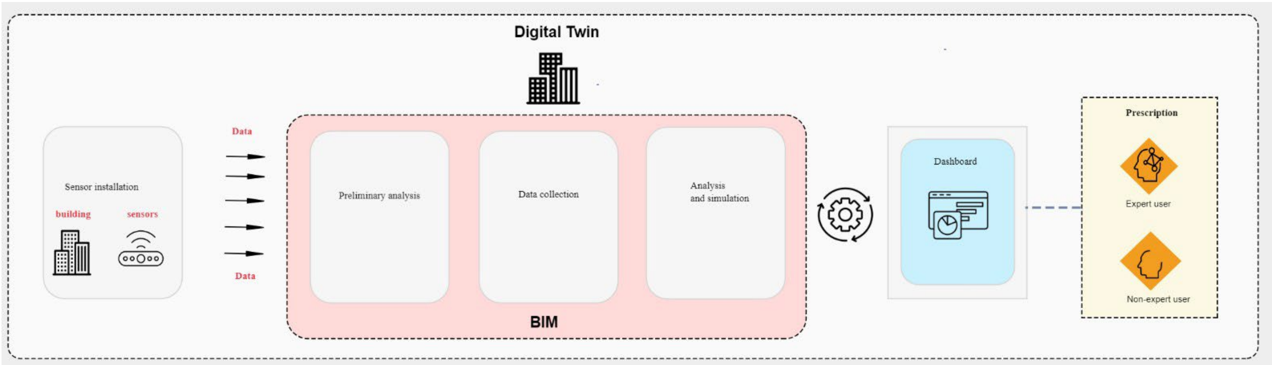

Figure 4 Flowcharts: from BIM to Digital Twin

A digital twin can be conceived in several stages, yet it is most efficacious when established in the initial design phase of self-consumption units; hence, the data amassed can serve as a foundation for managing subsequent stages.

Building Information Modelling (BIM) is the most apt approach for creating the building's digital twin, as it is integrated with parameters functional to the monitoring phase. Furthermore, it is employed as a source for the collection and management of data which is conveyed to the GIS-based territorial system. Although BIM encompasses information about the building and space, it cannot solely provide comprehensive insights into the building's behaviour upon which to base decisions for the community or individual users. To this end, this endeavour integrates the model with information gathered in the initial phase (P1), such as the building's typology, residential units, and the occupancy level of the users. To ensure the correct implementation of the digital twin, it is crucial to associate all necessary documents for the selection and installation of the sensor network with the BIM. Supported by the informative model, we are capable of precisely determining the optimal placement for each individual sensor, thereby enabling the REC to maximise the network's performance and minimise the costs associated with installation.

P4: Integration of Sensors with the BIM

The objective of this phase is to identify the most suitable type of sensors for the construction of a monitoring system, taking into account the requirements and spatial properties of the structures identified in the previous analysis (P3). As part of this step, the techniques for sampling and transmitting data from the control devices are outlined and implemented. The application of smart meters for monitoring energy consumption, along with sensors, facilitates the analysis of usage habits within individual residential units. Utilising data from both external and internal temperatures can enhance the prediction of energy consumption. It is essential to determine the type of monitoring device that best suits the specific needs of the building. This task involves a thorough analysis of performance, application limits, and costs of available technologies. Given that the expenditure required for hardware is one of the most significant concerns for households, this study leans towards a non-intrusive monitoring system with economical sensors that are easily programmable to minimise the cost of the entire system. BIM can provide significant assistance in this phase to define various sensor configurations and compare them as an additional source of information in the building.

In addition to the technical and economic considerations, the security of the data collected and transmitted by these sensors warrants careful attention. The integrity and confidentiality of data within the monitoring system are paramount, necessitating the implementation of robust encryption protocols to safeguard data in transit and at rest. User authentication and access controls are crucial to ensure that only authorized individuals can access sensitive information, thereby preserving the privacy of the residential units involved. The proposed system will also explore the adoption of blockchain technology to provide an immutable ledger for data transactions, enhancing trust and transparency within the community. By incorporating these security measures, the monitoring system not only optimizes energy consumption and operational efficiency but also ensures the protection of sensitive data, aligning with global standards for data privacy and security.

P5: Data Processing Algorithms

In the context of refining the BIM information model, it is essential to elaborate on the development of sophisticated algorithms tailored for the efficient management of data captured by monitoring sensors. The integration of sensor-generated data with BIM-centric applications is achieved through Python scripting. These scripts are not merely facilitative but are at the core of the data processing mechanism, enabling a dynamic and seamless exchange of data between the sensor array and the BIM ecosystem. Such integration is pivotal for real-time data analysis and automated responses within the BIM framework.

Further enhancing the functionality of these scripts, machine learning algorithms are deployed to scrutinize patterns in energy consumption meticulously. These algorithms are adept at sifting through vast datasets to identify anomalies and inefficiencies that may not be immediately apparent. By learning from historical data, they can predict future trends, enabling preemptive actions to optimize energy use and reduce waste. This is particularly beneficial in managing complex systems such as HVAC and in the predictive maintenance of various devices and machinery, where early detection of potential issues can prevent costly downtimes and repairs.

The strategic use of machine learning in this domain not only enhances operational efficiency but also contributes significantly to energy conservation efforts. By analyzing consumption patterns and identifying areas of excessive use, these algorithms can provide actionable insights for energy savings. This leads to the development of targeted recommendations that are both pragmatic and feasible, ensuring sustainable energy utilization across different applications. Moreover, the predictive capabilities of machine learning algorithms extend to forecasting maintenance needs, thereby alerting facility managers and consumers well before potential system failures occur, ensuring reliability and continuous operation.

P6: Dashboard Conceptualization

The dashboard is conceptualized as an interactive tool for the visualization and interpretation of data originating from a centralized storage system. It employs an analytics engine to convert raw data into intelligible reports, charts, and diagrams. The dashboard is customized to cater to diverse user groups, each with varying levels of expertise and access rights.

For novice users, the dashboard is made accessible through a cross-platform mobile application, enabling them to view summary charts that provide an overview of pertinent data related to their self-consumption units, along with a straightforward depiction of REC. Conversely, community managers are provided with a more comprehensive desktop interface for conducting detailed analyses, thereby facilitating informed decision-making processes.

The dashboard architecture is predicated on user privilege levels, thereby dictating the granularity of the presented data. Expert users are afforded extensive visibility, ranging from a holistic view of the energy community to detailed information on self-consumptions units. Novice users, on the other hand, are presented with data relevant to their specific dwelling units, complemented by summary reports that encapsulate key information about their own energy community.

The dashboard is segmented into four main sections, each designed to highlight different aspects of the energy community's data:

General Data: This section employs geographical visualization to outline the energy community's layout, identifying communities and associated substations through a color-coding scheme. An integrated alert mechanism proactively notifies expert users of necessary actions within the RECs framework. Additionally, this section provides direct access to essential REC documentation, such as community statutes and incentive management guidelines.

Costs and Consumption: Acknowledging the significance of financial and consumption metrics in energy resource management, this section provides insights into energy costs, consumption patterns, and future projections. It includes a comprehensive report detailing the energy costs of community-level and individual self-consumption units, breakdowns by energy source, incentive allocations, comparative analyses with similar communities, and future cost and consumption forecasts. Graphical alerts are utilized to signal anomalies, encouraging users to modify their consumption behaviors.

Emissions: This segment enables community members to monitor and assess the REC's contribution to CO2 emission reduction, providing a tangible measure of the community's sustainability efforts.

Self-Consumption Units (Novice User): Tailored for novice users, this section offers an interface that allows users to access summary information from the previous sections specific to them own self-consumption unit, thereby facilitating an intuitive and streamlined user experience.

The dashboard is designed not merely to present data but also to enhance user engagement and awareness of specific aspects of the energy community, thereby enabling users to make informed decisions based on the presented data.

Discussion

The deployment of this dashboard heralds a substantial advancement in the domain of renewable energy management, pertinent to both SCUs and RECs. Its primary objective is to streamline the engagement with sustainable energy practices, rendering them more accessible and intuitive to the end-users.

Within the confines of SCUs, which serve as the nucleus of individual energy production and consumption dynamics, the dashboard emerges as an instrumental tool. It leverages real-time monitoring capabilities to discern patterns of peak energy production, often coinciding with troughs in energy consumption. This synchronicity allows the dashboard to advocate for the scheduling of energy-intensive tasks during periods of abundant renewable energy generation, thereby optimizing the utility of renewable resources.

Expanding its utility to the broader ambit of RECs, the dashboard plays a pivotal role in the nuanced orchestration of energy flows among a consortium of interconnected entities. It aids in the strategic allocation of surplus energy, ensuring its efficacious distribution within the community. This strategic approach to energy management engenders a harmonious balance within the REC, mitigating the challenges posed by the inherent variability of renewable energy sources.

Furthermore, the dashboard transcends its operational utility by incorporating a predictive maintenance feature, crucial for the proactive upkeep of renewable energy systems. By continuously monitoring the health and efficiency of these systems, it preemptively identifies potential issues, thereby safeguarding the continuous optimal performance of energy assets.

In its essence, the dashboard also serves as a decision-support system, facilitating strategic planning for the expansion or augmentation of renewable energy infrastructures within RECs. By amalgamating diverse data streams, including historical energy consumption patterns, current trends, and predictive analytics, it furnishes a holistic view of the energy landscape. This empowers stakeholders with the necessary insights for informed decision-making regarding future investments in renewable energy technologies, thus reinforcing the community's trajectory towards sustainable energy practices.

Conclusions

This work outlines a comprehensive methodological framework designed to bolster the efficacy and operational efficiency of Energy Communities (RECs).

The primary objective of this initiative is to devise an advanced, user-friendly dashboard that offers real-time insights into the performance metrics of RECs, alongside granular data on each individual self-consumption unit. This is particularly focused on providing detailed information regarding costs and consumption patterns. The significance of this contribution lies in its ability to facilitate industry experts in their endeavors to effectively manage and monitor RECs by leveraging sophisticated digital models, cutting-edge geographic information systems, and robust web-based relational databases.

Addressing the pervasive issue of data fragmentation and cognitive heterogeneity in the building sector is paramount. This sector is characterized by the disparate structuring of data across numerous repositories, which inevitably leads to critical information gaps. This fragmentation hinders the seamless management and interpretation of data within energy communities or collective self-consumption systems. Therefore, it is of utmost importance to equip energy community managers with a streamlined, intuitive platform that presents essential information in a clear, accessible manner. This approach is vital for bridging the information divide and enhancing the decision-making process.

In parallel, the promotion of a smart energy system is instrumental in motivating individuals to alter their energy consumption behaviours towards more sustainable and environmentally friendly practices. This necessitates a robust support framework that not only facilitates the digital transformation of services and the automation of processes but also emphasizes the empowerment of REC members. The analysis conducted by the International Energy Agency underscores the critical role of citizen involvement in the successful adoption and optimal utilization of future technologies within the energy sector.

Looking forward, the potential for engaging members and fostering a sense of credibility and trust within local communities cannot be overstated. Hence, future research endeavors will be directed towards exploring the realms of training, knowledge dissemination, and strategic communication activities. These areas are identified as pivotal for the sustained growth and impactful operation of RECs. Such initiatives will aim to enhance the collective understanding of energy management practices, promote widespread adoption of sustainable energy solutions, and ultimately contribute to the overarching goals of energy efficiency and environmental stewardship.

OPTIMIZING ROAD INFRASTRUCTURE DESIGN USING I-BIM TECHNOLOGY

Panagiotis Tsikas, Rebeca Giavi, Athanasios Chassiakos
Department of Civil Engineering, University of Patras, Patras, Greece

Abstract

Infrastructure Building Information Modeling (I-BIM) has emerged as an important supporting technology for managing infrastructure project design, construction, and operation. This paper presents the development of an I-BIM model that can holistically capture the components and their integration characteristics of a road project. Extending previous works, the development deems to provide detailed road design analysis including drainage, signage, and lighting, traffic lanes of variable width, inclined pavement layers, vegetation and plantation, etc. In addition, the difficulties in developing “irregular” components and aligning them with each other and with the longitudinal land terrain are examined. The development applies to a real-world road design to explore the applicability potential.

Introduction

Transport infrastructure projects, being large scale engineering ones, require significant capital investments for their construction and maintenance, in return to multiple benefits for the users and the society out of their operation (Timilsina et al. 2020). In fact, they are quite important projects playing a key role in the social and economic development of regions and countries, often echoing the economic and technological development of them (Cigu et al. 2019).

The continuous improvement and application of new methods to improve the design and operation of such projects is always a goal (Costin et al. 2018). Considering the potential and positive effect of applying BIM technologies in construction (Wong and Fan 2013), the application and use of such tools in infrastructure project management could provide an effective method to increase efficiency during the project life cycle.

In large scale infrastructure projects, cost overruns, completion time overflow, wastefulness, and performance loss constitute conventionality rather than exception (Love et al. 2014). Engineering challenges - arising mainly from the specificities of such projects - exhibit a wide variety in terms of structural, geometrical, and mechanical characteristics. On the other hand, such projects are spawned by various multidisciplinary groups (architects, engineers, contractors, operators, etc.) having different (and often conflicting) priorities and objectives at every project phase. As a result, there is a large volume of information, generated from start to finish, subject to managing deficiencies and performance degradation.

Liu et al. (2017), after studying the most important risks in engineering projects through a questionnaire shared with 500 construction companies, noted that project performance - in terms of time, cost, quality, and safety - is significantly affected by the design team capability, the information accuracy, and the design associated delays. Undoubtedly, all the above factors contribute to problems and risks that infrastructure projects face nowadays and in the past. The root cause, according to Flyvbjerg (2013), is the fact that project planners tend to systematically underestimate or even ignore project complexity risks during the project development phase and decision making. Thus, many problems are associated with project design (or communication about the design), while modifications made alongside the way are related to deficiencies or omissions by the design.

As a result, both the productivity and the efficiency of the projects remain modest (Agenda, I. 2016). In this context, the traditional ways for managing infrastructure projects cannot meet the challenges of today, where construction is becoming more and more complex and demanding, and these projects require adequate planning and prudent resource management. Teizer (2015) stresses that key issues in the direction of improving infrastructure project management include schedule obedience, material procurement, supply chain-related actions, project status control, safety and quality monitoring. Furthermore, as Chi et al. (2012) state, during the evolution of a project, interim and ad hoc works arise. Because of this, the design of such temporary works does not always receive the attention and control levels that are typically required. Therefore, these elements should be integrated within the design, construction performance and safety parameters.

The introduction and use of BIM technology in the construction industry has assisted in automating traditional processes, manifesting positive effects in quality and productivity (Ullah et al. 2019). In addition, the adoption of BIM has significantly contributed to the digital transformation of the general industry, moving from the traditional way of designing and planning typical construction projects (e.g., buildings) towards a digital ecosystem that includes 3D visualization and real-time communication. Instead, in large infrastructure projects, the application and adoption level of BIM technologies is lacking behind, resulting in lower productivity and efficiency outcomes.

In recent years, there have been steps forward in the application and use of BIM in the infrastructure sector, as the benefits of 3D modelling and the use of smart objects are increasingly recognized (Tang et al. 2020; Cantisani et al. 2022). A 3D/BIM model is not limited to the geometric and design features visualized in the simulation (Gould 2010) but it is like a digital simulation model of the actual structure, whose properties and features are fully configurable. Thus, BIM technology is a reliable design tool that provides access to a comprehensive set of knowledge about the form, materials, environment, technical characteristics, costs, etc. of the project.

Despite the numerous benefits of I-BIM and the development of implementation strategies, the application of this technology remains limited, and the overall effectiveness of BIM in real projects has not been fully studied. Therefore, there is a need to explore the practical application of Infrastructure BIM (I-BIM) technology in the planning and design of projects. In this paper, the development and description of such a system for road projects is presented and discussed.

Infrastructure BIM

The development of road infrastructure projects involves two phases, the design and the construction ones. There are several sub-stages, in which plans and documents are produced, relating, among others, the technical specifications of the design, the cost and the duration of the construction.

In the traditional approach, communication among stakeholders has been largely fragmented and based on the exchange of 2D drawings and documents. As a result, coordination is particularly difficult, as much information (data) is lost or miscommunicated in the transition from stage to stage, often leading to the need for re-creation. Further, in large-scale projects, there are always large volumes of data and, likewise, it is difficult to communicate and present them correctly. Consequently, data omissions or miscommunication lead to inaccurate information sharing among participants and project phases. As such, when errors are detected through the several steps, the project has already progressed making any needed intervention difficult, costly, time consuming, and often of inadequate effectiveness.

In contrast, in infrastructure BIM (I-BIM) management, the information flow is coordinated in real time so that the work execution can be carried out by all involved parties (of different branches) effectively, as the digital simulation of the construction is up to date to the needed modifications and project progress monitoring. Thus, decision making for changes can be carried out in the early stage where the cost of changes is low and their effectiveness is high. Hence, more efficient collaboration is achieved by all groups involved in all phases throughout the project life cycle, eventually leading to an effective design and construction decision making.

Methodology

I-BIM provides a comprehensive 3D visual database and modeling of the project under development, integrating a range of data, including 3D terrain models and road design elements, such as road geometric design, cross-sections, measurements, electromechanicals, hydraulics, and more. This allows for the effective design of road systems and the optimization of project outcome. By integrating more data into the existing 3D model, i.e., work scheduling and construction cost, project managers can validate road project conformance to standards before construction commencement, leading to enhanced project efficiency and effectiveness. Therefore, the use of I-BIM in the initial design phase of large and complex horizontal geometry projects, can significantly contribute to different scenarios evaluation by providing visual, qualitative, and quantitative information that helps in the direction of selecting the best scenario that minimizes the time and cost and improves the quality of the work.

The design methodology of the road project through I-BIM includes the following steps, in accordance with the conventional way of doing things:

- Capture the terrain surface along the road alignment.
- Model the road and its individual elements (road deck, positions of sidewalks, roundabouts, islands, crossings, overpass bridge).
- Visualize the core road elements and layers in a 3D representation.
- Model and present secondary road elements that are necessary for road operation (signs, lighting fixtures, planting objects, etc).

Unlike traditional techniques and programs, all elements and characteristics of the project are present in a single 3D/I-BIM model. This enables the visualization of the road design in a realistic environment, which is helpful in identifying any potential conflicts that may arise. Most importantly, alternative design scenarios can be easily simulated and evaluated to realize the best layout solutions. Further, the I-BIM technology facilitates collaboration among the design team members by allowing them to access and modify the single digital model in real-time.

Interoperability and data standardization, using openBIM technology and Industry Foundation Classes (IFC), are vital for efficient information exchange among different stakeholders in the construction process. In this direction, the IFC 4.3 format is a significant step toward automating and optimizing facility management within the project lifecycle. In the road design study, interoperability helps transferring topographical mapping from AutoCAD Civil 3D to Revit for further processing and enhancing decision-making and stakeholder communication in project design.

Case study

As part of the development, this work presents as a case study the employment of the I-BIM technology to the design of the new ring road in Nemea (Greece). The 3D modeling of the road and its elements (road surface, sidewalk, roundabouts, electric lighting, technical works, etc.) has been realized using the AutoDesk REVIT software. Such kind of software have been developed with an initial focus on building design and construction, at least in construction industry applications. It appears, however, that they can effectively be used for other types and large-scale projects.

The terrain design of the area has been based on topographic CAD diagrams, which are first adjusted to their actual dimensions during modeling in REVIT. The adoption of BIM in this project has largely focused on design activities. The existing road passes through the urban area of the city of Nemea, as shown in Figure 1. As a result, traffic congestion is observed within the city that results in increased travel times and accident risk. The latter is more evident at an intersection where the new road is going to commence, in which case the intersection angles of the current geometry of the converging roads provide very poor visibility conditions (Figure 2). The bypass follows a new alignment, totaling 1.4 km, starting at location (1) and ending at location (2), as shown in Figures 2 and 3. The new road design includes two roundabouts at its ends to ensure high safety conditions and smooth traffic flow.

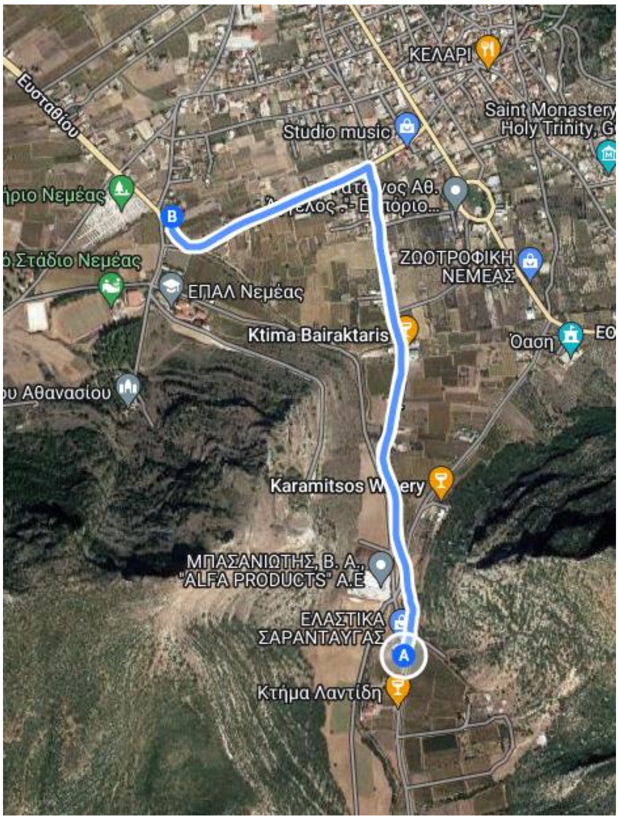

Figure 1: Existing road through the urban area

To select the optimal layout, several design alternatives have been developed and evaluated along the land zone around the potential layouts, with special emphasis to the roundabouts that link the ring road with the existing road segments. The proposed layout is shown in Figure 4.

The new road design features a nominal speed V_e = 60 km/hr, horizontal radius of R $\geq$ 140 m, and maximum longitudinal gradient 3.80%. The road consists of two lanes (one per direction) with an effective road width of 7.00 m plus 2.00 m of sidewalk. Further, at the roundabout access sections, appropriate widening of the roadway is designed. Along the entire length of the road, guard rails of 0.60 m in height have been laterally designed in both directions.

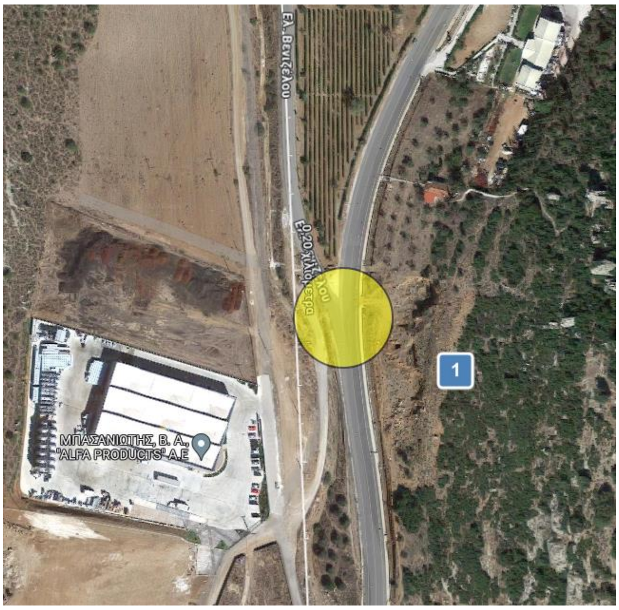

Figure 2: A high accident risk segment of the existing road design (point 1, same as point A in Figure 1)

The full project model, encompassing all the information, is depicted in Figure 5 and allows efficient project analysis and management. As stated before, the utilization of such a model facilitates the effective management of changes at any project component (e.g., drainage system) and the direct communication of such changes at all management levels and stakeholders.

The cross-section of the carriageway comprises multiple layers that include (from the lowermost to the uppermost level): two layers of sub-base of 10 cm thickness each, two layers of base of 10 cm likewise, asphalt pre-coating, asphalt base layer of 5 cm thickness, asphalt adhesive coating, asphalt traffic layer of 5 cm thickness, asphalt adhesive coating, and asphalt anti-slip layer of 4 cm thickness. All layers have been simulated in the 3D/BIM model (Figure 6).

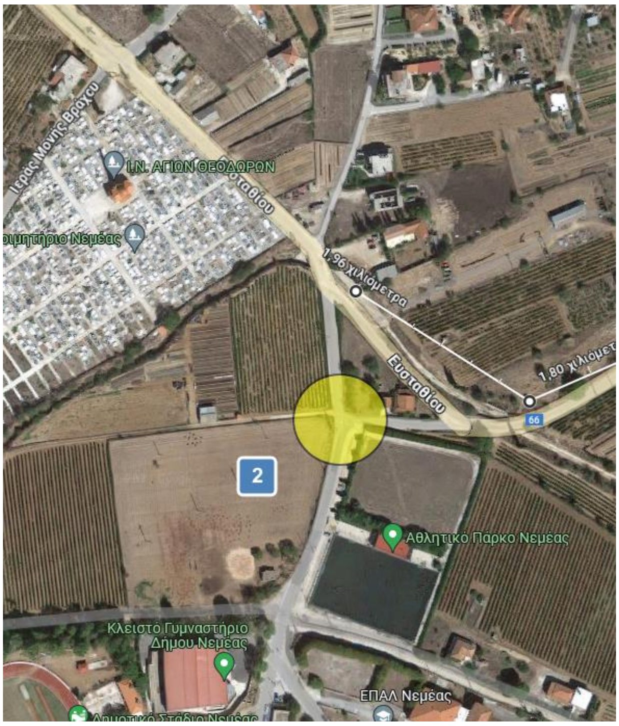

Figure 3: Endpoint of the ring road (point 2, same as point B in Figure 1)

Figure 4: Ring road alignment design

The design of the roundabouts has been carried out in accordance with the "Geometric Design of Highways and Streets" (Hancock et al. 2013) and "Roundabouts: An Informational Guide" (Robinson et al. 2000). The proposed roundabout layouts allow for convenient and safe pedestrian and vehicle access on the ring road. Figures 7 and 8 display the configuration of roundabouts 1 and 2 respectively. To reinstate the connection with local roads, two level junctions (N1 and N2, in Figure 5) have been designed. The junctions, as they have been designed and simulated in the 3D/BIM model, are illustrated in Figures 9 and 10 respectively.

Horizontal and vertical signage has been designed and installed along the entire length of the road to guide the drivers and effectively regulate the traffic. An indicative case is shown in Figure 11 for roundabout 2.

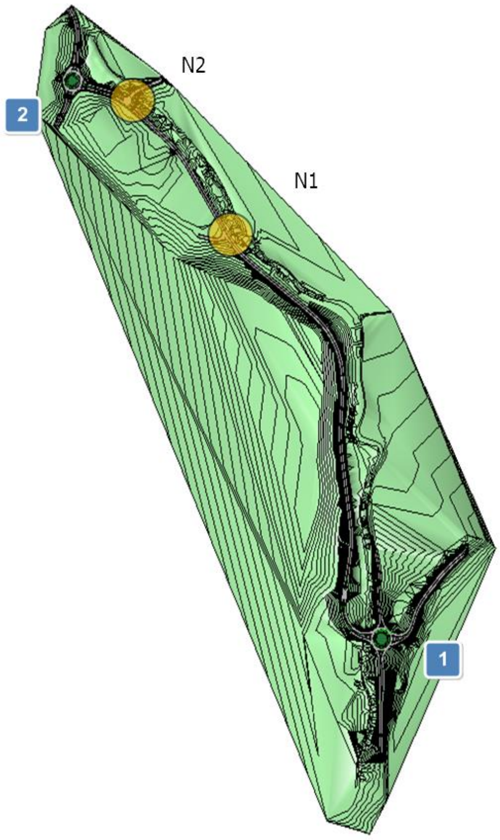

Figure 5: 3D/BIM model of the ring road

Figure 7: Visualization of roundabout 1

Figure 8: Visualization of roundabout 2

Figure 9: Visualization of road junction N1

Figure 10: Visualization of road junction N2

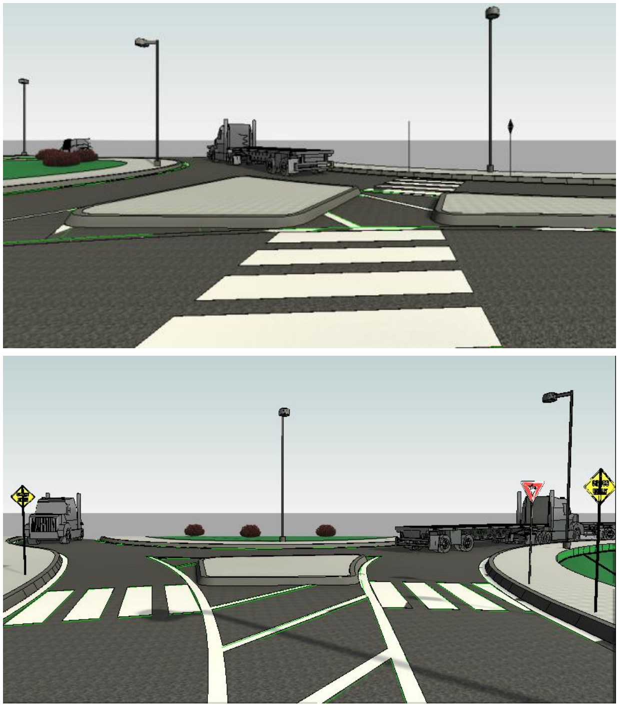

Figure 11: Horizontal marking and vertical signs at roundabout 2

Further, road lighting design has been performed through the 3D/BIM model, which pointed that a total of 51 luminaires of 150-Watt power and 16,100 lumen luminous flux are required to be installed. Figure 12 indicatively presents the electric lighting scheme at the roundabout 2 zone.

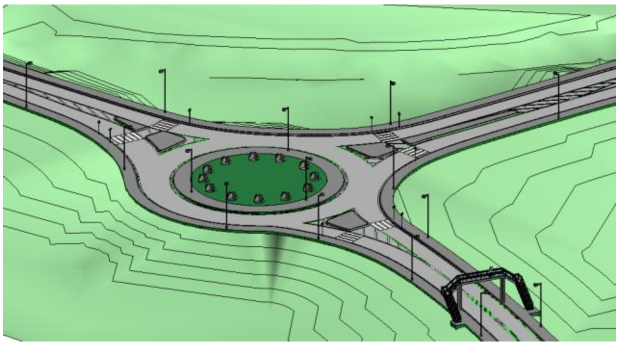

Figure 12: Electric lighting system in roundabout 2.

Analyses and cost estimation of the project have been carried out through the I-BIM model. The estimates can be either for single elements or groups of elements of the project. As an example, the costs for signs and for railings are presented in Tables 1 and 2 respectively, as reported by the software. Similar tables have been developed for all project components. Considering typical unit cost values for Greece, a total cost of 2.32 million € has been estimated for the whole project construction.

Discussion and Conclusions

This study describes the potential and advantages of BIM technology in the design of large infrastructure projects, in this case the ring road of Nemea city in Greece. Opposite to the common belief that BIM technology is mainly applicable to buildings, it can be proven to be equally applicable to infrastructure projects. In this work, I-BIM simulation is particularly effective as it combines parametric 3D simulation and high-level information codification to create a virtual digital model of the project, the 3D/BIM multi-level model, the use of which highly improves the processing, design, planning and management of the project construction and operation.

The importance of using BIM technologies is undoubtedly related to participant coordination and information sharing, the identification and resolving of conflicts at early stage or the evaluation of alternative design solutions. These aspects of BIM tools are rather well known and not widely discussed in this paper. The main goal of this work is to dig into the details of a road infrastructure project and explore whether BIM software can represent them in an integrated way for the design, construction, operation, maintenance, and management to increase interoperability. In addition, the difficulties and barriers in developing the I-BIM model of a project with "irregular" components and in aligning the different elements with each other and with the longitudinal land terrain are explored.

The work outcomes indicate that the project design through Revit (or any other BIM software) is feasible to a high detail, increasing interoperability and allowing all designers to have access to updated project plans at any time and to work collaboratively, thus significantly reducing effort and errors in design. In addition, the 4D and 5D representation of the project, through the time and cost showcase, provides aforehand information on the expected project progress and cost evolution and enhances decision-making and stakeholder communication during construction, leading to higher quality at lower cost.

Grand total: 28			142831.53€

Unlike typical building design, in which components are of "regular" (e.g., rectangular) shapes, infrastructure project design presents extensive challenges in terms of irregular component shapes, material and manufacturer specificities, and component alignment needs within an integrated design. For example, pavement layers need to be aligned among them and along the road sections (e.g., joins at main road and entrance/exit sections or road approaches and roundabouts). Conflict resolution needs also to be addressed in reference to the road design adjustment to landscape, the incorporation of drainage system, the pavement cross-section design at curved parts of the road, based on large-truck trajectory analysis, etc. The BIM-software database often needs to be enhanced with specific road design elements and potential vendor information, e.g., horizontal and vertical signage, lighting, vegetation and plantation, etc.

In the present work, the design dives into greater detail, in comparison to previous works, indicating the feasibility potential of such a design. However, some limitations should be expected in practical applications. A main difficulty refers to the exact fitting of the road to the landscape, which is mainly due to the inaccuracies or approximations in the digital representation of this landscape. Another challenge is related to the effective placement of overlapping layers of components that are curved and inclined in the longitudinal and transverse directions (e.g., pavement layers). This can be done by considering smaller sections of uniform shape, which are then aligned at their joins and integrated to the full model.

The I-BIM technology can be successfully used in the design and management of large-scale infrastructure projects. In road projects, in particular, the design can improve traffic flow and safety as well as contribute to drainage, signage, lighting, and aesthetic upgrading. The use of BIM technology in large infrastructure projects reduces the effort required during design and construction, while offering effective tools to manage cost and completion time, to reduce waste, and to improve construction quality performance.

Abstract

The Architecture, Engineering, and Construction industry is crucial in promoting circular economy principles to mitigate resource scarcity and negative environmental impacts. Taking the lead in the global extraction of raw materials and making significant waste contributions, the sector incorporates circular economy assessments into building design decisions. This paper introduces a concept using visual programming language for End-of-Life algorithms linked to Building Information Modelling Data. The goal is to create a decision-support tool for the early design stage using common architectural software coupled to visual programming. The results display a computational solution for implementing relevant parameters through utilised software.

Keywords: Circular economy, digital twins, generative design, virtual reality, digital ecosystem, end of life, material building passports, EU taxonomy

Introduction

The growing interest in the circular economy (CE) represents a paradigm shift from the prevailing linear economy, driven not only by the need for assessment for several certifications and EU regulations but also because of its significant advantages compared to the traditional linear model (United Nations Environment Programme, 2022). These benefits extend to environmental, social, and economic concerns, addressing crucial challenges such as resource scarcity and environmental degradation (Kovacic et al., 2020a; Ellen MacArthur Foundation, 2024; Gorgolewski, 2018; Korhonen et al., 2018; Cramer, 2022). Defining the basic concepts of circular economy and sustainability is essential to provide a framework for this research. The Brundtland Report (1987) offers a widely recognised definition of sustainable development as ”development that meets the needs of the present without compromising the ability of future generations to meet their own needs.” (Brundtland, 1987, p.37). Barbier (1987) was among the first to describe sustainability's three pillars: economic, environmental and social, with this paper concentrating on the environmental aspect (Barbier, 1987). Cramer (2022) introduces the 10 R's, which ranks circularity actions by their impact, placing reuse higher than recycling due to its more significant contribution to circularity (Cramer, 2022). Moreover, Geissdoerfer et al. (2017) define Circular Economy as ”a regenerative system in which resource input and waste, emission, and energy leakage are minimised by slowing, closing, and narrowing material and energy loops. This can be achieved through long-lasting design, maintenance, repair, reuse, remanufacturing, refurbishing, and recycling.” (Geissdoerfer et al., 2017, p.759), positioning it as essential for sustainability.

A transition to a circular system is particularly crucial in the construction industry, contributing to around 37% of global energy consumption and process-related CO2 emissions (United Nations Environment Programme, 2022). Furthermore, this industry's significant role in resource depletion, being the largest contributor to global raw material extraction (Almeida et al., 2016), highlights the need to transition to circular systems. However, this transition challenges existing design processes and policy frameworks, making revisiting and altering current approaches necessary (Korhonen et al., 2018). Therefore, there is a need for a framework to better include circular economy principles, such as reuse or reduce and especially guide cooperation between designers, fabricators and clients in the construction industry (Svilans et al., 2019; Çetin, 2023; Geissdoerfer et al., 2017; Çetin et al., 2021).

Digital tools are seen as critical enablers for efficient data sharing, monitoring, optimisation and enhanced communication between stakeholders throughout the design and construction process (Antikainen et al., 2018; Antova and Tanev, 2020; De Wolf et al., 2020; Martínez Rocamora et al., 2021; Çetin, 2023). Moreover, initiatives like Europe's Digital Decade (European Commission, 2021) and the 2020 EU CE Action Plan highlight the importance of digital tools in promoting sustainability and supporting the circular economy (European Commission, 2021; Çetin, 2023).

As a result, finding computational solutions to embrace a circular economy is among the most recent topics in the Architecture, Engineering and Construction (AEC) industry, as it can tackle today's pressing environmental problems (De Wolf et al., 2020; Kovacic et al., 2020a; Cramer, 2022). Building Information Modelling (BIM) and Material Passports, for example, promise to address sustainability barriers and facilitate the automatic inclusion of reliable datasets (Honic et al., 2019; Çetin, 2023; Martínez Rocamora et al., 2021; Santos et al., 2019). However, there are challenges in integrating these tools, particularly when considering one of the most commonly used methods, Life Cycle Assessment (LCA) (Santos et al., 2019). The reliability of LCA results is affected by uncertainties coming from assumptions, such as energy consumption and product lifespan. Additionally, challenges in integrating specific, local information from manufacturers and the lack of detailed data on material composition in the early design stages further affect the accuracy of LCA outcomes (Martínez Rocamora et al., 2021; Santos et al., 2019; Honic et al., 2019). This highlights the need for more flexible and comprehensive tools within the BIM environment to simplify the integration of environmental analysis in the design process (Martínez Rocamora et al., 2021; Çetin, 2023). Research into BIM-based LCA tools shows that most require a combination of BIM and other software to measure environmental impacts effectively. This process, while beneficial, often requires manual input and thus is time-consuming, contrary to the goal of automating these assessments (Martínez Rocamora et al., 2021; Honic et al., 2019). The need for a multidisciplinary approach comes with its hurdles, as the link between digital tools and circular economy principles requires skills spanning environmental science, architecture, engineering, and programming - raising another limitation: the interoperability issue between different software (Santos et al., 2019). Nevertheless, this collaborative effort is vital for developing tools that are both functional and beneficial (Martínez Rocamora et al., 2021; Ilhan and Yaman, 2016). Despite the identified potential of digital tools to integrate circular economy principles in the AEC industry, there remains a significant gap in creating user-friendly, integrated solutions that effectively bridge the gap between theoretical concepts and their practical application. This highlights the ongoing academic and practical need for research to develop accessible tools that enable sustainable construction practices within the circular economy framework(Ilhan and Yaman, 2016; Çetin, 2023; Martínez Rocamora et al., 2021).

The ongoing research presented in this paper addresses these challenges by aiming to optimise architectural designs in terms of circularity and sustainability in the early design stage, as it promises fundamental advantages, representing a vital phase where materials can enter (or re-enter) a new life cycle, and design concepts are still in their initial adjustable stage, thus more flexible to adapt (Gorgolewski, 2018; Honic et al., 2019; Çetin, 2023; Çetin et al., 2021). This paper emphasises the need to flexibly document, validate and benchmark environmental impacts to ensure current activities support a sustainable future and bridge the gap between abstract principles and practical implications (Çetin, 2023; Geissdoerfer et al., 2017). Therefore, this paper considers key indicators, including the building's overall mass, Global Warming Potential (GWP-total), Acidification Potential (AP), and Primary Energy Non-Renewable, Total (PENRT). These indicators were chosen because they are used in the Austrian klimaaktiv OI3 Eco Index calculation to assess the environmental impact of materials (IBO – Österreichisches Institut für Bauen und Ökologie, 2023), and are also relevant for compliance with the EU Taxonomy classification system (European Commission, 2024).

The concept of this research merges Algorithm Aided Design (AAD), Building Information Modeling (BIM) (Pibal et al., 2022), and Virtual Reality (VR). It supports sustainable architectural planning by automating variant generation, conducting circularity assessments, and using a VR platform interface to facilitate decision-making in the early design stage, aligning with Circular Economy (CE) principles and objectives. The framework of the project is based on:

1. a BIM-based architectural model (in software ArchiCAD)
2. an End-of-Life (EoL) design algorithm to conduct the variant study generating an assessable geometric twin, an identical digital illustration of the variant in the VR platform
3. an EoL- assessment algorithm for attributing and evaluating different building variants
4. VR platform with included Virtual Agent for planning support
5. An enriched spreadsheet-based object catalogue containing relevant data from material databases such as the Austrian database "baubook" (baubook, 2024), essential for conducting defined assessments

This research builds on the previous publication, Wohnen 4.0 (Pibal et al., 2023), Digital Ecosystem to enable Circular Buildings – The Circular Twin Framework Proposal (Schützenhofer et al., 2024) and Digital Platform for Affordable Housing - a Framework Proposal (Kovacic et al., 2020b). The overall context established is visualised in Figure 1, which provides an overview of the proposed framework. This paper focuses on Module 2 and Module 3, shown in Figure 1. These EoL algorithms are implemented in the visual programming environment Grasshopper 3D within Rhinoceros 3D and their connection to the architectural design model in ArchiCAD. It discusses the challenges of incorporating these EoL algorithms to enhance the effectiveness of circular design approaches to incorporate crucial data regarding building materials and their reuse potential, as well as Life Cycle Assessment (LCA) and EU taxonomy compliance (European Commission, 2024).

The paper is structured as follows: First, the methodology section reviews the different digital tools used and outlines the intended workflow between Grasshopper and ArchiCAD. Followed by illustrating in more detail the steps created in the EoL algorithms to generate the needed data flow between the programs. Finally, the paper discusses findings and suggests ways for further improvement in integrating these algorithms effectively.

Methodology - Data Integration for EoL- Algorithms

The method is an interdisciplinary research approach. A specific set of digital tools has been selected to facilitate the research objectives. ArchiCAD, employed as a BIM-model and digital planning tool (IFC data/OpenBIM), was selected not only because it is one of the most used digital tools in the AEC industry but also for its ability for efficient data storage and its inclusion of essential data required

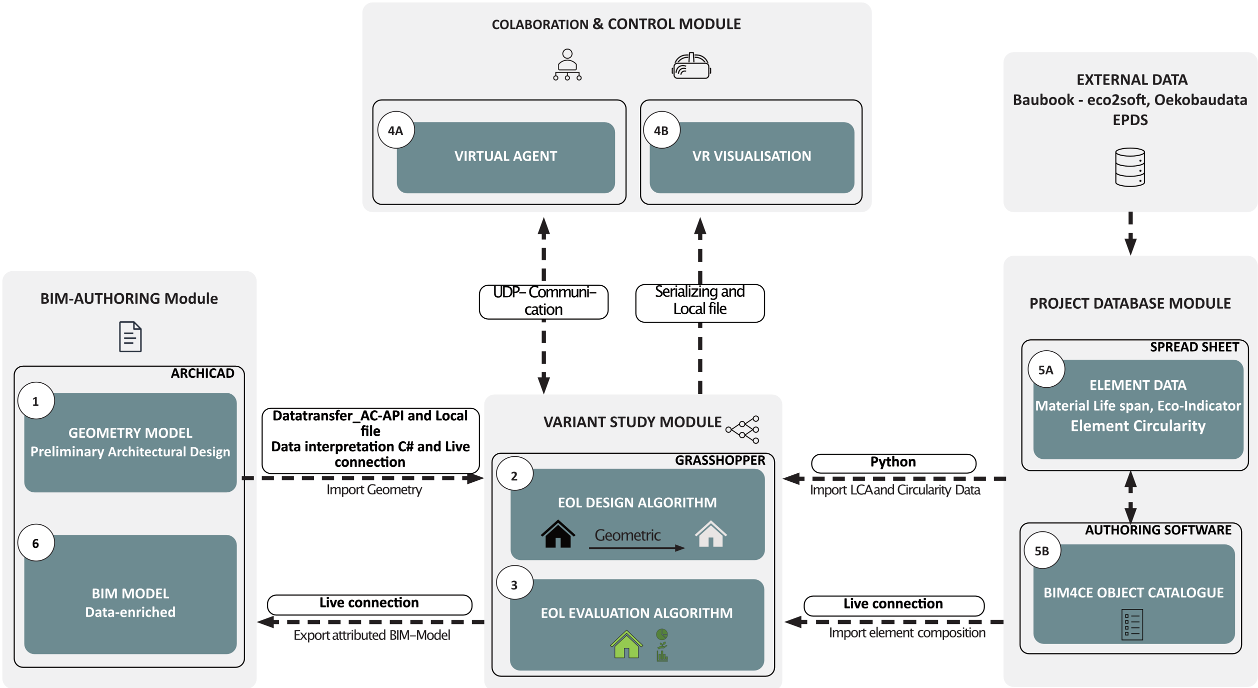

Figure 1: Overview of the proposed framework and software interfaces

for diverse Life Cycle Assessment calculations. Additionally, Grasshopper as a visual programming tool, with an established Live Connection to ArchiCAD (Graphisoft Deutschland, 2024), handling spreadsheet-based documents and including Python/C# script, has been incorporated because of its multifaceted benefits. Furthermore, Grasshopper enables the Virtual Agent in the VR platform to access and modify various components, a crucial requirement for this project. This selection of tools was analysed, leading to the development of an initial prototype of End-of-Life (EoL) algorithms by utilising these diverse interfaces. The conducted literature review led to assessment collection (LCA), which defined the necessary data and basic information and connections required to create the Grasshopper script obtained from the BIM model, are shown in Figure 2 and described below.

Data Input and Model Reconstruction

- Extracted from the architectural design model: Basic geometric data, the quantity of elements essential for subsequent calculations, and spatial reference line accurately generating the geometric twin in Grasshopper for access by the Virtual Agent in the VR platform.
- From ArchiCAD composites (products): The composite name, crucial for efficient product search within the spreadsheet-based object catalogue and the retrieval of accurate data for LCA calculations, and the dimensions of the (new) elements, necessary for precise volume calculations used in mass determination.

Using basic geometric data, the visual geometric twin of the preliminary architectural design is established within the Rhino/Grasshopper environment. This is achieved through the Grasshopper – ArchiCAD Live Connection (Graphisoft Deutschland, 2024) and direct model integration. Recreating the architectural design in Grasshopper is crucial because it cannot perform basic operations with ArchiCAD components. As a result, the geometric information must be filtered, and the model reconstructed accordingly in the Grasshopper environment.

Algorithm Development

a) EoL- design algorithm
After successfully incorporating the geometric form of the case study and the subsequent visualisation of the 'circular twin', the process continues with the extraction of design parameters derived from the data imported from the case study and the BIM-based object database created in ArchiCAD. This process uses several components from the ArchiCAD Plug-in within the Grasshopper environment while maintaining a live connection to ArchiCAD. This allows users to select different materials and compositions from the BIM object database to visualise and generate different variants of the initial case study.
b) EoL- assessment algorithm
In the following part, connecting the user-selected data from the EoL- design algorithm and assessment information, such as the Key Performance Indicator GWP(total) for an LCA calculation through an EoL- assessment algorithm, is essential.

Visualisation - Virtual Reality Integration

The visualisation aspect of the conducted research is not the main focus of this paper. However, it is essential to emphasise that during the development of the algorithm, we needed to consistently consider that the Agent within the VR platform, who interacts with the user, must be able to access and control changeable parameters in Grasshopper.

Framework

To better understand the implementation within the visual programming environment Grasshopper, Figure 3 displays a simplified version of the Grasshopper script and its structure, focusing on wall elements within a test building. Achieving a seamless intersection with the BIM model data required the utilisation of a custom Plug-in within Grasshopper, tailored to receive and process data from ArchiCAD dynamically via the bi-directional Grasshopper-ArchiCAD Live connection was necessary (Graphisoft, 2023).

The framework described will be further validated through its application to a specific use case, showcasing its practical utility and effectiveness in a real-world scenario. This use case involves an architectural design project where the integration of circular economy principles is paramount. By implementing the digital framework within this context, the seamless interaction between Grasshopper and ArchiCAD facilitates a comprehensive analysis and reconfiguration of wall elements, demonstrating the framework's capacity to adapt and optimise based on circular design criteria. This application not only highlighted the robustness of the custom Plug-in and bi-directional live connection but also underscored the potential of the developed EoL algorithms to significantly enhance the sustainability of architectural projects through informed decision-making and design optimisation. The following section describes parameter mapping, variant and assessment generation of our status quo.

Concept of Parameter Mapping

In order to integrate ArchiCAD element types, such as walls, facades, or columns, from the BIM model, it is necessary to manually select each architectural design element per type for every floor within ArchiCAD, done by right-clicking on the parameters used for including a collection of ArchiCAD element types. This method enables the user to subsequently change each element type on each floor separately. However, this initial step cannot be achieved using the Agent in the VR platform, as it cannot access components through right-clicks.

After successfully incorporating all elements, the subsequent phase involves extracting crucial information. The custom components within the ”Deconstruct” group of the Live Connection Plug-in were required to achieve this. Each element type parameter was linked to its corresponding ”Deconstruct” component to obtain further details, including Brep (Polysurfaces) and reference lines. The obtained information is used to generate new variants at the exact location and assemble the visual digital geometric twin of the architectural design by merging all ”Brep” outputs, which can be accessed by the Agent and displayed in the VR platform.

However, it turned out that retrieving the net volume, crucial for assessment methods, was not achievable using this method. Thus, a custom property set (CPset) had to be included within ArchiCAD to automatically retrieve the net volume for every element via the ”Get Property Settings” component in Grasshopper. This workaround enabled the inclusion of the missing geometrical data in the script to calculate the overall mass of the building design.

Notably, during the development of the Grasshopper script, to ensure the accurate functionality of new connections, minimise dataflow time, and maintain proper data structuring. Initially, the focus was on a single ArchiCAD element type (wall) and one floor. Later, the other ArchiCAD element types were integrated for each floor.

Concept of Variant Generation

The tailored Grasshopper component ”Composite” represents products from the current ArchiCAD project and is used to include a selection of products from the object catalogue in the algorithm, for which information is available for the evaluation calculation. In order to make it accessible to the Virtual Agent, it was essential to link components that the Agent could modify to the customisable information in the script. In this case, the Virtual Agent could use the ”Number Slider” to run through predefined products to select from a list, facilitated by the Grasshopper ”List Item” component.

Once all the required information had been imported and retrieved, it was used to generate new ArchiCAD type elements using the 'Design' group components to create new ArchiCAD elements, such as Walls or Columns along the acquired reference data, creating new design variations. Figure 3 shows a simplified representation of a variant in the Grasshopper environment.

Concept of Assessment Generation

The final segment of the Grasshopper script involved incorporating crucial data to evaluate the circularity potential and environmental impacts of the user-generated variants, such as environmental product declarations (EPDs) and material densities, which could not be retrieved through BIM (Honic and Wolf, 2023). The spreadsheet-based object catalogue based on material databases was incorporated through a Python script developed for the EoL- assessment algorithm. This script imports the density required for calculating the overall mass of the building, along with the net volume of the products obtained through the customised CPset in ArchiCAD. Additionally, it provides the necessary data for evaluating the designs in terms of the circular economy. The Python script contains the following inputs:

- The names of the new products of all the elements modified or not modified as a list.
- The location and name of the external spreadsheet-based database

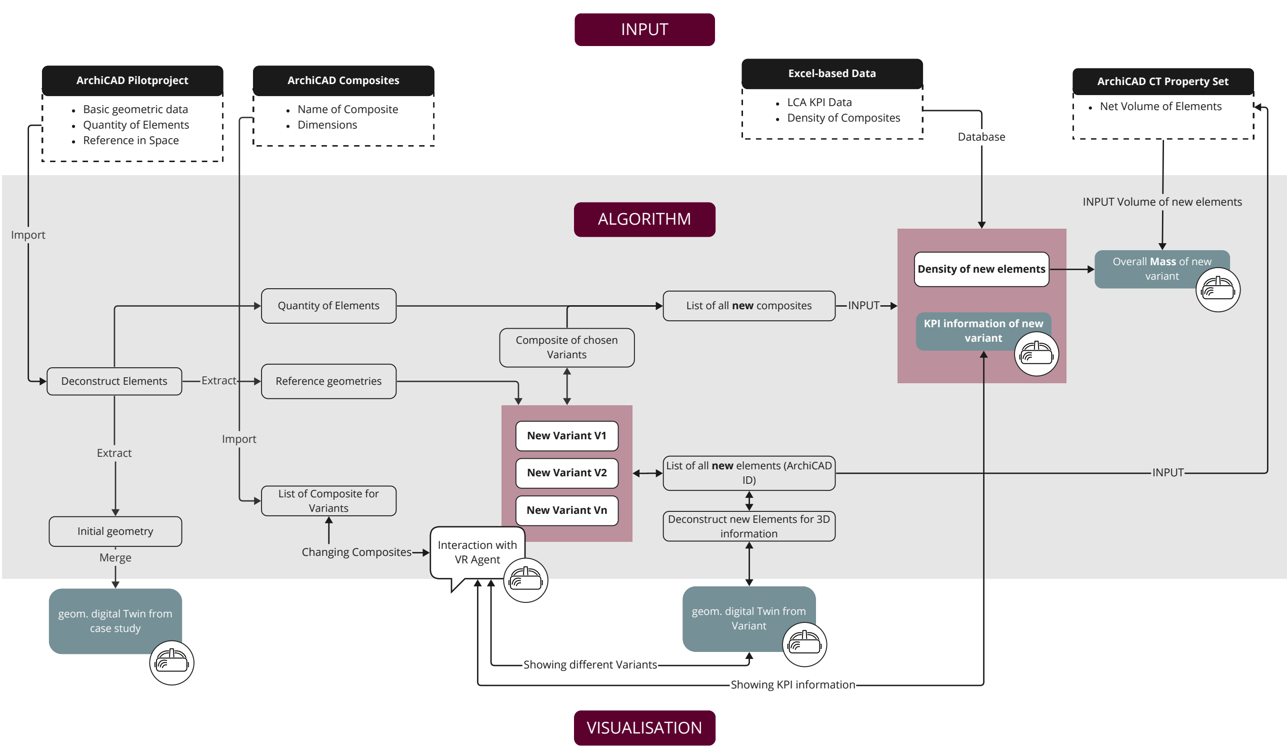

Figure 2: The process and data requirements to develop the EoL algorithms

- The Key Performance Indicator (KPI) the script should search for, e.g., Total Global Warming Potential (GWP - total) and the Material Density

Given the constant requirement for material density, the Python script has been duplicated. This allows the Virtual Agent to use a ”Number Slider” to modify the search input for the calculations in the first Python script while providing a stable estimate of the total mass in the second. However, the outputs of both scripts consist of lists outlining the requisite values for each product. Consequently, these lists must first be aggregated using the Grasshopper ”Mass addition” script before being made accessible to the Agent, enabling user visualisation in the VR platform.

Discussion

Throughout the development of the EoL- assessment algorithm, a consistent pattern emerged: the need for practical solutions to overcome various challenges concerning the interaction between the software used. These challenges primarily revolved around accessing and managing diverse data formats and flows.

One notable solution involved integrating spreadsheet-based circular economy assessment data and material density values using a Python script. This approach was necessary because of the inherent limitations of extracting such information directly from the BIM file (Honic and Wolf, 2023) using the Live connection and its ArchiCAD Grasshopper Toolset components or the customised CPset. Nevertheless, while effective, this solution revealed a vulnerability: the dependence on the spreadsheet-based file's location. However, having an external database for updates can be beneficial as more and more products on the market are expected to receive environmental information (baubook, 2024). This allows easy access to the latest data for design decisions and variant generation with the EoL algorithms.

To address the challenges associated with the extended processing time of the script, which arises from heavy data flow, including constant API interaction, visualisation of 3D elements, and execution of Python scripts for accessing and searching external data, the generation of variants becomes excessively time-consuming. To tackle this issue, exploring innovative approaches becomes imperative. One option worth considering is integrating the ” API - Grasshopper Plug-in” from (Wilk et al., 2023), which promises faster integration of the architectural design model and its data. However, as it relies primarily on textual input and output, it will require a hybrid script to ensure 3D visualisation in the VR platform.

Another challenge is the need for manual selection of ArchiCAD elements, as explained in the section ”Grasshopper Customisation - Parameter Mapping”. This requirement places a disadvantage on the user, requiring access to the Grasshopper script and understanding the basic concept and workflow of the EoL algorithms. However, one method currently under development involves a C# script in Grasshopper, connected via an Add-On in ArchiCAD, to collect and export the required data from ArchiCAD, which must be integrated into the developed algorithms structured according to the Grasshopper-script requirements. This approach would make the steps of

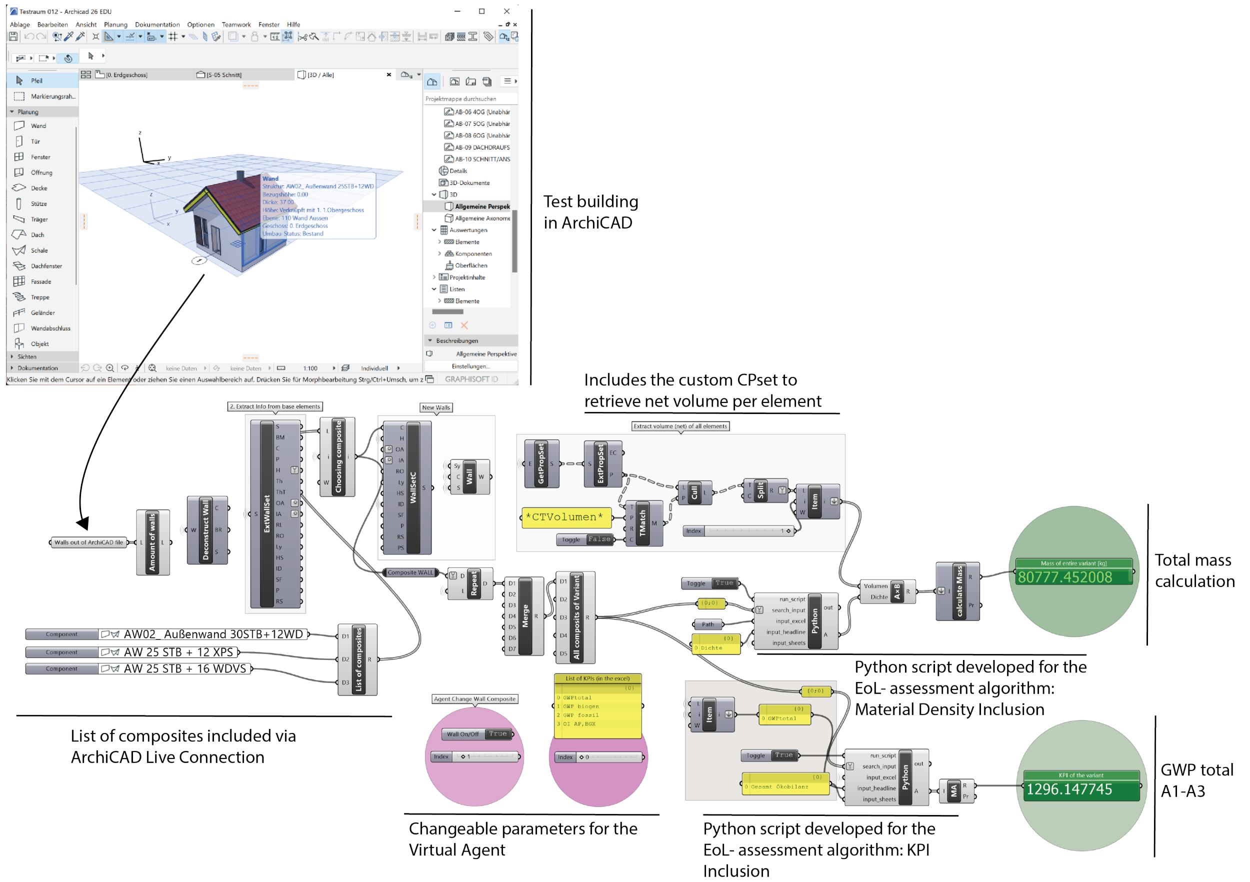

Figure 3: Simplified representation of the Grasshopper script using a test building focusing on four existing walls, showing how the mass [kg] and, in this example, the embodied carbon (GWP-total) for phases A1-A3 (product stage) [kg CO2e] are calculated

picking ArchiCAD elements manually per floor obsolete, enhance the script processing, and mitigate the risk of overlooking elements in ArchiCAD. It may improve user-friendliness, and other initial architectural designs can used.

Moreover, to increase the efficiency and versatility of the presented framework's application, the architecture model must be created following certain rules and structures. This involves the creation of specific ArchiCAD layers to more clearly distinguish between element types, such as internal and external walls. This step is essential due to the different structural functions of these elements and, therefore, different dimensions and product specifications. In addition, an ArchiCAD template should facilitate the seamless integration of the EoL algorithms into other architectural designs. However, it is important to note that doors and windows have been excluded from the EoL- design algorithm for this paper. This decision is due to the fact that the door/window ArchiCAD library part can only be accessed and modified by right-clicking on the ”Window Settings” component in Grasshopper, which is inaccessible to the Agent.

The complexity is additionally increased by successfully storing selected variants to ensure the comparability of generated design decisions. Whenever the Agent modifies the algorithm, the previously selected variant is replaced with the new one. In an initial attempt to address this issue and preserve the variants, a Python script was developed to save generated information through a repetitive loop. However, as the results of the loop were insufficient, either the Python script needs adjustment or an alternative solution must be pursued.

Table 1 outlines each limitation with its respective description and proposed future steps to address challenges that occurred during framework conceptualisation.

Conclusion

This paper outlines the possibility of automated decision support through EoL algorithms via a VR platform for design optimisation in terms of circularity and sustainability. It successfully implemented a case study and its building elements and obtained outcomes related to circular economy. While modifying the elements and generating a variant were successful, numerous technical and design challenges remain. However, assuming the intended changes and workarounds are well implemented, the potential for success is promising. It can provide a basis for further research to combine digital tools to better determine the feasibility of the respective interdisciplinary methods. This way, a computational approach and strategy for continuous environmental impact assessment in the construction industry can be developed. By addressing challenges head-

Table 1: Outline of limitations with descriptions and proposed future steps

Limitation	Description of Limitation	Future Steps
Integration Challenges with Diverse Data Formats and Flows	Managing and accessing various data formats between software tools presents significant challenges	Develop and implement middleware or APIs that can automatically translate and integrate data across platforms
Dependence on External spreadsheet-based File Locations	Utilising spreadsheet-based data for assessment data introduces a dependency on the file's location	Transition to cloud-based databases for dynamic access and updates, reducing reliance on static spreadsheet-based files
Extended Processing Time Due to Heavy Data Flow	The extensive data flow leads to time-consuming variant generation processes	Optimise algorithms for efficiency and explore parallel processing to manage and process data more quickly
Manual Selection of ArchiCAD Elements	Manual selection of elements in ArchiCAD for every floor adds complexity and time to the design process	Automate the selection process with AI or develop intuitive UIs that simplify and expedite the selection process
Structural Requirements for Architectural Models	Specific rules and structures must be followed for effective integration of EoL algorithms	Create templates and guidelines that standardise model structures, facilitating smoother integration
Exclusion of Doors and Windows from the EoL-Design Algorithm	Doors and windows are excluded due to limitations in accessing and modifying ArchiCAD library parts	Develop enhancements or Plug-ins for the VR platform to allow direct manipulation of doors and windows
Difficulty in Preserving Selected Variants for Comparison	Storing selected variants becomes complex when the Agent modifies the algorithm, leading to loss of previously selected variants	Implement a versioning system within the software that automatically archives and tracks changes to design variants

on and continuously iterating on the process, the EoL algorithms move closer to facilitating decision-making in the early design process, enabling circular building structures and integrating End-of-Life concepts.

Acknowledgment

The research described in this paper was carried out as part of the project ”Circular Twin - Ein digitales Ökosystem zur Generierung und Bewertung kreislauffähiger Digitaler Zwillinge”, funded by the Austrian Ministry for Climate Action, Environment, Energy, Mobility, Innovation and Technology through the Austrian funding agency (FFG), grant number 899167, which facilitated the conduct of this research.

ENTERPRISE DIGITAL TWINS FOR STRATEGIC DATA UTILISATION FROM CONSTRUCTION SITES

Abdulmalik Badamasi[1], Xiang Xie[2], and Mohamad Kassem[3]
[1]Newcastle University, Newcastle, UK

Abstract

The progressive digitalisation of construction sites, driven by the deployment of digital technologies, presents organisations with the significant challenge of effectively extracting value from the surge in data production. This paper introduces the concept of '*Enterprise Digital Twin*' (EDT) as a new form of digital enterprise in the construction sector, which extends beyond the scope of individual construction sites and projects to enable a variety of data-driven operational and strategic insights for construction organisation. Despite its importance, there exists a notable scarcity of research in this area. This paper introduces the EDT concept, presents a review of the available literature, proposes an early conceptualisation, and discusses its challenges and opportunities. These are early contributions to this nascent area and lay the foundation for future research.

Introduction

The construction industry is increasingly incorporating different digital tools and methods, such as Building Information Modelling (BIM), Wireless Sensor Networks (WSN), and Internet of Things (IoT) related technologies across the project lifecycle, including the construction phase (Statsenko et al., 2023). As a result, a large amount of operational data is produced in the construction industry and managed across geographically dispersed construction sites, supporting various functions such as procurement, quality assurance, supply chain, and logistics (Chen et al., 2024). Valuable insights can be untapped at both the project and enterprise levels through the exploitation and analysis of such extensive and diverse repositories of data, encompassing both structured and unstructured (You & Wu, 2019).

One of the pivotal technologies conceived for capturing and analysing data to deliver insights is Digital Twin. A Digital Twin (DT) is a digital replica of a physical entity, process, or system that enables a bidirectional information exchange between the digital and physical counterparts (Botín-Sanabria et al., 2022). Parvin (2021) stated that the information standard from enterprise to project is crucially important for digital twins to work in the construction industry. Research indicates a positive relationship between the degree of digitalisation of an enterprise through the use of DT and enterprise performance (Li & Liu, 2023). When augmented with other technologies, such as Internet of Things (IoT) and Artificial Intelligence (AI) , DT has the potential to provide real-time accurate status information and optimise ongoing design, plan, and production (Yitmen et al., 2023). Data integration is crucial because it allows businesses to utilise important operational data, which can yield new strategic and operational insights across diverse domains and functional areas. Yet, investigating how to effectively utilise this data from construction projects at the enterprise level is an emerging paradigm for both research and industry practice.

This paper explores the concept of EDTs within the construction sector. It highlights the necessity for EDT deployment and introduces a low-granularity conceptual architecture for EDTs. The methodology used to develop the EDT conceptual architecture is based on an extensive review of related concepts in literature and the guidelines established in existing reviews, such as this one. Furthermore, the paper examines the challenges associated with implementing EDTs, alongside the potential opportunities arising from their adoption.

Literature Review

Construction Digital Twin

Large contracting companies involved in major infrastructure projects usually manage construction projects with multiple geographically dispersed construction sites. Managing these construction sites at once within the same project can be challenging in terms of data generation, storing, processing, and visualisation (Hasan & Sacks, 2023). In the contemporary context, it is problematic that contractor organisations persist in relying on traditional methods to manage substantial volumes of data, owing to the absence of platforms capable of integrating data from diverse sources and types, making it very challenging to collect, manage, and exploit the generated data (Shamshiri et al., 2024). This is further challenged by the growing increase in size and complexity of data generated (Yan et al., 2020).

The collection of vast quantities of data also bears sustainability implications for the organisations involved. Storing large amounts of data in the cloud is not only expensive but also impacts the planet`s sustainability due to the emissions produced from data storage facilities (Vlăduțescu & Stănescu, 2023). The inadequate quality of visualisations and continued dependence on paper-based documents prevents managers and decision-makers from gaining clear insights and applying knowledge (Pan & Zhang, 2023).

Incorporating data into strategic management and decision-making processes can provide companies with numerous benefits (Ragazou et al. 2023). Although a large amount of data is available, many organisations fail to utilise it to their benefit (Ranjan & Foropon, 2021).

Digital Twin has emerged as a new technological concept that can address the management of smart construction site data for many reasons. DT has been adopted thus far only for a limited number of construction applications, and its concept has not been extended to the enterprise level. For instance, Sacks et al. (2020) proposed a comprehensive digital twin construction (DTC) system that integrates data from different activities to achieve closed-loop control systems. The DTC system extends beyond traditional activity-based monitoring and incorporates information from various sources. However, it is only activity-based and not operation-based. DT enables the integration of data, as highlighted by Salem and Dragomir (2022), indicating its role in integrating information technology and IoT for automating processes and managing activities related to building and urban structure operations. However, at the enterprise level, the exploration of this concept remains insufficiently addressed, with merely a handful of studies exploring its incorporation into Business Intelligence (BI) systems. For instance, Lopes and Boscarioli (2021) studied the implementation of BI and Analytics tools in the construction industry to improve management and decision-making. Rodrigues et al. (2022) studied the integration of BI with BIM in the construction industry, providing real-time data analysis for sustainable construction management and decision making. Thus, to address this important gap, in this paper we propose the introduction and early conceptualisation of the concept of 'Enterprise Digital Twin'.

The Need for Enterprise Digital Twin

The importance of DT at the enterprise within the construction industry presents unique opportunities and poses critical challenges. While digital transformation presents the potential to attain excellence, it is crucial to establish connections between digital technologies, information, and strategic decision-making in order to tackle construction challenges (Balzano & Marzi, 2023). Previous research has put forward the importance of establishing a sustainable innovation ecosystem for industry and enterprise knowledge management and practices by interconnecting technological innovation, the business model, and the market (Yan, 2015; Yun et al., 2017; Yang & Yan, 2019). However, the success of this proposition heavily relies on the ability of collecting the necessary data to generate insights. An enterprise level digital twin is conceived as a socio-technical paradigm with the ability of capturing data from diverse resources. Mêda et al. (2021) focused on the concept of an incremental digital twin construction (DTC) system, which aims to integrate data from different activities to achieve closed-loop control systems. Merino et al. (2023) proposed a method for integrating data from construction activities, Building Automation Systems (BAS), and IoT using federated data models and ontologies. However, these studies concentrated solely on activity-based aspects, excluding considerations of operational foresight and business intelligence. This study will discuss the Enterprise Digital Twin concept and its role in leveraging data from different construction sites and organisation operations in the generation of operational foresight and business intelligence.

Enterprise Digital Twin (EDT)

In the context of manufacturing, an Enterprise Digital Twin is defined as the utilisation of business-wide information to enable strategic decisions utilising asset and process digital twins across an organisation (Yan et al., 2022). Enterprise Digital Twins enable manufacturing managers to replicate all activities and interactions in the production chain, regardless of the number and location of assets, sites, suppliers, contractors, and sub-contractors involved (Kubelskiy, 2021). While some studies on EDT are available within the manufacturing sector, there exists a clear gap within the construction sector. This section introduces the concept of EDT in construction. EDT in construction is proposed as a virtual replica of an enterprise that incorporates people, processes, data, and technology to produce business outcomes. It is created by integrating technologies such as digital twins, cloud computing, analytics, artificial intelligence, and simulation.

An enterprise comprises multiple organisational units that collaborate to offer services that cannot be provided by a single organisational unit on its own. An Enterprise Architecture (EA) framework plays an essential role in defining principles and practices for creating and employing the information systems and technology infrastructure (Haki & Legner, 2021). EA frameworks form the foundation of the EA approach and serve the purpose of making the intricacies of the real world comprehensible and manageable for stakeholders (Scheer, 2023). Presently, various EA frameworks exist, including the Zachman framework, which was first introduced in 1987 as an early framework for EA (Zachman, 2003). Another prevalent EA framework is The Open Group Architecture Framework (TOGAF), which was initially developed as a methodology for the deployment of technical architectures but has since shifted its focus to EA over the years (Harrison, 2011). According to Riege and Aier (2009), Enterprise Architecture (EA) is widely recognised as an effective method for managing transformations and ensuring business/IT alignment. Therefore, an EA framework is employed in this research for initiating the early conceptualisation of EDT (Figure 1). This approach is guided by Zachman (2003) emphasis on addressing the what, how, when, who, where, and why aspects of information systems, mirroring the layers within the EDT conceptualisation that address the sourcing, integration, storage, analysis, and utilisation of data for decision-making in construction enterprises. Additionally, Harrison (2011) proposed that the Architecture Development Method (ADM) of The Open Group Architecture Framework (TOGAF) provides direction for developing architectures by following a series of stages, such as business architecture, information systems architectures, technology architecture, and others. A similar approach is mirrored in the conceptualisation of the Enterprise Digital Twin (EDT), where repetitive improvements are made at each layer to address the operational requirements of construction enterprises.

Data Source

Nowadays, data generation has become a prominent aspect across all types of construction activities, resulting in an increase in the volume of data that needs to be integrated (Alaloul et al., 2021). The data layer, which harvests information from IoT sensors and various other sources including models, programs, among others, in addition to organizational processes like procurement, estimation, and logistics, gathers extensive volumes of real-time, near-real-time, and static data. Such data is available from various sources on construction sites, such as IoT sensors, drones, BIM data, and project management software (Merino et al., 2023) and can be used to generate important foresights about the effectiveness and efficiency of construction operations (Wang et al., 2023). This data can include real-time performance metrics of machinery, worker productivity, material usage, environmental conditions, and more. For an enterprise digital twin, collecting high-quality, granular data is crucial as it forms the foundation of both the operational and business intelligence insights.

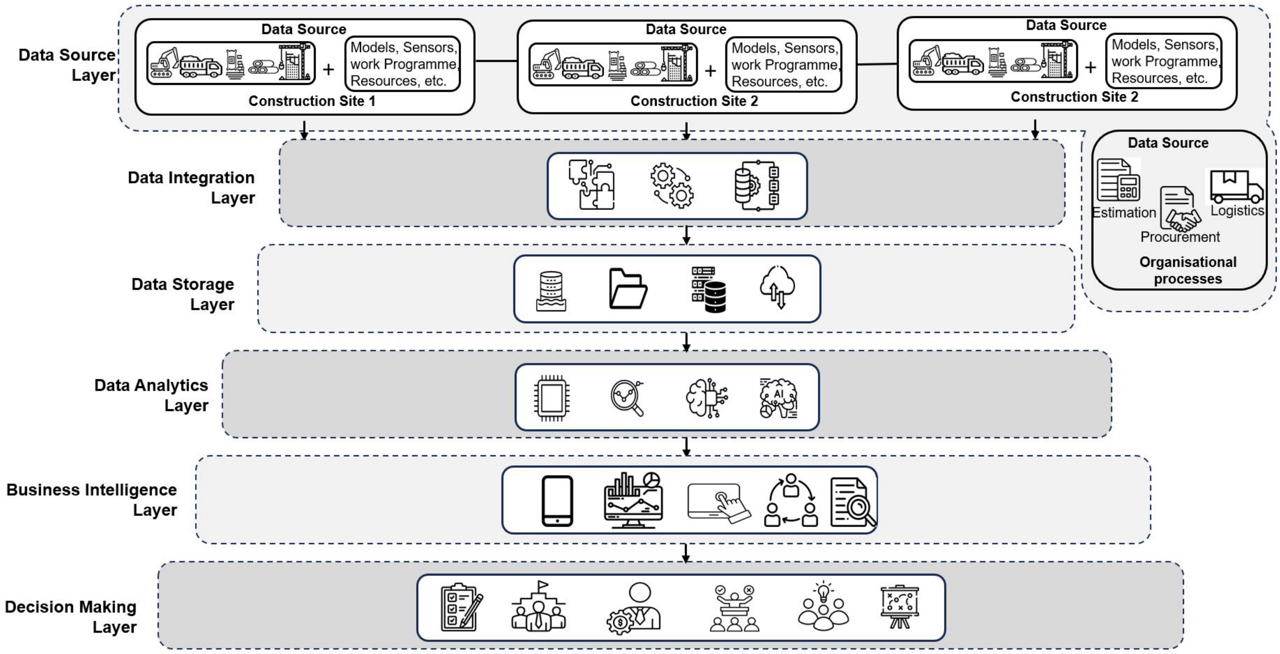

Figure 1: Conceptualisation of Enterprise Digital Twin

Data Integration

The significance of data integration is highlighted by Zhang et al., (2022) in the context of developing a digital twin that accurately mirrors the physical assets of construction sites. Within the context of EDT, the primary function of the data integration layer is to enable the seamless sharing and consolidation of data across various sources, ensuring that data and information is accessible, accurate, and consistent across the enterprise. Data integration layer has grown to encompass many different technologies and capabilities beyond Extract Transform Load (ETL) and ELT, which is just one-use case of data integration (Luengo et al., 2020), such as data virtualisation, data federation, cloud-based data integration services (e.g. Azure data factory, AWS Glue, etc.). These technologies are designed to gather, integrate, and transforms data from multiple sources into consistent, conformed, comprehensive, clean, and current information (Sherman, 2014). The data managed in the integration layer is critical to understand the status and performance of various enterprise components.

Data Storage

The data storage layer plays a crucial role in an enterprise architecture. It is responsible for persisting, managing, and utilising data within the organisation (Jones et al., 2022). Data warehousing is a data storage process that involves storing and preparing information separately from an organisation's routine transaction processing activities. It is designed to optimise the data for efficient access and analysis within the enterprise (Bharadiya, 2023). The layer in question serves as a repository for integrated data, including both structured data from data warehouses and unstructured or semi-structured data from data lakes. In this process, data from construction sites is transmitted to the data warehouse, where it undergoes data transformations such as cleansing, filtering, and aggregations that prepare the necessary to suit the enterprise required view of the data (Sherman, 2014).

Digital twin data, which are characterised by being sourced from multiple sources and having a large volume, necessitate the utilisation of big data storage technologies (Wang et al., 2023). The selection of a storage database for managing large amounts of data is contingent upon its ability to provide accessibility, scalability, high performance, and effective management. data storage solutions (e.g., cloud storage, database management system (DBMS), data warehouse and data lakes) are diverse, catering to different needs in terms of scale, performance, security, and accessibility. The selection of a data storage option is critical for supporting the varied applications and services an organisation relies on. Most studies have utilised cloud-based computing platforms for storing data which offer flexible and excellent backend access for computing applications (Betti et al., 2024). The scalability and flexibility provided by cloud computing enable the storage, processing, and accessibility of substantial amounts of data produced by the digital twin (Knebel et al., 2023). The selection of a data storage option is critical for supporting the varied applications and services an organisation relies on.

Data Analytics

The data analytics layer encompasses a suite of technologies, including Artificial Intelligence (AI) with Machine Learning (ML) as a subset, which are employed to conduct comprehensive analyses on accumulated data (Raschka et al., 2020). These technologies have become indispensable for organisations of all sizes and across all industries, as analytics and data-driven decision making have proven to be of paramount importance, enhanced decision-making is achieved through analytics and machine learning by offering practical insights derived from digital twin data (Arsiwala et al., 2023). Digital twin data can be utilised for multiple user services through advanced data analytics technologies. The utilisation of AI and ML technologies is important for the processing and analysis of data in the within the construction sector (Kazeem et al., 2023). AI and ML algorithms are indispensable for managing and analysing the substantial volumes of data produced by deep learning technologies (Kaur et al., 2020). These computational tools excel in discerning patterns and trends within datasets, thus enabling the extraction of pivotal insights (Bharadiya, 2023). DTs use AI/ML for predictive modelling, optimisation, and real-time monitoring, offering organisations valuable information for data-driven decisions and enhanced performance (Omrany et al., 2023). The analytics layer in an EDT utilises data analytics, AI, and ML algorithms to transform raw data into actionable intelligence to supports decision-making processes and identifies patterns and predictions. The processed data, which are supported by visualisation technologies (Wu et al., 2021), are ultimately accessible to end users in a straightforward and interactive manner through data visualisation.

Business Intelligence

The Business Intelligence (BI) layer aims to visualise information using tools such as dashboards and reports, transforming complex datasets into accessible formats that facilitate understanding and decision-making. Effective visualisation is a crucial component within the construction industry, as it plays a key role in facilitating communication and decision-making among team members (Lucchi, 2023). Lopes and Boscarioli (2021) highlights the role of BI in facilitating data-driven decisions, where stakeholders can quickly understand key performance indicators (KPI) and trends, enabling timely and informed decisions. One of the strongest aspects of digital twins is the ability to display sensor data in a virtual environment (Petri et al., 2023). Two commonly employed techniques for visualising digital twin data are colour coding in 2D and 3D schematics, performance dashboards, and time-series graphs, which are facilitated by visualisation platforms (Pal et al., 2023). Boje et al., (2020) posit that the implementation of data visualisation techniques in project management at smart and distributed sites alleviates the challenge of data inundation. According to Salem and Dragomir (2022), incorporating data from various devices and models can provide improved insights for enterprise decision-making through cross-checking and cross-referencing. For instance, visualisation tools in the EDT can be extended to enable an understanding of operations across all sites. This layer enables the evaluation of performance among different sites and the recognition of optimal strategies that can be implemented at the enterprise level.

Decision Making

The decision-making layer, on the other hand, is where strategic, tactical, and operational decisions are made based on the insights provided by the BI layer and other sources. Yue (2023) describes how the decision support ecosystem consumes analytical insights with business goals to guide decision-making. The decision support system (DSS) employs the results from business intelligence (BI) tools, such as dashboards and reports, to guide decisions that align with the company's strategic plan. This involves not only analysing past data but also utilising predictive analytics to forecast potential future scenarios. The system aims to provide a comprehensive view of the enterprise's operations and enable informed decision-making that supports the company's long-term goals (Yue, 2023). The abilities provided by these allow decision-makers to predict potential problems, assess alternative solutions, and take measures. Yan et al. (2022) highlight its impact on strategic planning, where predictive insights can shape the direction of construction projects and broader enterprise initiatives. They argue that predictive insights derived from the digital twin's analytics can significantly influence the planning and execution of construction projects. For instance, by predicting the impact of various factors on project timelines and costs, enterprises can make informed decisions that optimise resource allocation, mitigate risks, and enhance overall project outcomes (Yan et al., 2022). Sacks et al. (2020) state that the insights derived from the lifecycle of the digital twin significantly contribute to operational excellence and competitive advantage. Therefore, the digital twin at the enterprise level can become an indispensable tool for continuous improvement and strategic decision-making using data from across smart construction sites and business functions.

EDT: Challenges and Opportunities

The implementation of EDTs in construction projects involves different technical challenges that need to be addressed to fully leverage their capabilities. Construction projects often generate large amounts of data in different formats due to the application of various systems and technologies (Himeur et al., 2023).

Advanced data management and interoperability solutions are necessary to integrate this data into an interconnected digital twin. The challenge is made more difficult due to the requirement for timely updates of data to keep the digital twin accurate and relevant (Borrmann et al., 2015). The potential to address this challenge lies in the adoption of recognised and accepted formats (such as XML, CSV, IFC, JSON, etc.) and protocols for storing and exchanging data that ensure compatibility and ease of use across different systems and applications employed by organisations in construction projects. However, as organisations pursuing EDTs are likely to be face complexity and scale challenges, standardisation, and integration across the various areas of the business become key (Faith and Tori, 2020). Semantic Web concepts such as the Enterprise Knowledge Graphs (EKG), a formal model to represent and manage enterprise information at a semantic level, can play a key role in integration.

Privacy issues emerge when encountering confidential data regarding project sites, designs, and staff members (Zhang et al., 2022). The nature of the data gathered and utilised by EDTs may encompass sensitive information, giving rise to issues regarding individuals with authorised entry to such data and the way it is used. Defining the roles and responsibilities for data management and ensuring compliance with relevant regulations can assist in mitigating privacy concerns by instituting well-defined policies for data access, usage, and sharing (Coupaye et al., 2023).

Security is an additional issue in relation to EDTs, as these digital systems are susceptible to cyber threats, like any other digital system (Faleiro et al., 2022). Potential interconnectedness between digital twins can present a major security risk, as a breach in one system has the potential to compromise the entire network, making it susceptible to cyberattacks (Faleiro et al., 2022). Protecting EDTs from such threats requires the implementation of advanced cybersecurity measures, including encryption, secure data storage and transmission protocols, and regular security audits (Lu et al., 2017). This includes the use of firewalls, intrusion detection systems, and regular vulnerability assessments by organisations.

Overcoming technical challenges and addressing organisational challenges are both necessary to leverage EDTs in the construction industry. The workforce must possess a high level of digital literacy and technical skills owing to the intricate nature of DTs (Hou et al., 2020). This encompasses proficiency in data analysis, an understanding of digital twin software and platforms, and the ability to comprehend and act upon the insights provided by DT at the enterprise level (Himeur et al., 2023). To address this challenge, it is necessary to implement training programs and recruit individuals with the necessary digital skills. Moreover, fostering a culture that promotes continuous learning and adaptation to stay abreast of technological advancements is important (Howard et al., 2017).

EDTs require organisations to develop and implement customised training programs to enhance the digital proficiency of their existing workforce and acquire new talents to address potential gaps in competencies (Agrawal et al., 2023). Continuous training is essential to maintain relevance in the face of fast-paced technological advancements. Implementing EDTs in construction initiatives frequently requires changing normal procedures and operational patterns (Riss et al., 2020). One approach to improving project management is to incorporate real-time data analysis and decision-making, as well as utilising the digital twin's predictive capabilities to refine procurement, scheduling, and risk management processes (Ragazou et al., 2023). Finally, due to the likely need for process reengineering that have the potential to cause disruptions and face opposition, the transformation require effective leadership and transparent communication regarding the advantages to all parties involved (Müller et al., 2024).

The implementation of EDTs in the construction industry presents many opportunities for innovation, construction practices, and the development of new business models (Kulkarni et al., 2019). New business models can be developed by leveraging the insights and efficiencies obtained from EDTs. Construction firms can enhance their value proposition by providing data-driven services that diversify revenue streams and foster long-term client relationships by offering value beyond project completion. For example, EDTs facilitate the construction of sustainable buildings by improving planning and resource allocation. The optimisation of energy use, selection of sustainable materials, and integration of renewable energy sources into new projects can be facilitated by EDT, thereby aligning with global sustainability goals (Riss et al., 2020).

To take advantage of these opportunities, construction companies need to cultivate an environment that encourages innovation, collaboration, and standardisation, that are key enablers to transformative projects (Hook et al., 2022) such as EDTs. They also require exploring partnerships within their supply chains to enhance the connectedness that is key to EDT as well as allocating the resources to acquire essential technologies and develop and acquire the necessary competencies.

Conclusions

The concept of Enterprise Digital Twins (EDTs) in the construction industry is emergent, driven by the exponential increase in data availability due to the widespread adoption of digital technologies on construction sites and beyond. Recognising the emergent nature of EDT within the construction industry, this paper attempted to provide a balanced perspective about EDTs. The paper presented a low-granularity architecture model with six layers for EDTs for construction organisations. It highlighted the importance of EDT in the transition towards a more interconnected and data-driven method for managing and executing construction projects and organisations. It also outlined some key challenges such as interoperability, privacy, and security, as well as some of the organisational challenges.

Virtual and Augmented Reality

ON-SITE VISUALIZATION USING BIM AND EXTENDED REALITY

Kaja Pevec and Zoran Pučko
University of Maribor, Faculty of Civil Engineering, Transportation Engineering and Architecture, Slovenia

Abstract

The BIM approach is gaining significant attention in Slovenia's construction industry, soon becoming legally mandatory for publicly funded projects. Our study focuses on merging Building Information Modeling (BIM) and Extended Reality (XR), particularly Mixed Reality (MR), to improve construction processes. Focusing on the device Trimble XR10 with HoloLens 2, the visually compliance of the plans and the BIM model with the actual situation on the construction site was monitored. Additionally, a survey involving participants from local construction firms assessed user experiences with the device and contributed to analyzing advantages and disadvantages of traditional versus advanced approach (BIM and MR).

Introduction

Due to the increasing digitalization around the world, and consequently also in construction, there has been an heightened focus on advanced technologies such as BIM and XR. In Slovenia, the impending legal mandate for BIM implementation in publicly funded projects has spurred discussions on the industry's readiness and the potential benefits of integrating these technologies. The introduction of these technologies and devices faces many barriers, such as traditional mindsets, a culture of mistrust, limited knowledge of the workforce, low awareness of advanced technologies, complexity of the approach, the need to upgrade IT infrastructure, and it is therefore necessary to illustrate the benefits for construction companies. From the literature review (Alizadehsalehi et al., 2020; Safikhani et al., 2022; Sidani et al., 2021), research mainly conducted in the design and operational phase, off-site, by architects and real estate agents, and includes 3D models for visualization for owners, where VR and AR technologies predominating. AR is used during the construction phase to visualize and train workers. MR, which enables the merging of the virtual and real worlds and has the greatest potential for interactive collaboration between stakeholders on the construction sites is rather underrepresented. Our study delves into the practical implications of combining BIM and MR, specifically utilizing the Trimble XR10 helmet with the HoloLens 2 visor (*Trimble XR10 with HoloLens 2*, 2019), to enhance visualization on construction sites. Visualization is becoming a trend in the construction industry, as it enables easier understanding when monitoring construction projects and processes. With the help of advanced technologies such as AR (Augmented Reality) and MR (Mixed Reality), visualization on the construction site is more practical and efficient. An experiment was conducted on the construction site of the Retirement Home Šmarje pri Jelšah – dislocated unit Kozje, involving the creation and placement of a customized 3D BIM model with the advanced devise. The Trimble Connect AR + MR program ("Trimble Connect AR + MR," n.d.) was used for the experiment. Simultaneously, in order to compare the advanced and traditional approach in construction projects, a survey was conducted, involving 25 employees from local construction firms to capture user experiences with the advanced device and opinions on advanced approaches in construction, including the answer to the question of whether it makes sense to invest in advanced devices.

On-site visualization

Visualization

Visualization means creating a visual representation of information for easy understanding and interpretation. Visualization with the help of computer graphics and image processing enables the visual representation of forms and processes that we perceive and imagine more easily. With new technologies, immersive visualization has also appeared, which enables users to have an in-depth experience with the help of various interfaces, screens and devices. By combining enhanced sensory perception and tangible interaction, immersive visualization aims to reduce the user's perception of the real world so that their attention is focused solely on the immersive, non-real environment, thereby improving analytical and decision-making skills. This is where extended reality technologies come to the fore. By using immersive or advanced devices, it is possible to provide users with multi-sensory feedback that allows them to perceive experiences that closely resemble reality. Through sensory channels, the sense of control and realism increases for users, which usually improves the efficiency of users in obtaining data (Zhang et al., 2023).

BIM approach

Saving time, costs and improved collaboration between project participants can be achieved by collecting information about the project in one place, accessible anytime and anywhere. The above is a simplified definition of the BIM approach (Sacks et al., 2018). BIM stands for Building Information Modelling and it is a process supported by a number of tools and technologies that involve the creation and management of digital representations of the physical and functional properties of the built environment (Marc et al., 2018). In the research two dimensions of BIM, namely 3D and 4D BIM were used. 3D BIM is a geometric model of a building, which captures all the geometric data of the model and the individual building asset in an interconnected manner. The 4D BIM dimension is the 3D BIM model upgraded with a specific time dimension, with a time schedule for the construction of the building asset of the BIM model. For the purpose of the experiment, a basic 3D BIM model of the building was obtained and adapted to facilitate the treatment with the advanced device. In the practical part, a 3D BIM model over time (sequences) using MR, were presented, which already mainly belongs to the field of 4D BIM.

Extended Reality

XR is a technology that combines both the digital and the real world. It augments the physical world with digital/computational elements using advanced devices. It is divided into three types: VR - virtual reality, AR - augmented reality and MR - mixed reality. VR is a technology that creates a virtual, digital environment. AR allows digital elements such as graphics, sound to be added to the real world. Virtual elements are placed in the real environment through interfaces, enriching it, while the user still maintains contact with the physical environment. MR is a combination of VR and AR, combining the real and virtual worlds. It allows the integration of virtual elements into the real environment. This technology allows the user to interact with digital elements in a real environment while maintaining awareness and contact with the real world. MR is a great tool for good on-site visualization in combination with the BIM approach, which will be presented in the next section.

Experiment

The case

The building under consideration, the Retirement Home Šmarje pri Jelšah – dislocated unit Kozje, is designed in a semicircular form, with three floors and comprises 2555.47 m^2 of net usable floor area. The foundation slab, the intermediate floor slabs and external walls are of reinforced concrete. The internal walls are of brick construction. All partition walls in the building are dry-walled - a system of two-layer plasterboard panels in a metal substructure with mineral wool insulation. The roof structure is a reinforced concrete panel. The building is designed to accommodate 49 residents. It is designed as a zero-energy building according to the Design&Build principle. The 3D BIM model of the building is presented in Fig. 1.

Figure 1: 3D BIM model of the building

3D BIM model preparation

The 3D BIM model of the building in question contains only the structural elements and interior fittings, without the necessary installations, with the focus on the individual structural elements when monitoring the progress of the work on site with the advanced device. For further consideration of the building model and placement in the space, the model was scaled down as the full model file was too large to export and use on an advanced device. For the purpose of this paper, the limitation is given to the first floor and therefore all unnecessary elements have been deleted in the 3D BIM model. The ArchiCAD program was used to edit the model. For greater visualization or transparency of the layout of the 3D BIM model on the location in a 1:1 scale, the mezzanine panels with the terrace were also removed. The other elements on the first floor were preserved. The lift shafts are visible in their entirety, as they were created individually as one element. Fig. 2 shows the adjusted 3D BIM model of the building's first floor displayed in the Trimble Connect program.

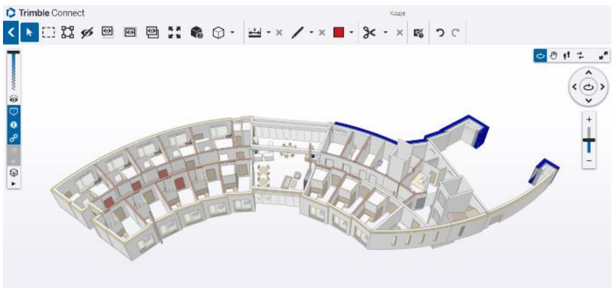

Figure 2: Customized 3D BIM model of the first floor

Equipping a 3D BIM model with a QR code

To facilitate the placement of the 3D BIM model in the real environment, a QR code or marker needed to be generated using the Trimble Connect software tool. The software generates a unique QR code, which connects to the advanced device while using the application Trimble Connect MR+AR. One or more QR codes can be generated for a single 3D BIM model of a set of elements or an object. For an easier determination of the location of the sheet with the QR code on the construction site a starting point on the 3D BIM model was chosen (presented in Fig. 3).

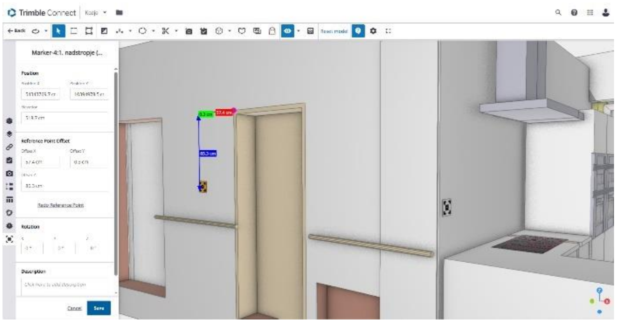

Figure 3: QR code locations and determining the starting point

The QR codes were printed in 100 % custom ratio and attached to selected locations on the object (see Figure 4). When placing the QR code on real elements, it is important to correctly determine the starting point, which was predetermined in the software, and place the lower left edge of the QR code exactly at this point. This requires a flat and clean surface to attach the QR code, taking into account orthogonality and using a quality mounting agent.

Figure 4: Attached QR codes on the building

Model placement in a real environment

An advanced device to carry out the experiment on site was used. The Trimble XR10 with HoloLens 2 is an advanced device that uses extended reality technology to bring digital elements from the screen into the physical world and clearly present the work of all participants, allowing projects to be completed on time and at no extra cost. It is the product of a successful collaboration between Microsoft Corporation and Trimble Inc. The device consists of two parts (see Figure 5) the Trimble XR10 protective work helmet and the HoloLens 2 visor.

Figure 5: Trimble XR10 with HoloLens 2

The Trimble Connect AR+MR application allows you to place a 3D BIM model into any environment in several different ways, in different sizes and views. It can simply open the model in the application and place it in any place, in any scale. Figure 7 illustrates the basic display of the entire 3D BIM model of the building on the construction site. For better accuracy and faster placement of the model on the construction site, the "Marker" subcommand was used, to scan the previously prepared and pasted QR code on the building. The model placement process is shown in Figure 6.

Figure 7: Display of the entire 3D BIM model of the building with its surroundings on the construction site

The first step was choosing the subcommand “Marker” in the menu of the advanced device. Then, with the help of the camera integrated in the advanced device, the QR code was scanned and uploaded a digital 3D BIM model using MR technology and projected it in a real environment. This allowed us to place the model on a real object at 1:1 scale. In the process of integrating the 3D BIM model at the construction site, occasional inaccuracies arose in projecting and aligning the model with the real structure, resulting in maximum deviations of 10 cm, when aligning along a non-straight wall. The minimal misalignment was observed when positioning the model using a QR code.

Preparation of the Sequence

Sequences in the Trimble Connect desktop application were created to show the construction phases of each structural element on the first floor of the building. One sequence will be presented in more detail in a selected room on the ground floor of the building in question (presented in Fig. 8). The sequence consists of seven steps (Fig. 9-15) and shows the construction of the vertical structural elements of the room in question according to the prepared 3D BIM model. The first step is the construction of the external walls, the second step is the construction of the internal brick walls, followed by the third step of the plastering. The fourth step is the installation of the internal panels of the internal drywall for the bathroom, the fifth step is the installation of the insulation on the drywall, the sixth step is the construction

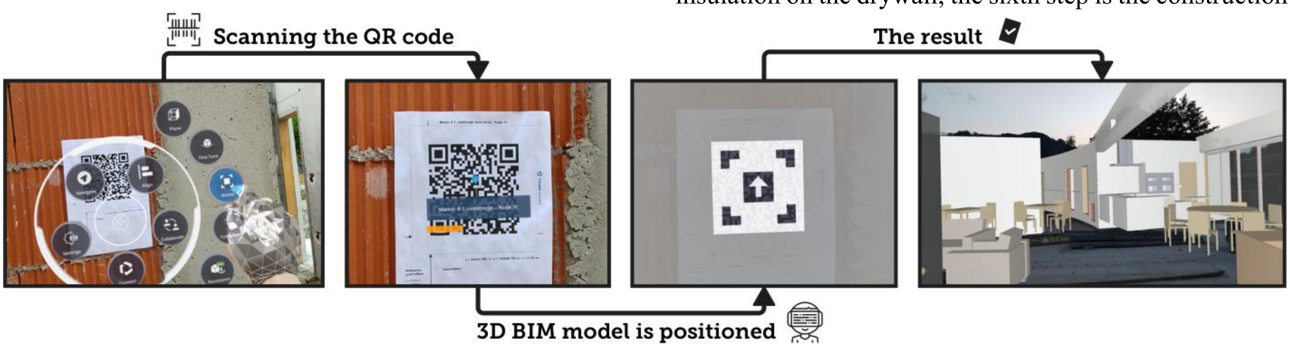

Figure 6: The process of placing a 3D BIM model with a QR code in a real environment

of the external panels of the internal drywall and the last step is the fixing of the tiles on the drywall in the bathroom. The sequence does not take into account the additional steps in the construction of the external wall (formwork, concreting, dismantling formwork), but is shown in one step, as “the construction of the external walls” (Fig. 9). The selected elements are shown and labelled individually in the figures, step by step, while the remaining elements are hidden. If a sequence were to be played, each previous element would remain displayed. For better understanding, each step and its corresponding element has been marked with a specific color, e.g. walls are marked in green.

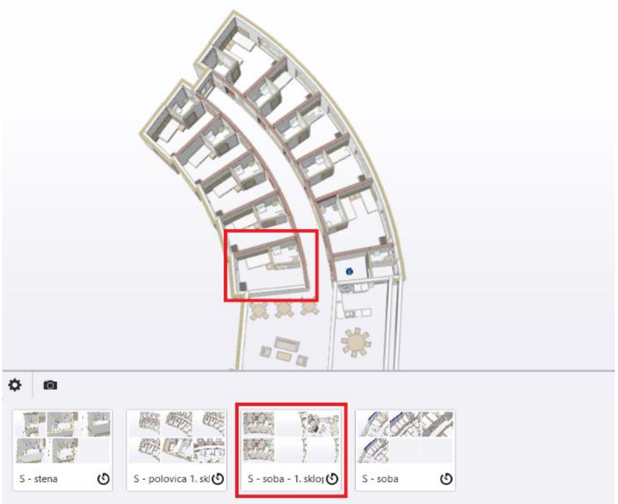

Figure 8: Selected room and sequence in the 3D BIM model

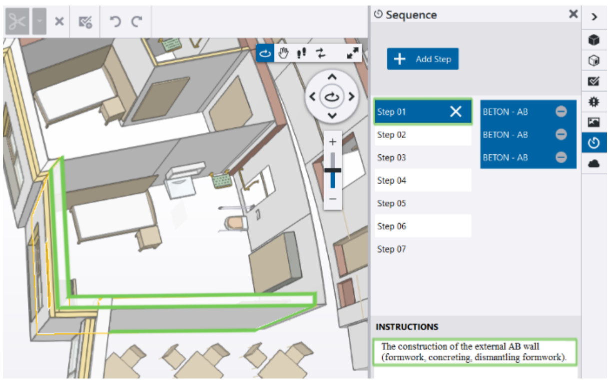

Figure 9: Step 1

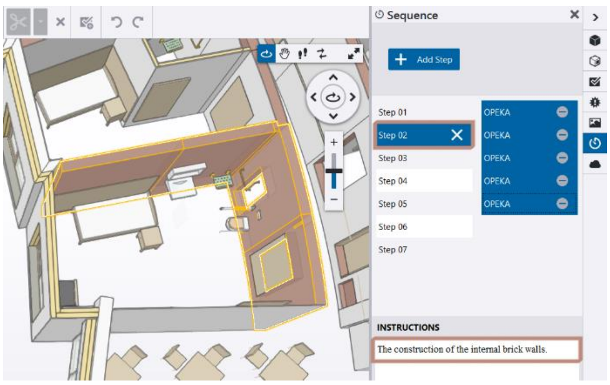

Figure 10: Step 2

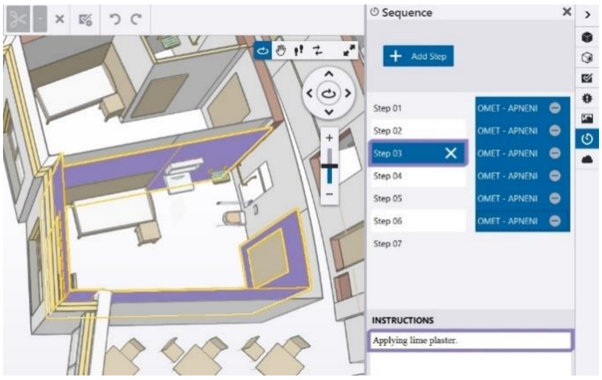

Figure 11: Step 3

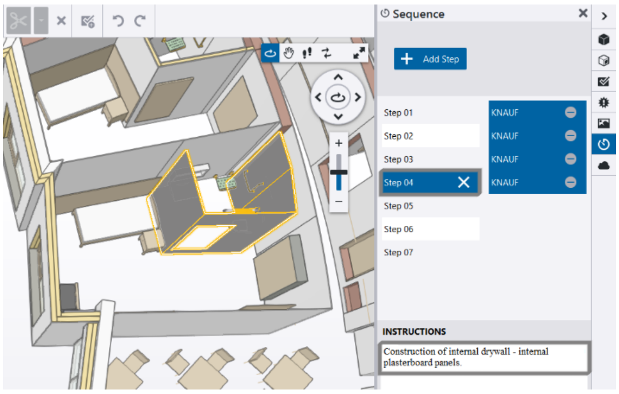

Figure 12: Step 4

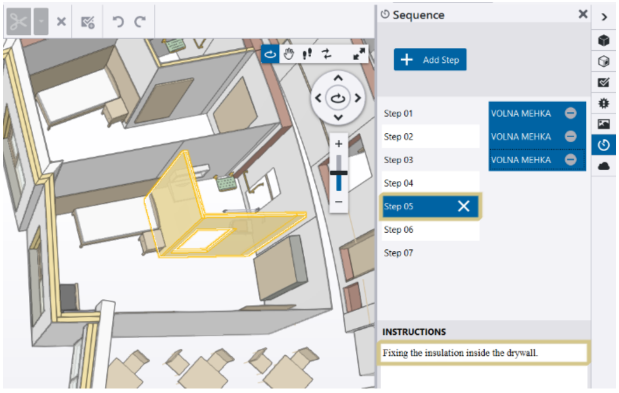

Figure 13: Step 5

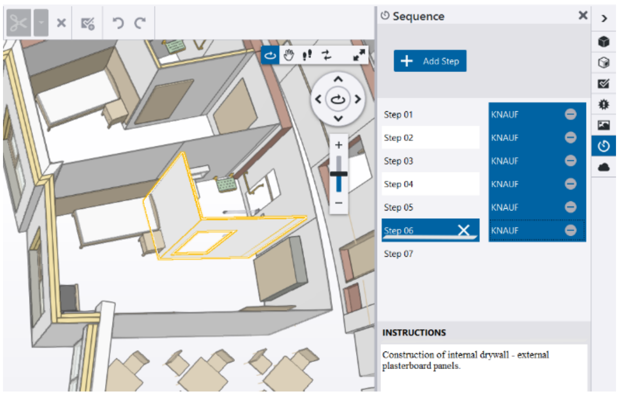

Figure 14: Step 6

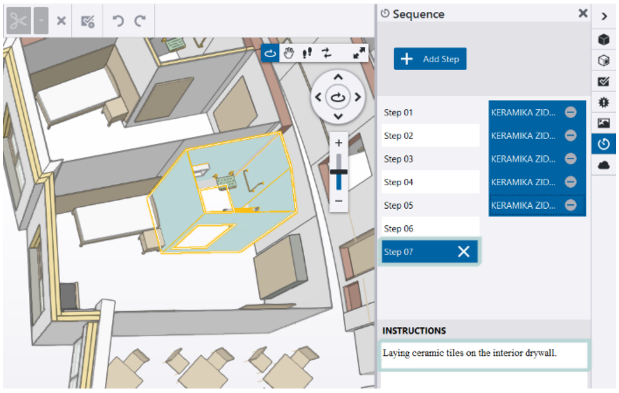

Figure 15: Step 7

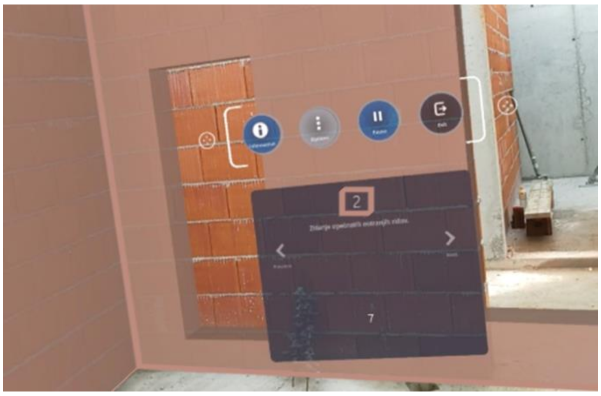

Figure 17: Step 2 of the on-site sequence

On-site sequence display

In the previous subsection Preparation of the Sequence, the construction sequence of vertical construction elements of one room on the first floor of the building was demonstrated. In the following, the sequences will be shown on a 3D BIM model with the advanced device on the construction site.

The sequence is displayed in a real environment by selecting the command "Sequence" in the basic menu of the Trimble AR+MR application and then selecting the desired project, model. After the basic placement of the model, the "Collaborate" command and the "Sequence" subcommand were selected. A window appeared showing the steps of the selected sequence. You can move the steps manually or play the sequence. Visualization of the individual steps of the sequence on the construction site is shown in Figures 16-22 below. Each displayed 3D element of the sequence step is colored with a specific color, as in the previous subsection. On the model, a hole in the bathroom is present where the purpose is to show the area where the installation will take place and be kept. This hole was subsequently made on the building, but in a smaller size. It is also visible that the balcony and entrance doors in the model are placed higher than the actual floor, as the remaining materials and elements on the floor have not yet been installed.

Figure 16: Step 1 of the on-site sequence

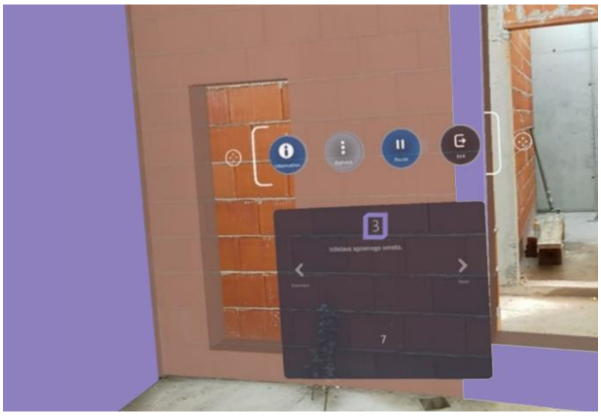

Figure 18: Step 3 of the on-site sequence

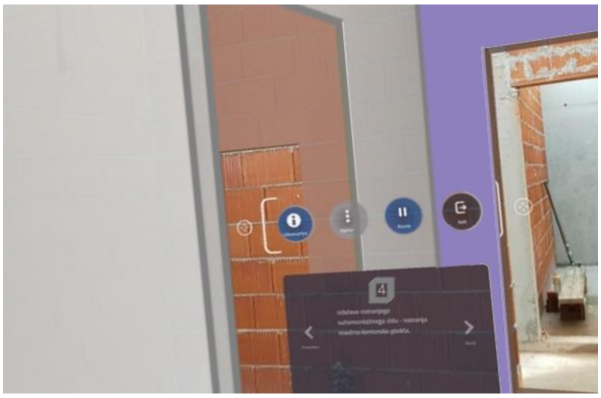

Figure 19: Step 4 of the on-site sequence

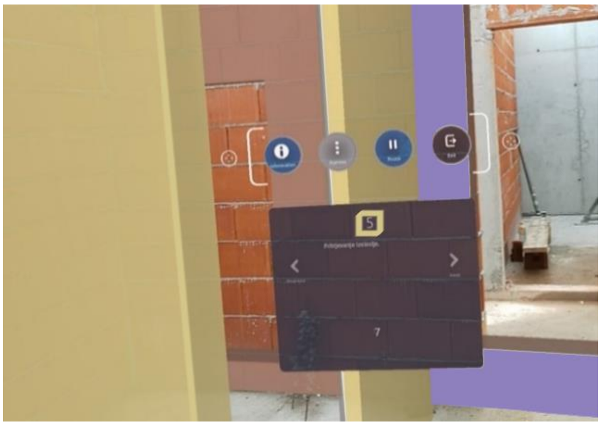

Figure 20: Step 5 of the on-site sequence

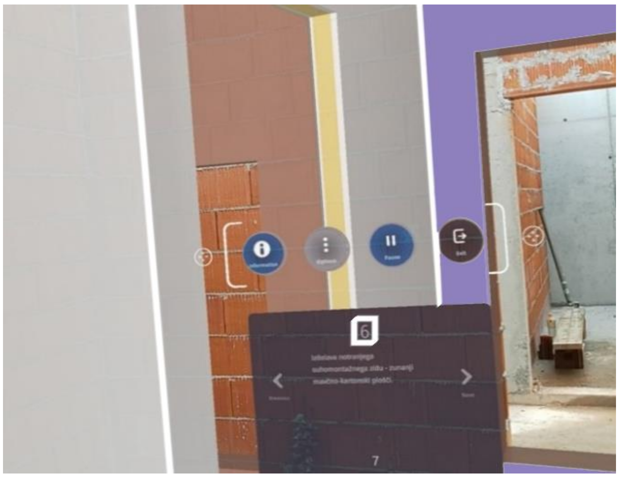

Figure 21: Step 6 of the on-site sequence

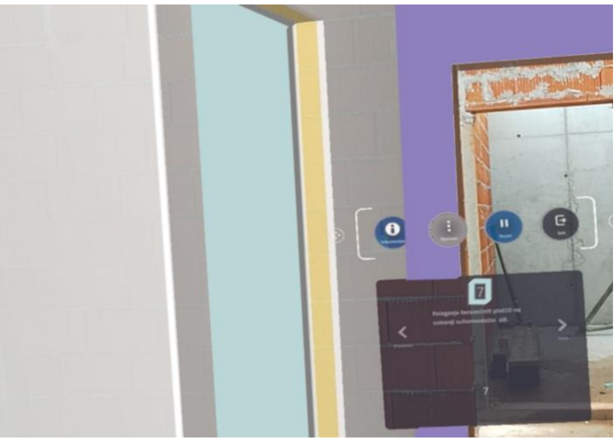

Figure 22: Step 7 of the on-site sequence

For an easier presentation and understanding of the sequence in a real environment, some steps of the sequence (steps of construction elements, without final cladding), through the construction process of the actual building, on the construction site are presented in Figure 23. These steps are: construction of the RC external walls (1), internal brick walls (2) and internal drywalls (4&6).

After the first two steps, work on the construction site continued on the second section of the first floor, where the vertical structural elements were constructed. Then the work for the installation of the slab between the floors was carried out. The next step of the sequence started after the construction of the external and internal walls on the second floor has been completed.

Figure 23: Steps 1, 2, 4 and 6 of the sequence shown with the actual object (Source: Josip Pongračić)

Survey

The traditional approach of looking at plans and monitoring progress in the field has started to be replaced by a modern approach using advanced devices such as the Trimble XR10 with HoloLens 2, which allows the projection and interaction with digital models in real time, in a physical environment. In order to gain insight into the user experience of construction employees for this device, a survey was conducted to obtain relevant information on the pros and cons of the advanced device and to determine the rationale for use and investment. For the purpose of the research, a questionnaire was prepared, entitled "The use of advanced devices for extended reality in construction projects". At the time of the experiment, there were 40 workers at the construction site who were invited to try the Trimble XR10 with HoloLens 2. 15 individuals refused to participate, while 25 took part in the survey, representing 62,5 % of those invited. The questionnaire consisted of 14 closed-ended questions and one open-ended question. For the six questions on user experience, a 5-point descriptive scale, the Likert scale, was used to better analyze the responses. The results were then processed and displayed in Excel. In the following, the findings and the analysis of the respondents' answers will be presented.

The first four questions related to the general analysis of respondents' statistics: age, education, type of employment and workplace. 25 people took part in the questionnaire, 20 male and 5 female. This can be attributed to the fact that more male workers are employed in the construction sector due to the physical labor involved. Of all respondents, 10 have completed secondary school, 5 have completed a master's degree, 3 have completed a vocational or professional higher education, 2 have completed a bachelor's degree and 2 have completed primary school. None of the respondents had completed a PhD or other course. When asked about the type of employment, the majority of respondents answered that they were in regular employment, only 4 were in student services, 2 were self-employed and 1 answered contract work.

Since the paper focuses on visualization on the construction site, the type of employment of the respondents is also interesting. In order to get as diverse answers and opinions as possible, several different professions in the construction industry are covered in the survey. Most respondents (36 %) chose the answer "Other" to the question "Job" and gave the following answers: architectural engineer, mechanical engineer, mechanical development engineer, independent purchaser, electrician, IT technician (2 persons), blacksmith and project associate. 28% of all persons surveyed were site workers, followed by civil engineers or project managers with 12%. Two persons were foremen and one person was a supervisor.

The fifth question was: Have you had any experience with VR/AR/MR devices before using an advanced device? 72% of the respondents (18) had no previous experience of using VR, AR or MR devices prior to using the Trimble XR10 with HoloLens 2. This was the first time that the majority of the respondents had seen and used an advanced device in person and were familiar with new technologies in construction.

Table 1 below shows the results of the level of agreement with the statements related to the respondents' user experience using the Trimble XR10 advanced device with HoloLens 2. The statements related to the ease of use of the advanced device, the comfort of wearing the advanced device, how satisfactory the display and sound is, whether the device responds well to commands, and the perception of the usefulness of using the device on the construction site. Each statement was rated on a 5-point descriptive scale, where I don't agree at all, 2 is I partially agree, 3 is I neither agree nor disagree, 4 is I agree and 5 is I strongly agree. The columns for each statement show the number of respondents and their proportion of each answer, the level of agreement.

Table 1: Respondents' user experience with the advanced device

5-point descriptive scale	1	2	3	4	5
	Number (%)	Number (%)	Number (%)	Number (%)	Number (%)
It is easy to use.	0 (0 %)	2 (8 %)	8 (32 %)	**10 (40 %)**	5 (20 %)
It is comfortable to wear.	0 (0 %)	1 (4 %)	5 (20 %)	**12 (48 %)**	7 (28 %)
The display is satisfactory.	0 (0 %)	2 (8 %)	5 (20 %)	8 (32 %)	**10 (40 %)**
The sound is satisfactory.	0 (0 %)	1 (4 %)	8 (32 %)	**12 (48 %)**	4 (16 %)
Good responsiveness to commands.	0 (0 %)	1 (4 %)	5 (20 %)	**13 (52 %)**	6 (24 %)
Use on the construction site is very useful, welcome.	0 (0 %)	0 (0 %)	7 (28 %)	7 (28 %)	**11 (44 %)**

The majority (40%) of respondents found the use of the advanced device to be straightforward, easy, with no respondents completely disagreeing.

Regarding comfort, over half of the participants (48%) agreed that wearing the advanced device was comfortable, and 28% fully agreed.

A significant factor in device usability is satisfactory content display. Eight percent disagreed with the display quality, while 40% expressed complete agreement, indicating a prevailing positive view.

Concerning sound quality, 48% agreed that the device provided satisfactory sound, while only one person disagreed, emphasizing the importance of clear and loud audio on construction sites.

Evaluating responsiveness to commands, the vast majority (76%) agreed that the advanced device responded well to both voice and gesture commands.

The final statement, "The use of the advanced device on the construction site is very beneficial and welcome," received overwhelming agreement, with 72% fully supporting its usefulness on construction sites. Respondents generally praised the advanced device for user-friendliness, comfort, display quality, sound clarity, responsiveness, and unanimously recognized its substantial benefits for construction site use.

It should be borne in mind that the respondents had only used the device for a short period of time.

The most important and the thirteenth question was: What do the respondents consider to be the biggest advantage of using an advanced device on site compared to the traditional approach? The vast majority of respondents (17), as much as 68%, answered that better visualization is the biggest advantage when using an advanced device on a construction site compared to a traditional approach. 4 people felt that the biggest benefit was better collaboration, and 2 people chose faster construction as the answer. 1 person answered that higher accuracy is the biggest advantage, while 1 person identified it as lower cost. No one recognized greater safety as a sufficiently important factor, nor did they highlight other examples.

When asked whether they would like to use the advanced device they tested in their work, as many as 17 people out of 25 respondents expressed a desire to use the advanced device in their work. The remaining 8 people, which represents 32%, do not. It can be concluded that the advanced device left a good impression on the respondents and that they see sufficient advantages in its use.

The final open-ended question was: What is your opinion about the usefulness of an advanced device in an advanced approach in construction compared to a traditional approach? Respondents varied in their opinions on the utility of the advanced device. While some declined to respond, the majority viewed the device as highly beneficial for on-site visualization during construction, emphasizing its role in providing a clearer understanding of the project, facilitating control, and comparing the actual state with the planned one. Two respondents highlighted its usefulness in swiftly resolving issues on-site. Improved communication between clients and contractors emerged as a significant advantage, aiding those struggling with 3D visualization. One respondent favored the advanced approach, citing error reduction, cost savings, and increased profitability. However, concerns were raised about the limited presence of such devices in construction, undervaluing their potential. One respondent emphasized the device's usefulness only when all details in the model are precise; otherwise, it is deemed a waste of time. Ensuring adherence to plans and instructions was seen as crucial for successful implementation. Traditional approaches were criticized for deviations, causing delays, unforeseen costs, errors, and tensions among participants. Participants found it challenging to comment on the downsides of advanced technology due to limited experience, but highlighted high costs, potential discomfort during use, and the risk of damage as concerns. The unfamiliarity with advanced technology among participants raised questions about collaboration efficiency, potentially leading to conflicts and misinterpretations.

Result analysis

Visualization on construction sites brings numerous advantages, fostering better understanding of projects and facilitating coordinated workflow. The Trimble XR10 with HoloLens 2 proves invaluable in envisioning the final structure, understanding project elements, and determining necessary construction tasks. Its user-friendly interface and versatility contribute to its ease of adoption, with the Trimble Connect AR+MR application being central to the study. While highlighting the device's benefits, the text explores its applications, advantages, and its potential impact on the construction industry.

The advanced device offers several advantages, such as ease of use, good visualization, seamless integration of 3D BIM models into real environments, display of work sequences, improved communication, and quick access to data, and archives. The rising accessibility of such devices due to affordability and mass production signals a shift towards incorporating advanced technologies in construction, gradually replacing traditional methods.

The paper also discusses the intricacies of model placement using QR codes and acknowledges limitations, such as imprecise projections without QR codes. External factors, like weather conditions, impact the success of QR code applications, necessitating laminated codes for durability. Practical challenges include language barriers, as commands are predominantly in English, posing a hurdle for non-English-speaking construction workers.

The importance of sequences using the advanced device becomes evident for project supervisors, managers, and other participants. Creating sequences proves crucial for specific and intricate tasks, ensuring precision in the construction process. The ability to convey the work sequence aids in organizing diverse workgroups, clarifying task logistics, and addressing critical points. Adhering to established sequences promotes timeliness, well-organized workgroups, enhanced collaboration and better task comprehension.

However, challenges emerge, particularly related to the device's weight and discomfort during prolonged use. Issues arise in strong sunlight, impacting content visibility. The device's limited battery life, approximately 2 hours, poses a constraint but can be mitigated with additional batteries. Technical glitches, encountered during the application update process, temporarily interrupted the experiment, emphasizing the need for continuous software improvements and user support.

Despite initial skepticism and language barriers, worker feedback on the Trimble XR10 has been positive. The device's ability to bridge communication gaps between leaders and workers is seen as advantageous, with potential benefits outweighing drawbacks. The implementation of advanced technologies is seen as transformative, enhancing work conditions, reducing costs and expediting construction processes.

Conclusions

This paper explores the integration of BIM and XR for construction visualization, focusing on the significance of visualization, the BIM approach, XR technologies, and the device Trimble XR10 with HoloLens 2. An experiment conducted at a retirement home construction site, utilizing a customized 3D BIM model on the existing structure, provided valuable insights into the practicality of advanced technologies in construction. Despite some drawbacks, the Trimble XR10 showcased numerous advantages, emphasizing user-friendly operation, effective workflow and improved communication. The results highlighted positive responses from workers, acknowledging the benefits of advanced technology, particularly improved visualization using advanced devices over traditional approaches. The study suggests that investing in XR technologies yields significant benefits, improving productivity, communication, and project understanding in construction projects. Further research is recommended to analyze the use of XR devices under controlled laboratory conditions and to compare user experiences in ideal scenarios with actual building conditions. Validating investments in XR devices in combination with BIM approach would promote a deeper understanding of their impact on the construction industry.

Acknowledgments

The research was conducted in collaboration with the company GIC GRADNJE, d. o. o. and we extend our gratitude for providing the documentation and the 3D BIM model. We also express our gratitude to the survey respondents for their participation and for sharing their insights.

Abstract

This systematic literature review (SLR) examines the role of augmented reality (AR) and virtual reality (VR) in construction computing. It highlights how these immersive technologies enhance visualization, communication, and decision-making in construction in the whole life cycle. The review covers the evolution and applications of AR and VR in architectural modelling, building simulation, construction education, robotics, and site management. It also discussed the challenges and future directions of these technologies in construction computing, finding the bridge between technological advancements and practical application. The findings offer strategic recommendations for developing immersive technologies in building computing, aiming for a smarter, more efficient construction future.

Introduction

The historical trajectory of augmented reality (AR) and virtual reality (VR) in the realm of construction computing is a narrative of progressive integration and innovative breakthroughs. Mixed Reality (MR) is of increasing interest within technology but is not yet used widely. Hence, this study is not going to be concerned about MR or other immature immersive technology. Tracing back to the late 20th century, the inception of AR and VR technologies was primarily driven by the entertainment and military sectors (Lenoir, 2000; Lele, 2013). However, their potential for transforming the architectural and construction industries was quickly recognized (Prabhakaran, Mahamadu and Mahdjoubi, 2022; Safikhani et al., 2022). The progression from simple wireframe models to fully immersive simulations marks a period of rapid development in these technologies, reflecting a trajectory from nascent experimentation to sophisticated application.

As immersive technologies entered the building sector, they brought forth unprecedented tools for visualization and interaction. The application categories of immersive technology within construction have diversified over time. Initially, AR was utilised to overlay digital information on physical environments, enhancing the understanding of complex structures (Li, Nee and Ong, 2017). VR, on the other hand, allows for complete immersion within virtual constructs, providing a platform for thorough review and planning without the constraints of physical models (Seth, Vance and Oliver, 2011). In contemporary practice, these technologies have found various applications. For example, in architectural modelling, AR and VR facilitate the exploration of design alternatives in real time, allowing architects and clients to visualize changes instantly (Delgado et al., 2020; Shouman, Othman and Marzouk, 2022). In building simulation, they enable the assessment of building performance under different conditions, aiding in the optimization of energy efficiency and structural integrity (Niu, Pan and Zhao, 2016). The use of AR in construction education has revolutionized the learning experience, providing interactive and engaging training environments that surpass traditional classroom settings (Sepasgozar, 2022). On construction sites, VR has been instrumental in safety training, providing workers with a risk-free environment to practice and understand complex scenarios (Chan, 2012). Furthermore, AR has been utilized for on-site construction management, where it aids in precise installations and maintenance through visual guidance and information overlay (Li et al., 2018).

Despite these advancements, the application of AR and VR technologies in construction computing is not without challenges (White, Schmidt and Golparvar-Fard, 2014; Wang *et al.*, 2018). The industry faces a disconnect between the evolving capabilities of these technologies and their practical implementation. Therefore, this study will systematically investigate and analyse the various issues encountered by immersive technology applications within the field of construction computing referring to the application of computational technologies and methods in the construction industry to improve the design, planning, management, and operation of construction projects., summarizing and identifying their underlying causes.

The primary objective of this study is to critically evaluate the impact of AR and VR on building construction. The nearest related literature review study was finished in 2018 and only focuses on construction safety. This study will gather the latest technology and the literature review focus on technological innovation and new applications. It will scrutinize how these immersive technologies are currently being harnessed to enhance the efficiency, accuracy, and safety of construction projects. The research will systematically categorize the different applications of AR and VR in construction, focusing on their roles in project planning, on-site execution, and post-construction evaluation. The study will delve into the technological nuances of these applications, assessing their operational merits and identifying the factors that limit their wider adoption and effectiveness in the field.

By doing so, the paper aims to unearth the root causes of the disparity between the potential of these technologies and their actual application outcomes. It seeks to provide insights that could drive the removal of barriers to adoption and optimize the application of AR and VR in the construction industry.

Methodology

This study endeavours to execute a balanced and analytical examination of the literature pertaining to the application of AR and VR technologies in construction computing. To fulfil this aim, the research adopts a methodical approach that combines both systematic (PRISMA) and narrative literature review techniques. Originating in medical science, the systematic review method strives for a comprehensive collation of information from diverse sources, ensuring transparency and rigor (Tranfield, Denyer and Smart, 2003). Renowned for its meticulousness and replicability, this method is instrumental in guiding decision-making (Moher *et al.*, 2009; Okoli and Schabram, 2010). The narrative review will concentrate on explicating and discussing various dimensions of immersive technology in construction, encapsulating advanced knowledge in the sector, including technological innovations, operational methods, and strategic directives.

((TITLE-ABS-KEY ("Immersive Technologies") OR TITLE-ABS-KEY ("Augmented Reality") OR TITLE-ABS-KEY ("Virtual Reality")) AND TITLE-ABS-KEY ("Computing") AND TITLE-ABS-KEY ("Construction")) AND ((TITLE-ABS-KEY ("Architectural design") OR TITLE-ABS-KEY ("Simulation") OR TITLE-ABS-KEY ("Construction management")) OR (TITLE-ABS-KEY ("Devices") OR TITLE-ABS-KEY ("Facilities")) OR (TITLE-ABS-KEY ("Trend") OR TITLE-ABS-KEY ("Challenge"))) AND (LIMIT-TO (SRCTYPE , "j")) AND (LIMIT-TO (PUBSTAGE , "final")) AND (LIMIT-TO (DOCTYPE , "ar")) AND (LIMIT-TO (PUBYEAR , 2019) OR LIMIT-TO (PUBYEAR , 2020) OR LIMIT-TO (PUBYEAR , 2021) OR LIMIT-TO (PUBYEAR , 2022) OR LIMIT-TO (PUBYEAR , 2023)) AND (LIMIT-TO (LANGUAGE , "English"))

Figure 1: Variable search string

Data collection

In the research, the initial phase was to delineate the pertinent literature's boundaries, thus informing the refinement of our search parameters. The current phase meticulously maintains core search terms while encompassing a spectrum of conceptual terms related to immersive technologies within construction computing. This amalgamation of terms (immersive technologies, augmented reality, virtual reality) with pertinent domains (architectural design, simulation, construction management) and challenges yields a search query both exhaustive and nuanced. Reflecting the evolution of construction computing since the early 2010s and acknowledging publication lags, our temporal search parameters span from 2019 to 2023 to ensure the inclusion of the most recent and relevant findings. Additionally, to ensure the retrieved literature's relevance and scholarly impact, we filtered for articles published in English and excluded early access reviews, focusing on articles with empirical evidence that illuminate the application challenges of AR and VR in architectural computing.

In the initial phase of our literature review, the search strategy outlined in the mind map identified 66 articles post-consolidation from both Scopus and Web of Science databases. This process parallels the systematic methodologies observed in other architectural computing studies (e.g., Smith and Jones, 2019; Doe et al., 2020). The following multi-stage evaluation was implemented:

i. We excluded 7 duplicates, refining the selection to 59 articles.
ii. Accessibility checks further narrowed the pool, with 27 articles excluded due to restricted access, insufficient impact factor, or lack of an abstract, leaving 32.
iii. Relevance to the topic was the next criterion, with 8 articles deemed of low relevance and 24 classified as highly relevant.
iv. The final assortment comprised articles that not only aligned closely with the thematic core of immersive technologies in construction but also promised significant contributions to the field, ensuring a robust foundation for our analysis.

In the final

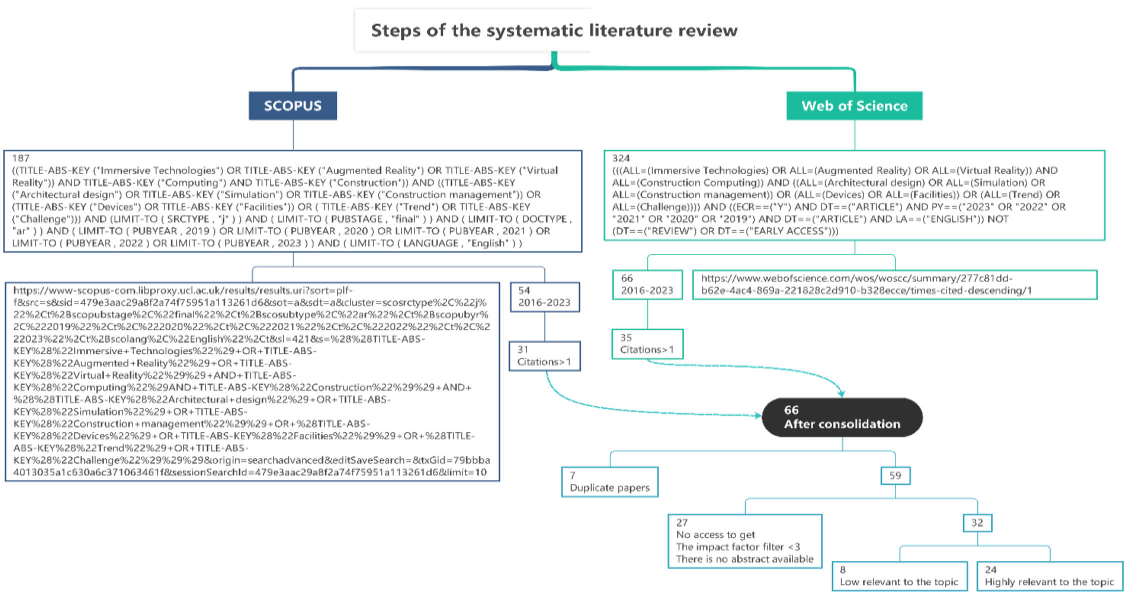

Figure 2: Steps of the systematic literature review

selection phase, a dual review approach, integrating both systematic and narrative methodologies, was employed. Through this mode, 24 papers of high relevance were meticulously identified, resonating with the central inquiry ‘What are the challenges and deep-seated reasons for the issues arising from the application of immersive technologies in construction computing?’ This thorough and discerning process entailed an in-depth examination and critical assessment of the literature, ensuring the inclusion of only the most significant studies that would contribute to the analysis and discussion of the identified challenges in the field.

Data analysis

To delineate the current landscape and progression within the field of immersive technologies in construction computing, this study conducted a scient metric analysis using VOSviewer. The initial visualization, presented in Figure 3, illustrates the clustering of keywords into three main groups. The first cluster is centred on the educational aspect, indicated by terms like 'student', 'training', and 'behaviour', suggesting a focus on the role of immersive technologies in learning and skill development. The second cluster revolves around the construction industry with 'construction site' and 'industry' as prominent nodes, pointing to discussions on the application of technologies in construction settings. The third cluster relates to the technological framework, including 'AR', 'information', and 'experiment', highlighting the emphasis on technology deployment and testing within the industry.

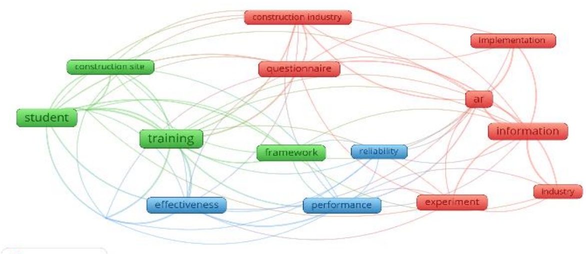

Figure 3: Co-occurrence of keywords in the literature

Figure 4 represents the temporal distribution of keyword occurrences, with yellower hues indicating more recent discussions. This shows that over time, there is an increased emphasis on the application and practical effects of certain technologies, with ‘implementation’, ‘construction site’ and ‘effectiveness’ being the latest topics to gain traction.

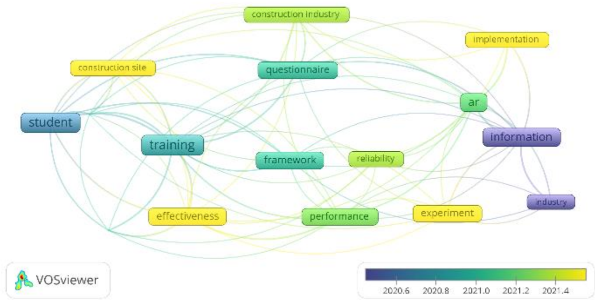

Figure 4: Timeline of keywords

Figure 5 focuses on the network of terms associated with 'immersive virtual reality'. This network shows connections to 'effectiveness', 'performance', and 'training', indicating that immersive virtual reality is primarily discussed in the context of its efficacy and performance in training scenarios within the construction sector.

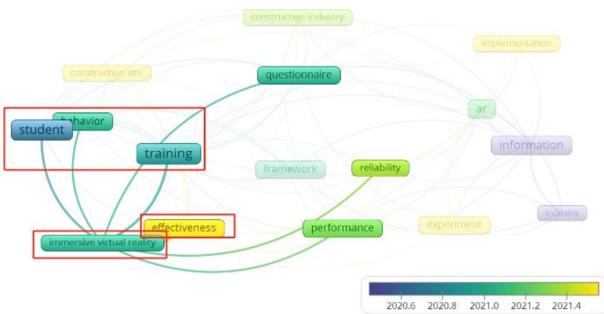

Figure 5: The main network of immersive virtual reality

Figure 6 depicts the relationships surrounding 'AR' technology. Here, 'AR' is linked to 'implementation', 'information', and 'experiment', suggesting that the current discourse is concerned with how AR is implemented in practice, the information processing capabilities of AR, and its experimental application in the field.

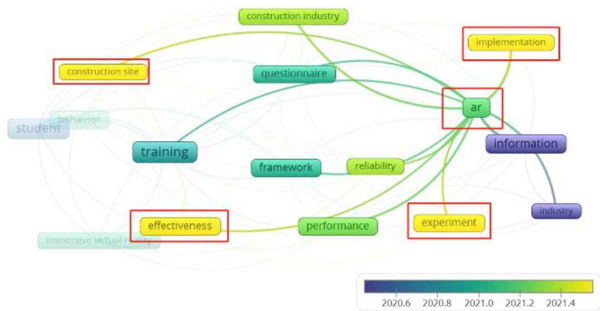

Figure 6: The main network of AR

Finally, Figure 7 reveals the density of keyword occurrences within the analysed papers, with the most frequently appearing terms encased in red. 'Student', 'training', 'AR', and 'information' appear as the most prominent terms, indicating these are central to the current research landscape within the selected body of literature.

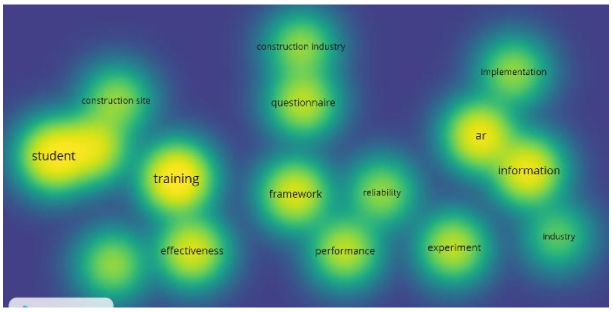

Figure 7: Heatmap of keywords

In conclusion, after analysing the key information of 24 articles, it is found that people are focused on the application of immersive virtual reality and AR technology in training and information dissemination. Density analysis highlights the centrality of educational applications and technology implementation as key areas of current research interest. Therefore, in the subsequent Narrative Literature Review, this study will focus on these contents.

Discussion and Result Analysis

The results of this systematic literature review illuminate the multifaceted roles that immersive technologies, specifically AR and VR play in the field of construction computing. The analysis, grounded in a review of 24 scholarly articles, reveals three pivotal areas: current developments, technological challenges, alongside future development shown in Table 1.

Table 1: Analysis result index table

Current Developments	Immersive technology applications	Education and Training	(Huang et al., 2020; Kim et al., 2020; Lucas, 2020; Sedlák et al., 2022; Sepasgozar, 2022)
		Auxiliary construction	(Sakib, Chaspari and Behzadan, 2021; Gath-Morad et al., 2022)
		Operation, Maintenance and Safety	(Maharjan et al., 2021; Raimbaud et al., 2021)
	Breakthrough cases	VR training to construction robots	(Huang, Zhu and Zou, 2023)
		VR remote control robot	(Wang et al., 2021)
Technological Challenges	Visual Challenges	360-degree panoramas have limited quality	(Ahn, Han and Al-Hussein, 2019; Eiris, Wen and Gheisari, 2022)
		High latency and slow rendering	(Hamzeh et al., 2019; Mutis and Ambekar, 2020; Zhou, Zhu and Du, 2020; Fu et al., 2023)
	Precision Challenge	Positioning accuracy	(Mutis and Ambekar, 2020)
		Location tracking accuracy	(Mutis and Ambekar, 2020)
		Image recognition and collection accuracy	(Wu et al., 2020; Zhou, Zhu and Du, 2020; Wang et al., 2022)
	Human experience	Lack of comfort, safety and reliability	(Maharjan et al., 2021; Raimbaud et al., 2021)
Future Developments	Technological Development	Optimization algorithms	(Zhou, Zhu and Du, 2020; Jahanshahloo and Ebrahimi, 2022; Zhang et al., 2023)
		Customer-specific mixed reality systems	(Wu et al., 2019)
		AR should be extended to other procedure	(Ahn, Han and Al-Hussein, 2019)
	Ecosystem Development	The government makes policy or compels it	(Shahzad et al., 2022; Arowoiya et al., 2023)
		Workers and operators involved in experiments	(Arowoiya et al., 2023)

Current Developments/Applications

1) Immersive technology applications

The adoption of VR and AR in the realm of education and training within the construction industry has been significant. Huang et al. (2020) and Kim et al. (2020) have demonstrated that VR can greatly enhance the training process by simulating realistic construction environments, allowing trainees to practice without the physical risks associated with construction sites. Lucas (2020) and Sedlák et al. (2022) further support this, noting that such immersive experiences lead to improved retention of information and a better grasp of complex structural designs. Moreover, Sepasgozar et al. (2022) emphasize the increased engagement and interaction that VR and AR technologies foster, which are essential for effective learning.

Meanwhile, in the auxiliary construction phase, the application of immersive technologies has been recognized for its contribution to preconstruction visualization and design verification. Sakib, Chaspari, and Behzadan (2021) discuss the utilization of AR for overlaying digital models on physical spaces, thus providing an immediate sense of scale and relation that 2D plans cannot. Gath-Morad et al. (2022) add to this by identifying how these technologies assist in identifying design conflicts before construction begins, potentially reducing costly errors and delays.

Moreover, addressing operation, maintenance, and safety, Maharjan et al. (2021) have found that AR applications improve maintenance tasks by enabling operators to visualize machinery components and operational data in real time. Raimbaud et al. (2021) highlight the impact of VR in safety training, where workers can be exposed to hazardous scenarios in a controlled virtual environment, thereby enhancing safety awareness without actual risk.

2) Breakthrough cases

The training of construction robots using VR is a significant advancement as well, as noted by Huang, Zhu, and Zou (2023). They provide insights into how robots can be programmed to perform complex tasks in a virtual setting before being deployed on-site, which could lead to increased precision and efficiency in construction activities. In addition, Wang et al. (2021) have introduced the concept of remotely controlling construction robots via VR, which allows operators to manipulate equipment from a distance. This application not only improves safety by reducing human presence on-site but also enhances the precision of tasks performed by the robots.

Technological challenges

1) Visual challenges

Visual fidelity is a significant concern in the deployment of immersive technologies. Studies by Ahn, Han and Al-Hussein (2019), Eiris, Wen and Gheisari (2022) emphasize that despite the advancements, 360-degree panoramas in VR still face limitations in quality, which can detract from the user experience and the intended realism. The visual challenges extend to the resolution and rendering speeds, as noted by Mutis and Ambékar (2020), where high latency and slow rendering can impact the effectiveness of training and operational simulations in VR environments.

2) Precision challenges

Precision in immersive environments is crucial, particularly in construction applications where spatial accuracy is paramount. Mutis and Ambékar (2020) discuss the challenges in positioning accuracy, where even minor discrepancies can lead to significant errors in the field. Similarly, location tracking accuracy is essential for AR applications where digital information must align precisely with physical elements. Wu et al. (2020), Zhou, Zhu and Du (2020), and Wang et al. (2022) highlight the need for improved image recognition and data collection accuracy to ensure that AR and VR systems can be reliably used for complex construction tasks.

3) Human experience challenges

Adoption of any new technology comes with the need to address human-centric concerns. Maharjan et al. (2021) and Raimbaud et al. (2021) have identified a lack of comfort, safety, and reliability as barriers to the widespread adoption of AR and VR in construction. The physical discomfort associated with prolonged use of headsets, the psychological unease some users feel in virtual environments, and the reliability of the systems in delivering consistent experiences are areas that require further research and development.

4) Other challenges

Eiris (2022) presents a challenging case where collaborative student behaviours did not directly lead to successful problem resolution, signifying that collaborative acts must be preceded by effective problem-solving actions. On a more positive note, Fu (2023) acknowledges data security challenges in the evolving metaverse but suggests that the advancement of blockchain and smart networking technologies holds promise for establishing a trustworthy and interactive digital environment. Wu's (2019) research offers a success story, indicating that despite a lack of expertise, students, as novices, can exhibit behaviour patterns akin to professionals and achieve comparable design review results through VR and MR models, showcasing the acceptability of these technologies in training. Furthermore, Huang (2020) documents the success of using VR to create a safe, cost-effective, and sustainable welding skills learning environment, which has been positively received by most students. These examples highlight the varying outcomes and acceptance of immersive technologies within educational settings.

Limitations of the study

This study establishes a profound understanding of the current research and practice regarding the application and challenges of immersive technologies in construction computing. However, the scope and methodology choices bring certain limitations. Firstly, although this paper systematically reviews literature from 2019 to 2023 to capture the latest trends, this time frame might have limited our consideration of earlier research outcomes, which are crucial for understanding the long-term development trajectory of immersive technologies. Secondly, the language limitation in the literature selection process (including only English literature) might have excluded significant studies in other languages that could offer different perspectives and insights.

Moreover, this study focuses primarily on AR and VR technologies and does not fully explore the potential of related technologies such as Mixed Reality (MR) and Extended Reality (XR), which are also showing increasing application prospects in the construction field. In terms of case analysis, despite efforts to select a diverse range of successful and unsuccessful cases, the quality and quantity of publicly available information might have not fully revealed the complexity and multidimensional factors behind these cases.

In discussing technological challenges, the paper focuses on visual challenges and accuracy issues, possibly without fully considering the organizational and management challenges encountered when implementing immersive technologies, such as difficulties in cross-departmental collaboration, differences in technology acceptance, and the impact on existing workflows. Furthermore, although the paper attempts to propose directions for future research and industry applications, these suggestions may be limited by the current research perspective and depth. Future work should further explore how to effectively address these challenges and achieve widespread application of immersive technologies in the construction industry.

Future developments

1) Technological Development

Future forecasts suggest an emphasis on the development of sophisticated optimization algorithms. Zhou, Zhu, and Du (2020), Jahanshahloo and Ebrahimi (2022), and Zhang et al. (2023) indicated the potential for these algorithms to enhance the performance of AR and VR applications in construction. Such advancements are anticipated to streamline data processing, improve rendering times, and provide more accurate simulations, thereby increasing the reliability and effectiveness of immersive technologies.

Furthermore, Wu et al. (2019) envision the customization of mixed reality systems to meet specific client needs. These systems are expected to integrate seamlessly with individual construction projects, providing tailored solutions that align with the unique requirements and challenges of each project. The focus will likely be on creating adaptive systems that can cater to varying scales and complexities of construction tasks.

In addition, the scope of AR is expected to broaden, as noted by Ahn, Han, and Al-Hussein (2019), to encompass other construction-related procedures beyond the current applications. This could include tasks like real-time project monitoring, on-site worker assistance, and integration with Internet of Things (IoT) devices to provide a holistic and interactive construction management ecosystem.

2) Ecosystem Development

Shahzad et al. (2022) and Arowoiya et al. (2023) suggest that government policy and regulatory frameworks will likely play a critical role in the adoption of immersive technologies in construction. The development of standards and policies can encourage the use of AR and VR, ensure data privacy, and promote safety standards in their application. Besides, the future development of the immersive technology ecosystem in construction is also predicted to involve greater participation from the workforce. Arowoiya et al. (2023) emphasize the importance of engaging construction workers and operators in the development and testing of AR and VR systems. This inclusion is crucial to ensure that the ecosystem developed are user-friendly, meet the practical needs of the users, and are effectively adopted in construction practices.

Conclusions

This study highlights the transformative potential of AR and VR in construction computing, alongside the need for targeted advancements and strategic implementations for their full realization. These immersive technologies promise to revolutionize construction through various applications, offering unparalleled opportunities to enhance training, safety, operational efficiency, and design verification by simulating realistic environments and integrating digital models into physical spaces. Addressing the challenges identified requires a multifaceted approach in future research. Key strategies include establishing a cross-disciplinary framework for collaboration across fields like computer science, architectural design, and human-computer interaction to improve user experience and technology integration. Additionally, developing quantitative evaluation models is crucial for assessing immersive technologies' impact on construction projects, paving the way for their broader adoption.

Understanding the construction industry's technology acceptance and adaptability is vital, with focus areas including training needs, interface design, and perceived utility to foster user-friendly applications. Research should also explore interoperability solutions between AR/VR and digital tools like BIM, cloud computing, and IoT to enhance data integration and project management. For industry implementation, creating industry standards and policies in collaboration with associations and government bodies is essential for the regulated use of immersive technologies. Public-private partnerships and professional training programs are also pivotal in promoting AR and VR's widespread application in construction.

In conclusion, realizing the full potential of AR and VR in transforming construction computing requires overcoming technological and human-centric hurdles. Future efforts should concentrate on tailored solutions for bridging theoretical potential with practical application, including cross-disciplinary collaboration, technology acceptance studies, and advanced interoperability solutions. Simultaneously, supportive policies, partnerships, and training programs will facilitate immersive technologies' adoption, significantly impacting the construction industry.

EVALUATING MULTIUSER AUGMENTED REALITY FOR 4D CONSTRUCTION PLAN REVIEW

Saleh Alghamdi[1,2], John Messner[1], and Robert Leicht[1]
[1]The Pennsylvania State University, University Park, USA
[2]King Fahd University of Petroleum and Minerals, Dhahran, Saudi Arabia

Abstract

Construction plan review meetings benefit from visualizing 4D construction models using various media such as Immersive Technologies (ImT). However, ImT, such as Augmented Reality (AR), have not been thoroughly investigated for their effects on collaborative reviews. This paper aims to evaluate the effect of using a developed 4D Multiuser AR (4DMAR) application on task performance using a comparative study against a screen-based environment. A questionnaire and observational data were used to measure the participants' experience and preferences. Sixty-two students found the interaction in both environments easy but perceived 4DMAR as more interactive and suitable for collaborative plan reviews.

Introduction

Construction projects are highly complex and dynamic and involve many interdependencies between activities (Sterman, 1992). In addition, almost every construction project is unique in design, materials, construction methods, and the surrounding environment. Therefore, many challenges exist during the construction process that take time to identify in the design process. For instance, planning the site logistics layout, especially in congested areas, can be difficult without simulating the construction process.

Incorporating visualization techniques to enhance the planning process for a construction project can be highly beneficial. As an example, Guo et al. (2017) found that visualization can enhance the identification of safety hazards before and during the construction phases of a project. It also increases our efficiency in dealing with complicated issues requiring high cognitive levels (Johnson, 1998). The most appropriate visualization method will depend on several factors, including the scope and depth of the project, the experience levels of the team members involved in the planning process, and the available resources. By carefully considering the unique needs of each project, it is possible to identify the most effective visualization methods for enhancing planning and achieving the required results.

While traditional 2D drawings and 3D models can provide a valuable visual representation of aspects of the construction process, they may not always be the most efficient way to navigate the sequence of construction activities. Adding time as another dimension in a 4D model enables the visualization of the construction sequence. Visualizing the construction sequence can provide insights into unforeseen problems and the site layout, considering the transportation cost (Bortolini et al., 2019). Hartmann & Fischer (2007) provided a case study where 3D/4D models support constructability reviews and convey general information to all stakeholders. The models were used to convey the details of the construction plan to all stakeholders, even those who are not engineers, and it is one of the examples of using 4D models in the construction industry. 4D modeling can also yield better coordination between disciplines (Staub-French & Khanzode, 2007).

Immersion affects how people interact with the environment, including increased attention (Silva et al., 2017). One of the most promising options to improve construction project planning is to use ImT, such as AR (Davila Delgado et al., 2020). This can be especially valuable in complex construction projects with many stakeholders with diverse perspectives and interests. Using AR can improve experts understanding of the design and construction of a project (Meža et al., 2015). Virtual Reality (VR) can visualize 4D construction plans and support constructability analyses (Haymaker & Fischer, 2001; Al-Adhami et al., 2018).

Immersive technologies offer new possibilities for multi-user interactive visualization to review construction plans. However, collaborative reviews in AR have not been thoroughly studied. This study aims to assess the impact of immersive, multi-user AR on task performance when reviewing 4D construction plans. To accomplish this, several objectives were pursued. First, a multi-user AR solution, termed 4DMAR, was developed to visualize 4D models through head-mounted AR headsets. Subsequently, a quasi-experiment was conducted to evaluate the effectiveness of the 4DMAR solution in facilitating multi-user construction plan reviews. This experiment involved conducting interactive multi-user sessions and employing various data collection methods. The study involved 62 participants who completed a questionnaire to collect perceptual data on their overall experience and preferences along with the collected observational data.

Related Works

Several papers that have presented an AR construction application were identified (see Table 1). In general, two different types of AR displays were used, including screen-based, such as using the camera on a tablet PC and projecting augmented information on the screen, and head-mounted, where augmented content was directly placed in the user's view of the space. Very few examples of head-mounted AR were identified in the literature.

Lin et al. (2020) developed a prototype for using screen-based AR and 4D modeling to enhance the operations of a tower crane. The paper did not provide an assessment of the usability of this prototype. However, it demonstrated how AR could translate 4D model information into showing the lifting path sequence. Lin et al. (2019) developed another prototype for construction progress monitoring using AR to show the construction sequence.

Another early study demonstrated a detailed approach to visualizing construction activities using AR and GPS (Behzadan & Kamat, 2013). This research provided a technical evaluation and demonstration of how a platform could be developed to visualize objects in their future physical location. The paper showed the possibility of a multiuser interactive AR construction model. Wang et al. (2014) used a 4D AR model to discuss construction issues through multiple stakeholders in a collaborative environment. The model helped visualize a natural gas plant's complex construction. The presented model was interactive and provided insights into safety issues. One of the comparative examples is the one provided by Kim et al. (2012). They provided an interactive multiuser and immersive AR tool to visualize equipment operation on the construction site. The tool provides multiple pieces of equipment to visualize different scenarios. Lin et al. (2015) provided an example of using screen AR for site plan review in a multiuser environment. The paper evaluates the use of AR using the time spent reviewing the plan. Also, it provides some perceptual feedback using a user-experience questionnaire.

Different evaluation approaches have been used to consider the impact of using AR/VR in design reviews. Most studies used questionnaires focusing on the user experience regarding comfort or how they enjoyed the experience. For example, Amrollahibuki (2019) used a questionnaire to evaluate the user's overall experience. One of the assessment methods that can be used is to compare the learning outcomes between the use of immersive technologies and traditional environments. A similar example was provided by Wolfartsberger (2019), where added flaws to the design were used to evaluate the VR value. However, this application was specific to electric equipment (power units), and flaws were quantified based on the design elements being reviewed, such as ergonomic or design issues. In the construction context, this can be difficult to quantify and categorize due to the lack of design standardization, which makes this method difficult to apply. Wang et al. (2022) used a weighted evaluation metric to control an assembly process's AR experience. For example, the presented metric can evaluate how the users felt about manipulating the objects.

Two gaps were identified throughout the literature. First, many previous examples provided concepts or prototypes of using AR for construction planning; however, these were often confined to proof-of-concept implementations due to technological limitations of early AR devices like poor computing performance, inaccurate synchronized alignment of objects, and lack of multi-user capabilities. With recent advancements, building fully functional multi-user AR environments is viable. These technologies include advanced alignment methods that use image recognition and the increased performance of AR/VR headsets to handle larger amounts of information. Second, most previous examples were limited to feedback about user experience, with limited applications of an objective evaluation. Evaluating the methods is essential to consider this technology construction planning. Therefore, a comprehensive example of using AR as a review environment for collaborative work was evaluated in this experiment in the context of construction planning.

Developing A 4D Multi-User Augmented Reality (4DMAR) Visualization System

The 4D Multiuser Augmented Reality (4DMAR) system was developed following the framework in Table 2. Some elements in the framework, such as implementing

Autodesk Navisworks® and Autodesk 3ds Max®, are adopted from Boton (2018).

The primary use case was to enable multi-user, real-time visualization and interaction with 4D models in an augmented reality context. Key functional requirements included multi-user synchronization of the 4D model state, navigation of the model sequence using a time slider, and physical exploration of the model. The system architecture centered around utilizing the Autodesk Navisworks® platform for 4D building modeling capabilities, the Unity game engine for multiuser networking and augmented reality functionalities, and the Meta Quest Pro headsets as the AR delivery devices. Autodesk Navisworks® was selected for its robust 4D modeling toolset and integration with common BIM authoring tools. Unity provided a framework for spatial computing applications along with its multi-platform deployability. The Meta headsets offered a powerful option for an AR multiuser experience using the passthrough functionalities.

The system development started with creating the 4D model using Autodesk Navisworks®. Next, the model geometry was optimized using Autodesk 3ds Max® to reduce the polygon count. The next three steps were performed to develop the interaction in the Unity Realtime Development Platform, and then the app was deployed to the Meta Quest Pro.

Table 2 AR Experience Development Process

Steps	Resources	Description
1. Build the 4D model	• Autodesk Navisworks®	*Autodesk Navisworks® was used to build the 4D model.*
2. Optimize the 3D models	• Autodesk 3ds Max®	*The geometry of the 3D models was optimized for enhanced performance in the AR view.*
3. Customize the AR environment	• Unity Realtime Development Platform Oculus Package Manager	*The AR experience was enabled using the passthrough feature. The alignment of the model for multiuser was developed using a Shared Spatial Anchor (SSA)*
4. Create interactivity features	• Unity Realtime Development Platform • Oculus Package Manager	*Interaction features and User Interface (UI) were developed using Unity and Oculus UI.*
5. Build the multiuser platform	• Unity Realtime Development Platform Photon Unity Networking	*Photon Unity Networking was used to create rooms for multi-users.*
6. Deploy the app	• Meta Quest Pro	*The app was deployed on multiple headsets.*

A 4D model of a real constructed project with construction additional flaws added was developed. The purpose of adding flaws was to enable conversation elements and determine whether those flaws were noticed and in which review environment. The building used for this activity is a service and office building. The building consists of three floors and a basement. Only the structural and architectural models were used in the 4D model. The excavation tasks were included, and some exterior scaffolding for the masonry facade was added. Fifty-seven activities were represented in the 4D model. Figure 1 illustrates four major stages of the project, from excavation to completion. The first image on the top left shows the excavation activities of the basement and the footings. The top right image illustrates the finished basement, some steel erection activities, and the start of one concrete floor activities. The bottom left image shows the façade activities with the scaffolding highlighted in yellow, and the last image shows the completed project.

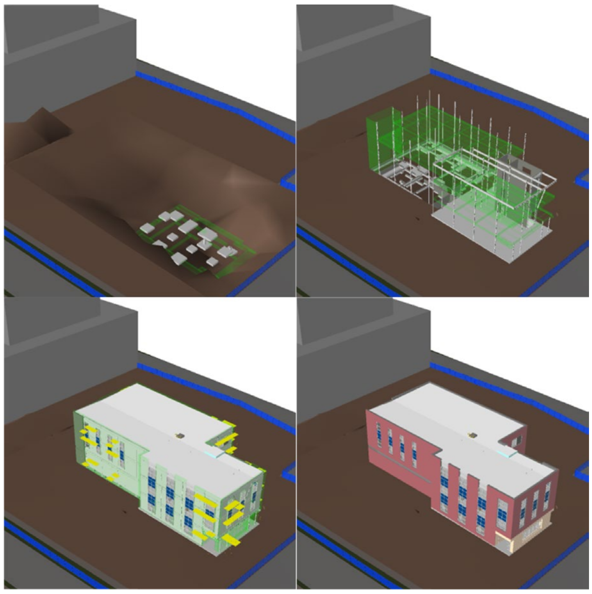

Figure 1: 4D Model Major Stages

The 3D geometry of the model was optimized to increase the system's performance by reducing the number of polygons. Reducing the number of polygons in a scene can increase the Frames Per Second (FPS) for displaying content in the AR head-mounted display. The Meta Quest Pro headsets perform better within a certain number of triangle counts or polygons, which are around 750k-1m triangles, to allow acceptable FPS as recommended by Oculus (2022). Oculus suggests that a minimum of 72 FPS should be targeted for optimal content viewing. Therefore, the model was optimized to increase the system's performance by reducing the number of polygons using tools incorporated into Autodesk 3ds Max®. However, this does cause quality reductions in the model for visualization, in which some elements lost some features like missing or reduced quality of a geometry. Because the model size was small when viewed in the physical environment, this issue was insignificant and did not affect the visualization of the building elements.

Customizing the environment was performed by adjusting the Unity Realtime Development Platform settings making it compatible with the Meta Quest Pro. The AR experience was enabled by using the passthrough video feature of the display. The alignment of the model for multiuser was developed using a Shared Spatial Anchor (SSA). Other alignment methods were considered, such as manual alignment using the controller. However, SSA provides a fast and relatively accurate geospatial positioning. The main interaction features added to the system were time navigation using a slider and moving the model using pinching by the controller side button. The slider was linked to an animation file that contains the construction schedule. However, using the animation file adds a limitation if there are future schedule changes, which should be addressed in the future development of the 4DMAR. The collaborative environment was built using the Photon Unity Networking Platform. The platform enables multiple users to enter the same rooms and share the same synchronized 4D model. The 4DMAR was tested on three different headsets simultaneously, two Meta Quest Pros and one Meta Quest 2, and it performed adequately. Figure 2 shows the built application of the AR review environment.

Figure 2: Examples of Users in the 4DMAR Application, each looking at a synchronized model instance

Assessment of the 4DMAR

To assess the performance of the 4DMAR, a quasi-experiment was performed. The assessment started with designing an experiment to reflect the assessment approach and a questionnaire to measure the participant's perception of the experience. Three pilot tests were performed to adjust and refine the experiment design.

The current practice used for reviewing 4D construction models in the industry is typically using a monitor(s) or a projector(s), referred to as a screen-based method in this study. Therefore, this research compared the 4DMAR as a review environment to the screen-based review, providing a shared resource in both options, see Figure 3. This led to the question: Can 4DMAR provide a suitable environment for reviewing 4D construction plans compared to screen-based reviews?

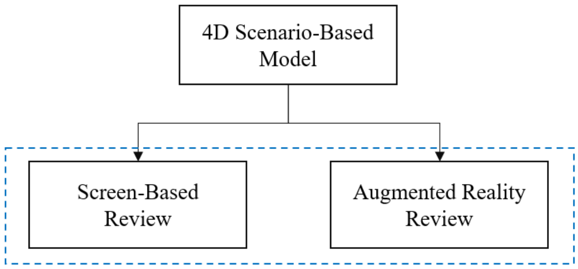

Figure 3: Evaluation Approach

The ability to review the 4D models was performed on two platforms: 1) the screen-based (SB) using Autodesk Navisworks® and 2) AR using 4DMAR. The laptop screen was rear-projected on a 6'x8' screen to ensure an appropriate view for a pair of participants. Similar interaction features, timeliner, and navigation were used in both environments. Also, to maintain the consistency of interactions between the two environments, the toolbar of Autodesk Navisworks® was hidden, and only the Timeliner was enabled in the screen-based 4D model review.

An experiment path was designed to test both environments, as seen in Figure 4. Since this is a multiuser activity, two participants performed each experiment. This was a deliberate choice to create a manageable multiuser environment while minimizing technological and data collection complexities that could arise with larger groups. To test whether the order of the experiment would affect the overall preference, another path was added, switching both environments, and it was annotated as path B. After each review session, a questionnaire was answered by both participants separately.

Each path started with a script that introduced the purpose of 4D modeling and what kind of flaws are usually found in a 4D model. It also introduced the design of the building being reviewed and how to interact with both environments. However, the script did not ask the participants to complete a specific task while reviewing the model and left the review open for participants based on the mentioned flaws.

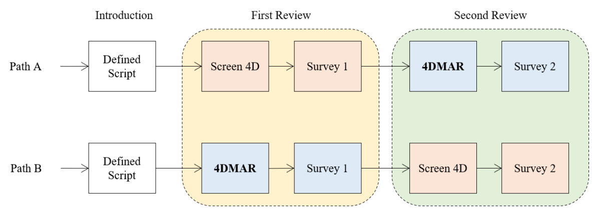

Figure 4: Experiment Paths

A questionnaire was designed to collect perceptual data. The questionnaire was answered individually after each review environment to address the second research question of whether the order of using the AR would affect the preference. The questionnaire was designed to test three factors: 1) overall experience, 2) interaction experience, and 3) overall preference between the two environments. Both usability and interactivity questions were rated on a 6-point Likert scale since participants will answer this for both environments and to make the comparison more distinctive. However, the overall preference includes both environments in the same questions, and a no-preference choice was added to reduce bias. More details are provided in Table 3.

Table 3: Questionnaire Design

Collected data	**Survey** 1	2	**Description**	**Question type**
Background information	✓		*Collected information includes sex at birth, industry experience, AR/VR experience, and Autodesk Navisworks® Experience. Collected as a subpart of survey 1 to minimize the number of surveys.*	*Open-ended questions and multiple choice*
Overall experience	✓	✓	*The rating included comfort, familiarity, enjoyment, ability to find flaws and opportunities, and need for technical support.*	*Likert scale Strongly agree – Strongly disagree.*
Interactivity	✓	✓	*Rating the interactivity experience of the interactive features, time navigation, model exploration, and ability to interact with a teammate.*	*Likert scale Easy – Hard*
Overall preference		✓	*The last part of Survey 2 asked about the overall preference*	*Likert scale AR – no preference (mid) – Screen-Based*

Figure 5 shows the two review environments' physical spaces. The blue boundary represents the guardian set for all headsets. During pilot testing, system functionality was assessed, along with clarity and adequacy of the questionnaire and the experiment flow. The pilot was performed on the apparatus of the experiment and how the flow of the other experiment was maintained.

Results and Discussion

Questionnaire Results

Sixty-two participants were involved in this experiment; 16 groups followed Path A, while 15 groups followed Path B. Consent was obtained from all experiment participants. Each group had two participants. The participants included 23 female and 39 male participants.

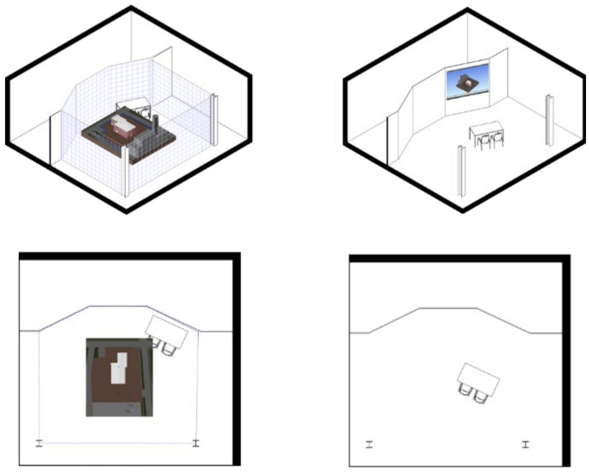

Figure 5: Review Environments Physical Space (left is 4DMAR and right is screen-based)

Forty-seven (76%) participants have had an internship experience in the construction industry. Most participants (82%) had limited experience using Autodesk Navisworks®, having used the software once or twice. In addition, most participants (71%) have experienced AR/VR headsets before, but a majority only experienced them once or twice.

Six questions were answered for both the SB and AR reviews to evaluate the user's overall experience with the review. All responses slightly favor AR as a review environment for the overall experience (see Figure 6).

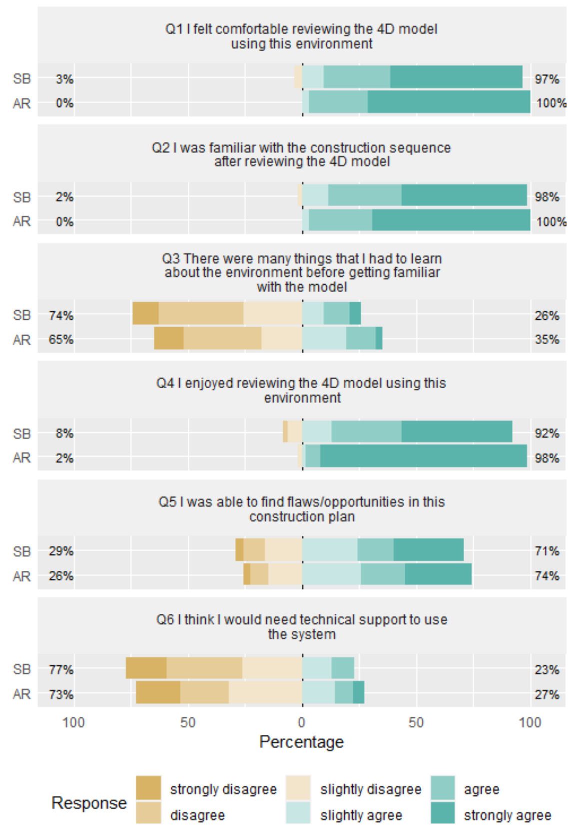

Figure 6: Overall Experience Response, Screen-Based (SB) top bar vs Augmented Reality (AR) bottom bar

Only one result showed a majority preferring AR: question 4, in which most participants strongly felt they enjoyed the AR reviews.

Three questions were used to rate the interactivity features in both environments. Similarly, the overall response slightly favors AR. Participants typically felt that it was relatively easy to interact with both environments. However, the questions were particular to the shared interaction features. See Figure 7 for a graphical representation of the Likert scale.

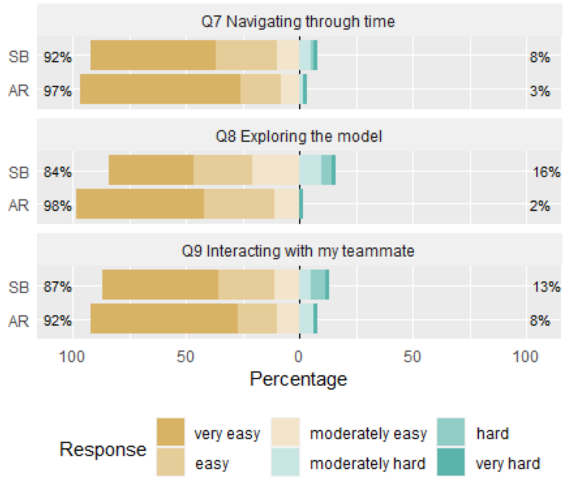

Figure 7: Interaction Response, Screen-Based (SB) top bar vs Augmented Reality (AR) bottom bar

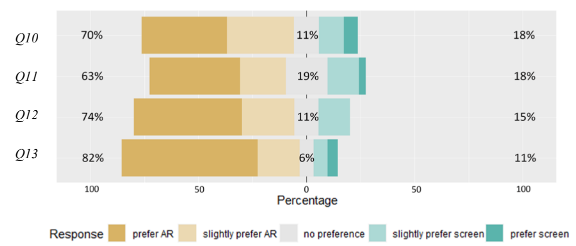
Lastly, each participant answered four questions on their overall technology preference after using both environments (see Figure 8). This data is further analyzed in the next section, considering the experimental path. Participants indicated they would prefer AR to be used in their next review in Q10. They perceive AR as having more potential to be used in the future, as answered in Q11. Also, in Q12, they perceive AR as giving them a stronger sense of depth, spatial awareness, and realism. In the last question, which helps answer the collaboration question, 63% of participants felt AR is more suitable for collaborative reviews, 19% had no preference, and 18% preferred screen-based reviews.



Q10: Next time, I will review the 4D model using:
Q11: In your opinion, which environment has more potential for construction plan reviews in the future?
Q12: Which environment provided a stronger sense of depth, spatial awareness, and overall realism for the models being presented?
Q13: Which environment do you think is better suited for collaborative work and group activities?

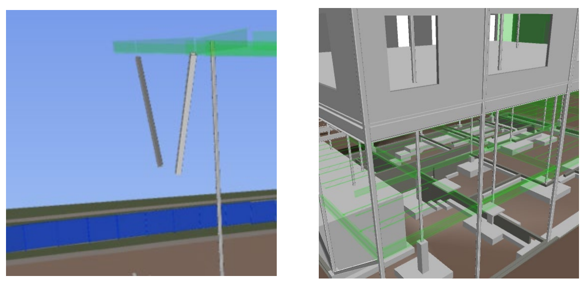
Figure 8: Preference Responses, Screen-Based (SB) vs. Augmented Reality (AR)

Observational Data

While performing the experiments, observational data were collected using video recordings. In addition, videos were analyzed to study participants' behavior using the two environments.

The experiment's script outlined the goal of the 4D modeling reviews, but there was no emphasis on participants recording any flaws or opportunities in the construction plan. This was intended to reduce the pressure on participants in a new environment regarding finding flaws. However, the performance of finding flaws was similar in both environments. Participants did not discuss any opportunities for improving the construction plan in either environment. It was also noticed that some participants assumed that the model was relatively accurate, although the experiment aimed to have participants critically review it. This might be related to their limited industry experience, lack of 4D modeling reviews, or lack of clear tasks.

Participants only identified flaws that were related to sequence activities. Only 13 of the 31 participating groups were able to identify sequencing flaws in the construction plan. These primarily focused on two sequencing issues that participants discussed, shown in Figure 9. The left (a) image shows a flaw in the sequence where two steel braces were installed ahead of the supporting members. The other flaw on the right (b) image shows the installation of the second floor before the start of the first-floor grade-beam install. The first flaw was found most frequently. The number of instances when participants found these flaws was similar for both 4DMAR and the screen-based. Seven groups identified at least one sequencing issue using the SB review, while six identified sequencing issues in the 4DMAR. When participants found a flaw in the environment, they usually did not discuss it again in the second environment. Whether there is an advantage to using the 4DMAR or SB cannot be demonstrated, but both can be used to identify flaws. Participants found no missing object flaws or flaws related to the model's construction methods in both environments. This was documented using the notes taken during the experiment when the participants discussed a sequencing issue. The participant sample consisted mainly of students with limited professional experience in construction planning and 4D modeling practices. Most

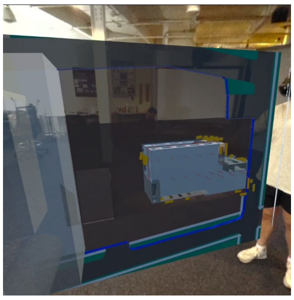


a) Steel structure sequence. b) Installation of the second-floor.

Figure 9: Sequencing Issues Found by Participants

had only used 4D authoring tools like Navisworks once or twice before. This lack of deep domain expertise may have caused many to assume the provided 4D model was largely accurate. While the experiment instructions mentioned that 4D models can reveal construction flaws, participants were not explicitly tasked to identify flaws or sequencing errors. Moving forward, we plan to enhance the experiment design by instructing participants to document the observed 4D model flaws or sequencing issues as part of the review exercise.

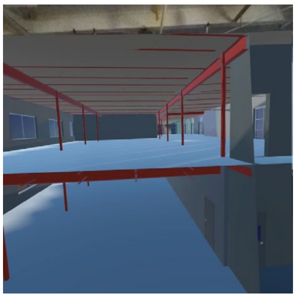
The 4DMAR has initiated different interactions compared to the screen-based. Figure 10 shows examples of the interaction methods unique to the 4DMAR, such as exploring the model's interior.



a) Rotating the model sideways.

b) Flipping the model upside down.

c) Going underneath the model.



d) Going inside the model.

Figure 10 Examples of the Interaction Methods

The primary research question investigated in this study was: Can 4DMAR provide a suitable environment for reviewing 4D construction plans compared to screen-based reviews? As indicated by the questionnaire results in Figure 8, 63% of participants felt AR was better suited for collaborative work and group activities compared to only 18% preferring the screen-based environment, while 19% had no preference. While task performance in identifying construction plan flaws was similar across both environments, the overall user preference for AR's interactive and immersive qualities supports its potential as an engaging platform. By counterbalancing the experiment paths (A and B), an order effect on preferences was not detected based on the collected data. This suggests that familiarity with the AR system did not significantly sway participants' judgments after experiencing both visualization methods.

Conclusions

Planning for construction sequencing is a complicated process that requires careful consideration. Visualizing the construction sequence is beneficial in determining possible challenges and opportunities in a construction plan, which heavily relies on the planners' experience. Collaborative environments that support model interaction and improved or novel visualization have previously shown benefits to the review process.

Participants generally preferred the 4DMAR regarding collaboration activities in the review quasi-experiments. Participants felt comfortable and enjoyed using the AR headsets and felt they could communicate with their teammates. The effect on task performance and collaboration was evaluated using an immersive, multi-user AR to review 4D construction models. Several objectives were achieved in this research. First, a multi-user, collaborative, immersive solution using AR, named 4DMAR, was developed for visualizing a 4D model. An assessment approach was designed and performed to evaluate the performance of the 4DMAR and show its potential to provide a collaborative environment. A comparative study was conducted to measure the performance of 4DMAR. 63% of participants felt AR was better suited for collaborative work and group activities than only 18% preferring the screen-based environment. By counterbalancing the experiment paths (A and B), an order effect on preferences was not detected based on the collected data.

While the results showed a user preference for AR for construction plan review, this has some limitations based on the participant pool and task definition. Future research should examine this technology with industry professionals to critically assess the potential benefits and challenges of adopting AR and address the limited industry experience of the participants to give a better judgment. Another key limitation identified was the low rate of participants detecting sequencing flaws in the 4D construction plan despite this being a primary use case. Incorporating explicit flaw identification tasks will be a critical focus for further developing the 4DMAR system. In addition, complex models that include different building systems should also be used to reflect more complicated challenges within extensive model reviews. Solutions such as performing more systems-selective task reviews to enable more value-based approaches can be explored. However, with the current limited computational power of AR headsets, it is very difficult to visualize large building information models without optimizing the meshes or using other proximity solutions.

A MIXED REALITY HUMAN ROBOT INTERACTION INTERFACE USING HAND TRACKING AND STEREO VISION FOR CONSTRUCTION APPLICATIONS

Damith Tennakoon[1], Mojgan Jadidi[1], and SeyedReza RazaviAlavi[2]
[1]York University, Toronto, Canada
[2]Northumbria University, New Castle, UK

Abstract

The modern day construction site is able to complete complex tasks using highly skilled on-site workers and robust machinery. On-site workers face severe physical injuries from unforeseen accidents due to construction site dynamics. This project proposes and implements a mixed reality human robot interaction system, utilizing stereo vision systems and hand tracking algorithms, to teleoperate a robot arm within a simulation. Results demonstrate enhanced depth and situational awareness in the robot workspace versus traditional teleoperation. This research allows operators to safely perform complex construction tasks remotely with a robot arm using a head-mounted display.

Introduction

The modern day construction site completes large-scale tasks by training on-site workers and utilizing heavy-duty machinery. However, success is not achieved with efficiency or safety as a major priority since construction work is prone to surpassing timelines and facing potential delays due to low productivity rates Davila Delgado et al. (2019). On-site workers are often subject to serious health consequences, that are frequently overlooked. Some of these hazards include exposure to high concentrations of particulate matter, workers colliding with heavy machinery, and falls off unsecured high altitude sites Yang et al. (2023); Castro-Lacouture (2009).

Various industries continue to adopt automation techniques, leveraging robotics solutions, to improve task efficiency, productivity, and product quality. For instance, the manufacturing industry utilizes robotics to automate assembly lines, with the advent of performing repetitive, hazardous, and time-constrained tasks with ease, to produce high volumes of products. Not only are robotics solutions very efficient, but are also highly competent with precision-seeking tasks as made evident by their applications within the medical field. The healthcare industry deploys robots to perform surgical procedures with the advent of providing minimally invasive procedures and higher precision than human surgeons. The advantages of uninterrupted work is highlighted by the application of robotics in agriculture where tasks including planting, harvesting, and monitoring crops are automated and carried out by multiple robots Campilho and Silva (2023). Huang and Sakurai (1990) concluded that the implementation of factory automation (FA) for well-established automotive companies, including Mitsubishi, Nissan, and Mazda, displayed a noticeable reduction in labor costs, an increase in vehicle quality, and increased flexibility for adapting tasks. An extensive study performed on the implications of introducing industrial robots into manufacturing firms showed increased worker safety; specifically, 1 standard deviation of an increase in robots resulted in a 4% reduction in physical job intensity and a 5% reduction in job worker disabilities Gihleb et al. (2022).

With the clear benefits that automation and robotics provide, many attempts have been made to integrate this technology into the construction industry. A study demonstrated the successful implementation of robots into performing construction tasks require the adaptation of robots to the unpredictable and dynamic nature of construction sites. This has been achieved in modern robotics in two ways: (1) pre-programming robots to handle many different scenarios and rigorously testing them prior to deployment and (2) by training robots, using sophisticated real-world datasets and machine learning techniques, for on-site applications. The fast-paced and dynamic construction environment prevents either of these requirements from being met; pre-programmed robots are not able to handle unforeseen tasks or changing tasks and quality training data for construction applications are limited Zhang et al. (2023). Mukherjee et al. (2022) suggests a more intuitive method to deploy robotics into the construction sector is to create a human-robot collaboration (HRC) system that integrates the on-site worker's experience with the advantages of autonomous robots, to increase task productivity and reduce labor shortage. Advent of such as system alleviates the need for dynamic robot programming and multiple task execution.

In order to perform any intricate task, a complex manipulator is required. Robot arms are used to interact with and manipulate objects within an environment via various teleoperation methods. Teleoperated robots are specially useful where the robot's physical target workspace is challenging or impossible to access. The most commonly used control interfaces for these instances are keyboards, joysticks, and portable touch screen devices. However, these traditional modes of teleoperation are ineffective as the control interfaces are not intuitive. One of the emerging solutions for this problem is the use of mixed reality technologies which facilitate full immersion into the robot's workspace, creating a more natural human-robot interaction (HRI) interface Meng et al. (2023); Wonsick and Padir (2020a). Mixed reality (MR) is a combination of augmented reality (AR) and virtual reality (VR) technologies. MR combines the real and virtual worlds to construct a hybrid environment where interactable 3D virtual models exist Aloqaily et al. (2023). The advent that mixed-reality HRI interfaces provides over traditional teloperational methods is the ability to view and interact with robots in 3D environments Wonsick and Padir (2020a). The ability to view in 3D is due to the emergent properties of 3D cameras and immersive head-mounted displays (HMDs). Compared to 2D video-based visualization, 3D real-time visualization coupled with HMDs has shown to improve localization, maneuverability, and control in robotics applications Wonsick and Padir (2020b).

In this paper, we introduce a novel HRI interface that leverages MR technology, state-of-art hand tracking methods, coupled with stereo vision systems to teleoperate a 4-DoF robot arm in an immersive first-person view (FPV) using a Meta Quest 2 HMD. By providing a mode to operate a robot arm using hand gestures from a safe distance to the manipulator, on-site construction workers can perform complex tasks, utilizing their experience, while taking advantage of the strength, precision, and deployabality of robots.

Related Works

Much research and development has accumulated over the past few years specifically on leveraging AR, VR, and MR technologies to effectively improve human-robot interaction and collaboration. Puljiz et al. (2019) proposes and implements an HRI interface to teleoperate an industrial grade robot arm utilizing the Microsoft HoloLens AR HMD. The approach presented utilizes the built-in spatial mapping of the HoloLens to identify the target robot arm, and its end effector. This is achieved by storing a previously known model of the robot arm and matching the known model with the detected mesh of the spatial mapping output. The known mesh and the HMD is localized with the detected robot arm, of the physical space, and hand detection techniques are used to translate the end effector. This interface enables the teleportation of a robot arm without the need for physical interaction with the manipulator.

Yim et al. (2022) emphasized the importance of full immersion into the robot workspace through means of stereo vision. They implement a method to teleoperate a 6-DoF robot arm by fix mounting an Intel RealSense stereo camera to the platform the robot arm is fixated on, with a view facing down and towards the end effector. The stereo images are streamed to a Meta Quest 2 VR HMD to replicate human vision. Hand held controllers are localized with the robot arm to manipulate its end effector. This HRI interface enables a robot to be controlled from a safe distance with human-like perception.

Chang et al. (2023) tackles on the ongoing challenge of effective robot workspace visualization and perception by their design of a 2D/3D multi-view teleoperated robot arm. Specifically, they have devised an approach to view a robot's workspace via an FPV real-time 3D point cloud (PCD) model, from a stereo vision camera mounted to the end effector of the manipulator, and a 2D view from a global RGB camera. This effectively enabled for the visualization of the direct workspace, via the PCD, as well as the global workspace, via the RGB camera. The developed MR interface enabled the user to switch between the two visual systems in their HMD, using a handheld controller, providing a comfortable teleoperation process.

Many other similar approaches have been proposed and implemented showcasing positive results towards achieving a natural HRI interface. Though, these HRI systems do not come without their own setbacks. With the implementation of the HoloLens AR approach by Puljiz et al. (2019), though the interface provides robot arm teleoperation without required physical interaction with the manipulator, it is constrained by the requirement of a physical operator needing to be present near the robot's workspace. This limits the control bandwidth as the operator needs to have a direct line-of-sight of the robot arm for teleoperation. In the case of the immersive stereo vision teleoperated robot arm developed by Yim et al. (2022), many safety issues arise when the user's view is obstructed by the robot arm itself or other objects, within the robot's workspace, due to the vision system being fixed mounted. Chang et al. (2023) is on the right track with their multi-view MR HRI interface, however, the cognition load required for the operator increases when frequently needing to switch between a 3D view and a fixed 2D view; the operator will need significant training to be comfortable localizing their coordinate system with the robot arm's coordinate frames, in the two views. Many lessons were taken away from all aforementioned approaches and has aided the development of the HRI interface discussed in this paper.

Methodology

Approach

The design of the HRI system that is being developed revolves around creating an immersive, hands-free, and safe interface to teleoperate a robot arm towards performing construction tasks. There are 4 main categories that are required to achieve this interface; (1) stereo vision system to replicate human-like perception; (2) immersive wearable technology to construct an immersive MR interface; (3) real-time hand-tracking algorithms for intuitive teleoperation; (4) tracking systems to provide real-time operator situational awareness.

The stereo vision system used for this project is the ZED Mini (ZEDM) stereo camera, developed by StereoLabs. Stereo vision is a visualization system that enables 3D point extraction of an environment, through images obtained via two cameras separated by a fixed distance. The general concept is founded on the basis of finding the disparity between the two images to extract the missing depth information, through means of geometry DANDIL and ÇEVİK (2019). The ZEDM camera replicates the human-eyes, enabling real-time depth perception, with extreme accuracy. The approach is to mount the ZEDM camera on top of the end effector of the 4-DoF (degrees of freedom) robot arm. The left and right videos will be streamed, in real-time, to the left and right displays of the Meta Quest 2 VR HMD. This enables the operator, wearing the HMD, to perceive the robot's point-of-view (POV) with human-like vision. Open source libraries utilize the 4 on-board cameras of the HMD, used for spatial mapping, to track the user's hands in real-time. The tracked hand models are superimposed to the FPV stereo view on the HMD. To provide full situational awareness, the ZEDM camera is mounted on a servo actuated two-axis gimbal that tracks the orientation of the HMD, in real-time. As the operator wearing the HMD looks around, the servo motors are actuated to map the HMDs look angles with the ZEDM camera. This will provide a natural one-to-one orientation system enabling full situational awareness of the robot's workspace. The ZEDM vision system has a noteworthy advantage of facilitating pass-through reality, allowing seamless integration of 3D virtual models into the real-time stereo images. This is a fundamental requirement for this HRI system since the robot arm will be controlled via an MR control sphere; in the FPV view of the HMD, a translucent spherical virtual object will be fixated onto the visualized end effector, using pass through reality. The operator will be able to place their hands into this tracking sphere towards the desired direction for the robot to move towards. Hand gestures, such as pinching and releasing two fingers together, will be detected to provide gripper controls.

This paper covers the development of the proposed architecture, in a simulated environment, and preliminary results from experiments conducted, comparing traditional teleoperation methods with the developed MR HRI interface, when performing simple tasks.

Simulation Environment Setup

The simulation environment chosen for this project was Unity Game Engine. Unity is a cross-platform game development engine that enables developers to build video games, simulations, and mixed reality applications, by utilizing 3D objects and scripting via the C# objected-oriented programming language Haas (2014). Unity was the ideal candidate for this simulation as it provides open-source libraries for AR, VR, and MR development. It is also built on the capable NVIDIA PhysX 3.4 physics engine, providing the ability to run real-time physics simulations.

The first step in designing a real-time simulated robot arm was selecting a 3D model that represented a real-world industrial grade robot arm, namely the manipulators developed by KUKA. The model used for this simulation was retrieved from the open-source 3D modelling website Sketchfab, by a developer named Yuki. The 3D model features a 4-DoF robot arm, in FBX format. In the Unity environment, the design underwent many modifications to organize the multi-component model into a structured hierarchical set of objects, where each rotating joint, connecting each of the links together, were aligned relative to a global coordinate system. To actuate the robot arm during run-time, a joint-space controller was scripted, enabling each joint to rotate to an input angle with a constant angular velocity. Although joint-space control for robot arm's are used in real-world scenarios, it is not representative of how robot arm's are often operated majority of the time. Rather, a target position vector, a 3D coordinate in space, is provided to the manipulator. The system then computes a set of ideal joint angles to achieve the desired end effector position. In robotics, this mathematical process is referred to as inverse kinematics, a key-part of robot trajectory planning. One of the challenges with inverse kinematics is for a given target end effector position, there may be infinite many solutions, leading to computation efficiency problems. Many open-source inverse kinematic solver libraries exist such as Ikpy library. Ikpy is a Python library that performs inverse kinematic solutions efficiently, given a kinematic chain, as a Unified Robotics Description Format (URDF) file, and a target position and orientation. A URDF file is a low level description file, written in the Extensible Markup Language (XML), which describes the geometry, mobility, and their corresponding relationships, of a robot. Utilizing the Unity 3D model, a URDF file was developed for the robot arm. To connect the Python inverse kinematic scripts to the Unity simulation environment, a Transmission Control Protocol/Internet Protocol (TCP/IP) server-client system was designed. TCP/IP is a data link protocol that enables the transmission & reception of messages, between devices, over an internet connection. A three-way handshake connection, between two devices, enables the host server to send packets of information to the client, where the client transmits a message back to the server, confirming data reception. TCPs error handling capability ensures reliable point-to-point communication, without data loss. Python TCP server scripts, integrating the inverse kinematic solvers, and the corresponding C# client scripts, were developed to establish a connection between the computing server and the simulation environment client. This simulation architecture is summarized in Figure 1 in which the 3D coordinates of a target object, in the Unity environment, is transmitted to the server which returns a set of joint angles to achieve the desired target position. The result is a 4-DoF robot arm that tracks and follows a target sphere object, in real-time. To further actualize the simulation, a prismatic gripper tool was designed, using the CAD modelling software Autodesk Fusion 360, and subsequently affixed to the end effector joint of the manipulator. To devise experiments relating to construction work, as discussed in later sections, 3D models of pallets and bricks were placed into the virtual environment. This simulated environment, ascribed in Figure 2, is an ideal representation of the physical robot arm, and its implementation, that is underway at the time of writing.

Traditional Teleportation Interface

Prior to developing the proposed MR HRI interface, traditional modes of robot teleoperation were simulated. One of the common modes a robot arm is controlled via keyboard inputs. The developed control algorithm enables the robot's end effector to translate along the horizontal and vertical, while the gripper can be manipulated via two separate keys, as documented on Table 1. The underlying control algorithm takes the input from the keys and translates the manipulator's end effector target vector, in 3D space, by at a constant rate. This effectively provides real-time end effector control via keyboard inputs. Teleportation is commonly coupled with visual input systems to provide a real-time view of the robot's workspace, when it is operating at an inaccessible setting. In the real-world, this is often done by fix mounting an RGB camera that has a direct line-of-sight to the robot's workspace. A monocular (single-lens) camera was integrated into the virtual environment, presented in Figure 3, to provide the operator with a view of the robot arm's workspace for teleoperation via keyboard inputs. This achieves a simulation of a traditional teleoperation method which will be used for comparison with the MR HRI interface.

Mixed Reality Teleoperation Interface

The first sub-component of developing the proposed MR HRI interface was to simulate a real-time FPV stereo view from the robot arm's end effector, utilizing the Meta Quest 2 VR HMD. The ZEDM stereo camera, by StereoLabs, is able to provide human-like perception. This stereo camera system was integrated into the simulation by hierarchically attaching a 3D model of the camera to a CAD modelled, and maneuverable, servo actuated two-axis gimbal, shown in Figure 4. The objective of this system is to receive real-time orientation data, of the HMD, and map its rotations about the simulated servos y-z axis. This enables real-time head tracking of the operator, presented in Figure 5. Natural head-tracking is of significance as MR wearable technology is prone to creating discomfort for operators. This occurs when the physical movements of the operator do not align with their sensory input systems (vision, sound, touch). As a result, constructing a one-to-one human-like vision system was a key priority.

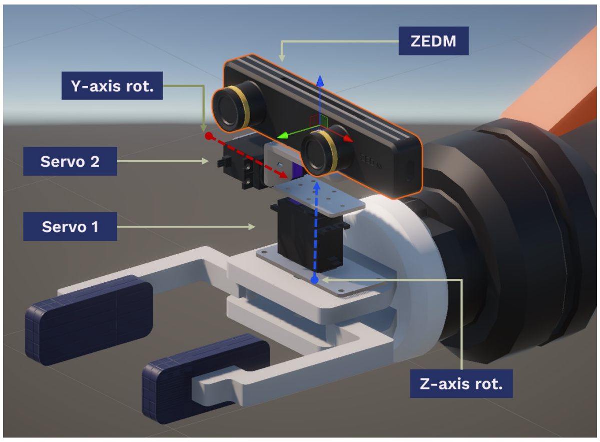

Figure 4: Simulated head tracking 2-axis gimbal system for ZEDM camera.

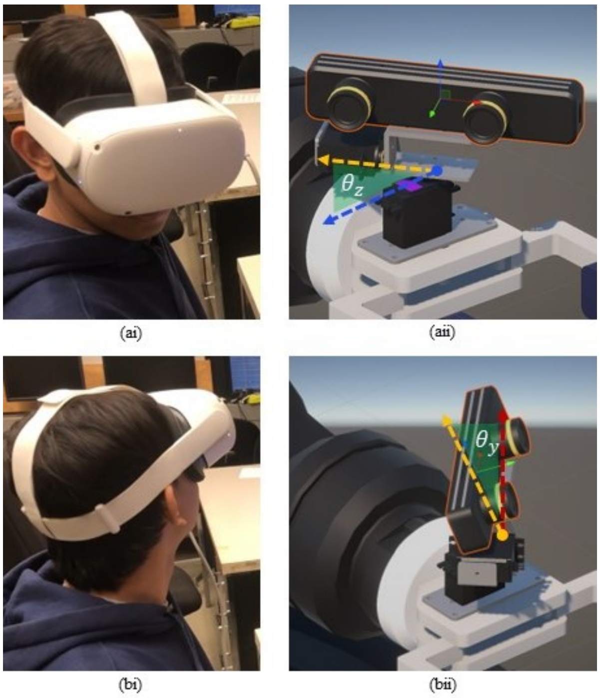

*Figure 5: HMD head tracking system during run-time: **(ai)** operator turning their head towards the right, rotating about the z-axis by angle θ_z ; **(aii)** 2-axis gimbal rotating the z-axis servo by corresponding angle; **(bi)** operator turning their head upwards, rotating about the y-axis by angle θ_y; **(bii)** 2-axis gimbal rotating the y-axis servo by corresponding angle.*

The second sub-component was the integration of real-time hand tracking and gesture detection. The objective here was to provide a mode to manipulate the robot arm using nothing more than the operator's hands, which was achieved utilizing the open-source Oculus Integration package. This is a well-developed library, by Oculus, that provides many features for the HMD including access to IMU data, hand tracking, and spatial mapping. The hand tracking functions by utilizing the 4 onboard multi-camera system of the HMD. Utilizing this library, a VR rig was setup in the virtual environment, with the integrated hand models, to render the tracked hand data in real-time. To perform gesture detection, such as pinch recognition, algorithms were written to measure the relative separation of individual joints in 3D space. Figure 6 diagrammatically shows the real-time hand tracking and how simple gestures are detected.

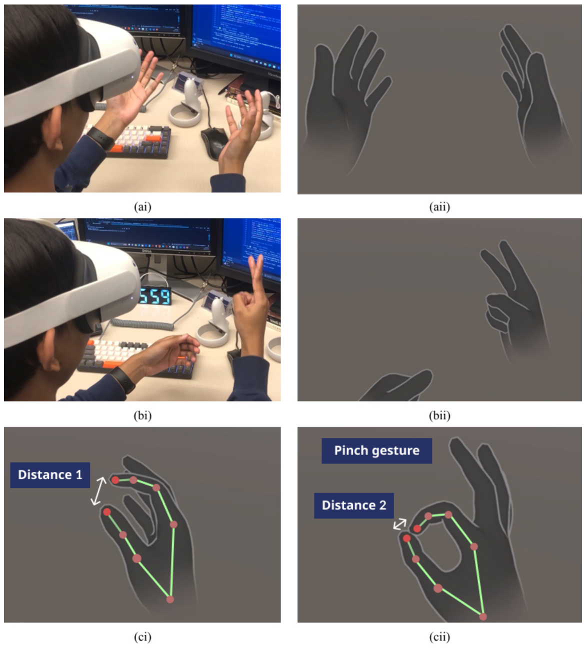

Figure 6: (ai, aii, bi, bii) demonstrates the implemented real-time hand tracking system with the Meta Quest 2 HMD. (ci, cii) demonstrates the pinch gesture being detected by measuring the separation between two joints.

To manipulate the end effector, the tracked hand models were fused with the stereo camera vision system. The result is a full situational aware FPV of the robot arm's end effector with the users tracked hand models. To move the robot arm using the hand tracking system, a Control Sphere was designed. The Control Sphere consists of two 3D virtual models of translucent spheres, one with a smaller radius than the other, anchored at the center of the larger sphere, spatially mapped onto the robot arm's end effector. The outer sphere, with radius R_2, is the Movement Sphere, and the inner sphere, with radius R_1, is the Gesture Sphere, described in Figure 7. When a tracked hand model is inside the Movement Sphere but outside the Gesture Sphere, a vector, from the 3D position of the hand model to the Control Sphere center, is computed and normalized. The resulting unit vector is indicative of the direction the operator desires to move end effector. The robot arm's target tracking algorithm is updated by taking the sum of the current target position with the product of the unit vector and a constant multiplier. The result is the end effector moving in the vector direction, relative to the center of the Control Sphere, as input by the operator's tracked hand models, providing omnidirectional control. When the tracked hand models are within the Gesture

Sphere, the tracking target's movement speed is set to zero, effectively pausing motion control. Users are then able to input hand gestures within this sphere, such as pinching the thumb and index fingers together, to close the gripper and releasing these fingers to open the gripper. Equation 1 computes the relative position vector between the tracked hand model to the center of the Control Sphere while equation 2 normalizes the position vector. In equation 3, the variable Δt corresponds to the elapsed time between the current and previous frame in the simulation while C is a constant multiple to set the movement speed of the manipulator. The updated target tracking position, $\vec{\mathbf{T_{t+1}}}$, is computed, taking into account its current position $\vec{\mathbf{T_t}}$. Figure 8 shows the described mixed reality HRI system, at simulation run-time, for moving the manipulator and grabbing objects, using the hand tracking system.

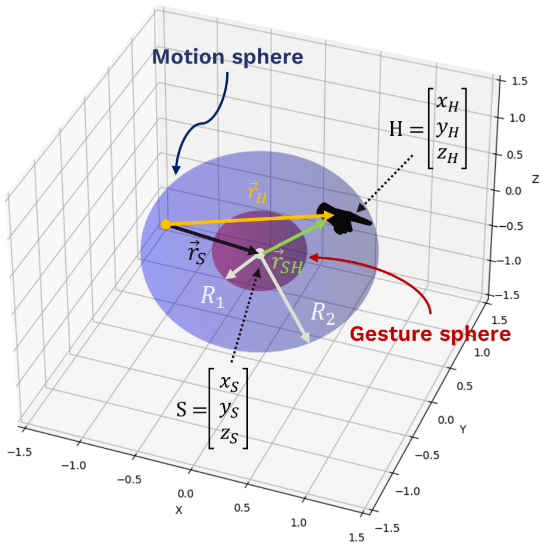

Figure 7: Diagram of the Control Sphere structure used to control the robot arm.

$$\vec{\mathbf{r_{SH}}} = \vec{\mathbf{r_H}} - \vec{\mathbf{r_S}} = \begin{bmatrix} x_H - x_S \\ y_H - y_S \\ z_H - z_S \end{bmatrix} \tag{1}$$

$$\hat{r_{SH}} = \frac{\vec{\mathbf{r_{SH}}}}{|\vec{\mathbf{r_{SH}}}|} = \frac{< x_H - x_S, y_H - y_S, z_H - z_S >}{\sqrt{(x_H - x_S)^2 + (y_H - y_S)^2 + (z_H - z_S)^2}} \tag{2}$$

$$\vec{\mathbf{T_{t+1}}} = \vec{\mathbf{T_t}} + C\Delta t \times \hat{r_{SH}} = \begin{bmatrix} x_t + C\Delta t \times \hat{r_{SH_x}} \\ y_t + C\Delta t \times \hat{r_{SH_y}} \\ z_t + C\Delta t \times \hat{r_{SH_z}} \end{bmatrix} \tag{3}$$

Experiment Setup

An experiment was devised to compare the implemented MR HRI system to the traditional monocular fixed-view keyboard teleoperation method. The goal of the experiment was to observe trends relating to depth awareness, overall situational awareness, and task completion efficiency. The experiment consisted of driving the robot arm, from its starting position, to a brick, that is placed on a pallet, with the goal of moving to the position where the brick would be in between the gripper, as shown in Figure 9. To collect data during run-time, C# scripts were written to store the coordinates of the end effector, along with the elapsed time, between iterations. Each teleoperation method was executed by the same operator 5 times. The raw flight path data will be indicative of depth perception and situational awareness of the operator while the time to minimize the distance to the target will be indicative of efficiency.

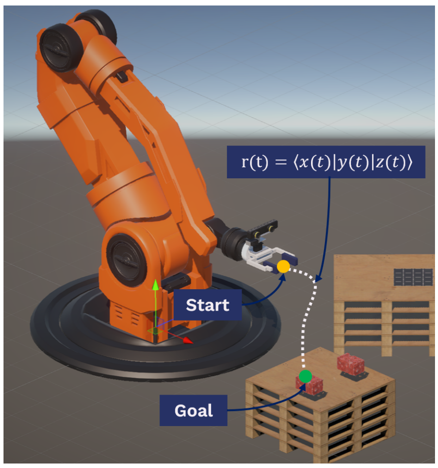

Figure 9: Experiment Setup

Results

The trajectories of the robot arm's end effector for each of the 5 runs of the monocular fixed-view keyboard teleoperation is shown in Figure 11a). The trajectories of the robot arm's end effector for each of the 5 runs of the MR

HRI teleoperation is shown in Figure 11b). A side-by-side comparison of both teleoperation modes, for each run, is shown in Figure 11c). Inspection of the trajectories of the monocular fixed-view keyboard teleoperation method demonstrates irregular flight paths on each of the runs. The flight path trends show two distinct patterns: simultaneously moving forward and laterally towards the target followed by an immediate singular lateral movement. The inability to maintain a smooth trajectory indicates a lack of depth perception of the robot's workspace. Inspection of the trajectories of the MR HRI teleoperation method demonstrates consistent and smooth flight paths on each of the runs. Each of the trajectories has the properties of a direct vector, from the starting pose to the goal pose. This suggests that there is a high level depth-awareness and situational awareness of the robot's workspace. The side-by-side view of both teleoperation methods demonstrates this difference in operator awareness.

The time to complete the task for each teleoperation method and runs are shown in Figure 10a). The number of iterations in the simulation each teleoperation method took to complete the task for each of the runs is shown in Figure 10b). Upon initial inspection, both teleoperation methods are observed to complete the task, per run, approximately around the same duration of time. The results show the traditional monocular fixed-view keyboard teleoperation method completes the task quicker, in some runs, than the MR HRI method. This is contradictory to the trajectory results as the MR HRI method moves in a direct path to the goal pose while the traditional method has an indirect path. Furthermore, for both teleoperation methods and all simulation runs, the robot arm was set to move at the same constant velocity. Inspection of the number of iterations for each of the runs shows that the MR HRI system completes the task in approximately 2.5x fewer iterations than the traditional teleoperation method. Therefore, the longer task completion duration for the MR HRI method is hypothesized to be due to its higher computational demand compared to the simplistic keyboard teleoperation method. The MR HRI simulation takes longer to execute a single iteration, or a lower frame rate, resulting in a longer simulation run-time. However, it is evident that the MR HRI system is able to minimize the same distance to the target as the keyboard teleoperation method with fewer iterations. To truly understand the relationship between task completion time and the two teleoperation methods, a real-world implementation is required.

Conclusion and Future Work

We proposed and implemented a mixed reality human robot interaction system for a 4-DoF robot arm. The results of the our architecture demonstrate a higher operator depth perception and situational awareness of the robot's workspace compared with a traditional monocular fixed-view keyboard teleoperation method. Supported by stereo vision systems, a head mounted display, and hand tracking algorithms, the operator is able to manipulate the robot arm's end effector safely and efficiently to perform simple construction tasks, such as picking up bricks in a simulation environment. The modularity and mechanics of the MR HRI system will enable the control of various real-world robot arms, rather than a select few. The system alleviates the need for on-site construction workers, greatly reducing accidents and serious injuries in construction sites. Rather, the system enables operators to utilize their knowledge and expertise from a safe distance, performing intricate tasks while simply wearing an HMD. Future work will require the extension of the MR HRI system to a physical robot arm. At the time of writing, a successful implementation of real-time hand tracking with the real-time stereo vision of the physical ZEDM camera has been completed. Next steps will include the development of a two-axis gimbal, to mount the vision system, to demonstrate HMD tracking. Additionally, control algorithms to interface between a physical 4-DoF robot arm and the MR HRI system will be developed. A test with a physical robot arm will provide important data on task completion efficiency, operator training, and robot control accuracy.

INPUT STRATEGIES FOR PRECISE CAD MODELLING WITH MODERN INTERACTION DEVICES

Markus Berger[1], Jörn Plönnigs[1], and Martin Wogan[2]

[1]University of Rostock, Rostock, Germany
[2]TU Dresden, Dresden, Germany

Abstract

The release of ever more capable wearable display and interaction devices, like Apple's Vision Pro or the Meta Quest line of products, and the continuous change in the mobility of engineering work, enables new means of interaction with Computer Aided Design (CAD) software. This includes new input modalities that go beyond traditional mouse and keyboard interfaces. In this paper, we want to analyse these new input devices in the context of 3D CAD modelling tasks, and compare them to more conventional interfaces to see in which scenarios they may be most productive and where challenges lie on the way ahead.

Introduction

Computer Aided Design (CAD) was one of the initial innovation drivers behind the development of novel human-computer-interfaces like the mouse from Engelbart et al. (1965) or the stylus (light pen) by Sutherland (1964). Since then, the combination of mouse and keyboard established itself as the common way to model objects in CAD software. It allows designers and engineers to select objects, draw shapes and input numbers and text data quickly and with minimal movement affecting fatigue. However, Engelbart et al. (1965) never intended it to be used in 3D. Any modelling task that requires 3D inputs relies on either special key-combinations to add 3D translations and rotations, or on dedicated 3D-input devices, like 3D-mouses or trackballs, which add additional axes of inputs. Sans such devices, the 2D mouse is still the most common input device, simply because of its ease-of-use and due to the fact that most displays are still 2D.

This situation is shifting nowadays, with modern immersive display hardware, like VR (Virtual Reality), AR (Augmented Reality) or MR (Mixed Reality) headsets or high-quality stereoscopic 3D screens being more commonly available. Here, the models are actually shown in 3D space and mouse inputs quickly fail to compensate the missing third dimension. New specialized input devices become a necessity. Similar issues are observable with portable touch devices. Tablets and phones initially just emulated the mouse and keyboard and provided mouse-like touch inputs and virtual keyboards. However, most of the efficiency of these input methods vanished in practise. Specific multi-touch input gestures and swift keyboards developed, which proved more appropriate for most modelling tasks. But none of the finger-based touch interaction concepts have become established in CAD, primarily due to their inherent precision issues (Benko and Wigdor, 2010).

AR and VR systems on the other hand are recently experiencing a move away from physical controllers and towards fully hand-based interactions. These hand tracking systems are either used to simulate a full hand within the virtual space, in which the physicalized live shape of the hand is pressing buttons and touching elements (Meta Quest), or they recognize specific hand gestures and translate these into space, for example by combination with eye gaze (Apple Vision Pro, Microsoft HoloLens). While selection tasks and other simple interactions can be effectively represented, inputs that require high precision can be an issue. Additionally, the more specific interaction techniques are, the more difficult it is to achieve broad support for them in 3D CAD software.

Nevertheless, 3D headsets and touch devices have huge potential to enable new approaches to immersive design, where people in different physical locations can collaborate on a virtual model, and make changes by interacting with virtual objects through the same direct means they would use with physical models. How intuitive would it be if we could move weight bearing pillars in CAD as simply as furniture in the real world, in the process getting a feeling for the weight, the pressure, the sound absorption, and the touch of the material, and then still have the capability to position it down to millimeter precision?

To achieve this, we need to first solve the precision problem. Only once these novel interaction techniques can reliably achieve the same, or better, results than traditional interfaces will we see broad adoption in professional CAD software. For this, we have to learn from the dominant paradigms of mouse and keyboard and touch and stylus interfaces, which crucially are *bi-manual combinations* of two input modes that seems to net appropriate levels of precision. In the following sections, we want to answer the question of why that is, and how we can emulate this for arbitrary use cases involving any type of display and interaction device. To achieve this, we do the following:

- We discuss related literature from engineering design and Human-Computer Interaction (HCI)
- We define what common types of inputs and input devices exist and what their important attributes are
- We evaluate these types and devices according to several input metrics
- We apply these insights to three 3D CAD use cases
- We describe possible avenues of research that could lead to better CAD input systems

State of the Art

The question of which 3D input devices are useful for modelling tasks predates the advent of current generation AR and VR. For example, Fiorentino et al. (2010) states that “while planar features modelling performs well with mouse and keyboard, Direct Modelling benefits from bi-manual interaction, six degrees of freedom input (6DOF) and 3D snapping.” They also already distinguish between use cases, where a VR system for conceptual design has different input requirements than mechanical CAD modelling on a 2D screen. For the latter task, they consider the effectiveness of different 6DOF haptic input devices for 3D rotations, and which input methods are most effective for them. In this case, devices are distinguished by aspects like the shape of their transfer function from device to display or how the device responds to muscle force being applied to it.

The literature also features many other input-system specific measures of accuracy. There are attempts to improve typing speed on keyboards (Jiang et al., 2020), studies about the ideal way to implement pointing tasks with VR controllers (Allgaier et al., 2022), accuracy of gaze-tracked inputs (Schuetz and Fiehler, 2022), and much more. Most of these papers focus on individual tasks. Overviews of how these systems fare over all task in multi-input device for multiple purposes are much rarer.

More direct quality metrics used in HCI research are the concepts of resolution and throughput (Bérard et al., 2011). Resolution describes the smallest displacement that an input device can measure, while throughput describes the average rate of information generated by a series of movements (Fitts, 1954).

In addition to these often well-researched common input devices, various dedicated experimental interfaces exist in the literature. Lemberski and Hemmerling (2010) turned an audio mixing device into a dedicated CAD controller, in which 10 faders control 10 parameters in the CAD modelling process. The advantage of a physical interface like a fader, is that their physical position reflects their absolute value. Sharma et al. (2011) created a multimodal system in which touch-based menu controls are replaced by voice commands, and the modelling is done with touch inputs. Specifically, this is about using voice and touch in the early design stages, when exact values are not necessarily that important. Research like this highlights that we may have been trained to think that precision is important above all, as the interfaces we currently use do not distinguish between early stage and late stage modelling precision. If all a keyboard can offer is precise numerical inputs, then precise numerical inputs is how we will approach modelling. Sharma et al. (2011) write that “it is commonly observed that designers prefer pen and paper for early stages of design”, which is most likely the case for this exact reason.

Parameters of CAD Input

While the literature features many precise quantitative measurements of precision and throughput, we want to propose broader, qualitative categories like: Can this device be used in the field? Are precise inputs even possible? Does using this device for prolonged periods get tiring? For this, we first need to establish a more systematic understanding of CAD inputs that stay relevant across many classes of interaction devices. This will aid us in establishing quality metrics that can be used as the basis for creating CAD interaction systems for arbitrary use cases and display setups.

Classification of Input Tasks

Fiorentino et al. (2010) “consider CAD modelling as a sequence of picking and navigation (rotation) actions”. More generally, they define four basic classes of CAD input tasks: *navigation and travel, selection, manipulation* and *system control*. We will base our analysis on this categorization, but will differentiate between spatial manipulations and numerical manipulations. *Spatial manipulations* involve the placement of points, drawing and alteration of lines and surfaces by direct spatial input. *Numeric manipulations* involve the input of numbers in relation to some part of the CAD model, for example by constraining the length of a wall to a specific precise length. Both of these interactions can have different levels or precision, depending on input devices. A mechanical slider like found on MIDI boards could potentially offer very precise inputs, compared to a completely virtual touch slider, as there is an inherent amount of smoothing and inference when dragging a finger over a touch surface.

Figure 1 shows the input tasks with their associated set of common operations. The input types are arranged in two classes—those that have a direct reference to the model being designed, and those that are used to put the software context into the proper camera position and program state to enable the next direct modelling steps.

Each task can be resolved in different way, depending on the input devices. Specifically, we will distinguish three classifications of input devices, which we will discuss in relation to selection, spatial manipulation and numeric manipulation tasks respectively.

Spatial Reference

Selection tasks happen at different resolutions, from object-level to the level of individual points on a geometry. The aspect that distinguishes them from each other more than anything however, is whether we select points

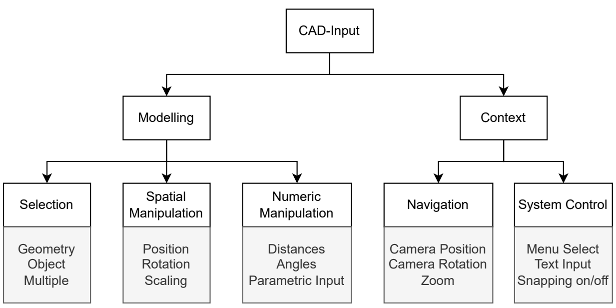

Figure 1: Hierarchical classification of CAD input tasks.

based on some projection to 2D (e. g. mouse with trackball), or whether the device can immediately reference 3D points independent of a display surface. Fig. 2 highlights this difference.

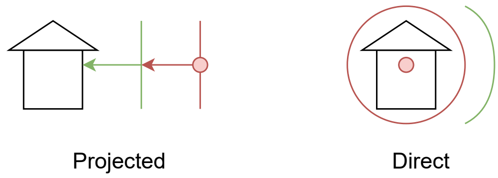

Figure 2: Green shows where the display is, red shows the interaction device, black denotes the object being selected.

Input Reference

Similar to selections, the way an input device does spatial manipulations will be most impacted by whether the device is creating a sensation of immediately interacting with the manipulated object, through a touch screen or in a midair 3D projection, or whether device movements happen on an unrelated surface or space and are somehow translated into the model. Figure 3 shows this distinction between translated and immediate inputs.

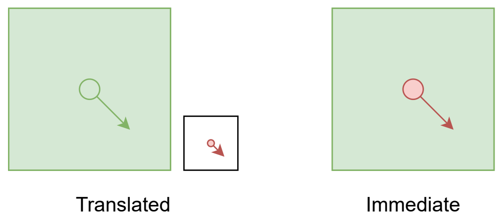

Figure 3: The green boxes represent a display device, the black box a separate zone of interaction. Red highlights the point where the input physically takes place.

Input Progression

Numeric inputs are distinguished by the basic fact of whether we are inputting the numerical value explicitly as a series of digits (usually to a high degree of accuracy), or whether we are providing a way to move as close as possible to it. The advantage of exact inputs is that the user can quickly set a-priori known values quickly—the disadvantage are case where the value is not known, like alignment cases. A system that allows for a continuous approach towards a value allows us to experiment with placements and sizes in a way that exact measurements do not. Though most relevant to numeric inputs, the capability to input numbers can have an impact on every kind of interaction, for example to select the scale at which a specific spatial operation should be resolved. Figure 4 highlights the process of these inputs over an imagined number line.

Input Devices

The main reference device for our analysis is the traditional combination of **mouse** and **keyboard**. The mouse usually acts as a combined selection ("Take *that*...") and spatial manipulation input ("...and put it *there*...") with reasonable accuracy, often supported by acceleration features. Meanwhile, the keyboard is used for numerical ma-

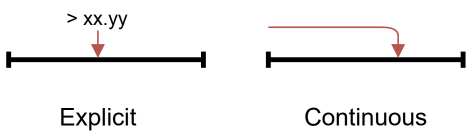

Figure 4: Numeric inputs are often collected by linear interfaces (e.g. slider). A device either moves from one side to the other (red line), or snaps to specific value on the line (red arrow)

nipulation ("...*there* being defined as *exactly*..."), but, often also provides alternative selection and manipulation key combinations. Individually and in tandem they also provide easy navigation and system control inputs. As stated in the introduction, this does not translate efficiently to 3D displays. This lack of good input devices is one of the main reasons, why we do not design in 3D[1]. Regardless of any other considerations, any alternative input system must be able to offer at least a degree of precision and throughput that gets reasonably close to what a mouse and keyboard can achieve. What is "reasonable" depends on the specific use case, as will be discussed later on in the paper.

The class of touch devices is one potential alternative interface technology. Here we use a pointing device (e. g. a stylus or our fingers) often on a surface (e. g. screen, touchpad, tablets) with different gestures (e. g. tap, one-finger slide vs. two-finger drag) to realize various inputs. The most useful distinction for our purpose here is simple **touch** vs. **multi-touch** with the finger modality, and then specific **touch devices** like a stylus, which can also be combined, like shown in Pfeuffer et al. (2021). The benefit of those inputs is that they are very intuitive and easy to learn. Traditionally those interfaces were 2D, but, nowadays are sometimes translated into the 3D world by devices like the **3D-stylus** by Jackson (2020). Sometimes, a 2D stylus is also used on a specific, external **drawing tablet**. When used like this, it is similar to a mouse, but, has additional sensors for pressure.

Then, there are devices that use more novel input systems with a touch-metaphor. This is the case for both the Meta Quest (menu controls often use hand movements as a touch-analog, like the swipe of the hand modelling a finger drag) and the Vision Pro, which both offer gesture control modes. In case of the Vision Pro, a combination of **gaze** and gestures enacts the same types of inputs like Apple touch devices, thus enabling cross-platform compatibility. The main distinction here is between **direct gestures**, which are done in direct contact with an object, and **indirect gestures**, which are done somewhere in space and area in some way related back to the object in focus. Apple (2024) makes this distinction explicit in their developer guidelines. Indirect gestures are those that work in tandem with gaze to implement common touch gestures from other platforms: Tap, Swipe, Drag, Touch (or pinch) and

[1]The lack of abstraction is another one. 2D plans actually enforce a simplification that is removing visual clutter and allowing users to focus on the relevant visual information. However, we know how to generate good, simple 2D views from 3D. So, it is technically a solved issue.

hold, Double tap, Zoom, Rotate. Direct gestures are a new addition specific to their AR platform and include the following: Touch, Touch and hold, Touch and drag, Double touch, Swipe, Pinch and drag two hands together or apart, Pinch and drag two hands in a circular motion.

A more specialized type of interaction hardware are controllers of any kind. These can include game controllers or even devices like MIDI controllers. These have in common that they combine multiple smaller input elements into a usually very ergonomic device. They feature devices like **buttons and triggers** (with just a few, sometimes analog buttons, as opposed to the many buttons on a keyboard), **analog sticks**, and **sliders and knobs**. These types of controllers are usually not tracked in space. Buttons and triggers are also usually part of other devices and are not deployed on their own. For the purposes of this paper, the class of analog sticks also encompasses any static 6DoF (Degrees of Freedom) controller, like 6DoF joysticks or 3D mouses.

A tracked extension of them are **motion controllers**, today mainly used for VR. These reduce the controller paradigm to what can comfortably be used in one hand, and add object and sometimes hand tracking to it. As such they model human hands, but other than direct hand gesture inputs they offer some translated inputs like analog sticks and triggers. Some motion controllers eschew additional controls and are instead focused on tracking and input accuracy—these types of controllers are equivalent to the aforementioned 3D stylus.

Some older VR controllers as well as controllers for room scale large display systems are only tracked in rotation to implement a laser pointer-like interaction. We will call this class of devices **3D pointing device**.

Finally, there is **Voice** control. Although this modality has fallen in and out of favor over the years, there could be great potential in using it in tandem with manual devices, specifically when these devices occupy both hands and can not by themselves cover every needed input.

Evaluation

In this section, we will take the previously established input types and devices, as well as their categorizations and evaluate them over some common metrics. This will yield a qualitative overview of which devices are appropriate for which use cases and how they can be combined.

Metrics of CAD Input

We first define some metrics to compare the different input devices in applicability to CAD design. Our metrics are based on the common quantitative metrics resolution and throughput defined for example in Bérard et al. (2011). *Resolution* is defined as the smallest possible displacement of an input device that can be attained reliably and quickly (i. e. with one short motion). *Throughput* describes, simply said, the average information an input device is capable of creating for the modelling task by a trained user. We distinguish in spatial throughput for spatial inputs, and numerical throughput for numerical inputs.

We redefine these metrics as *Precision* and *Capability* to make them qualitatively evaluateable and extend them by *Explorability* as follows:

Precision (Resolution) How precisely can we input the information into the model and how error-prone are inputs?

Capability (Throughput) How quickly can we get the needed information into the model and how much range do we have for the inputs?

Explorability Can we quickly try out variations while we input information into the model, for example by moving a control back and forth?

All apply to both spatial and numerical inputs, though they refer to slightly different aspects for both. For Selections, Navigation and System Control, we only consider a generalized *Effectiveness* metric. Explorability is a secondary metric that derives from both the throughput of a device and which input classes it falls into.

Apart from the direct input metrics, there are also metrics set by the context of use. Do we need a portable device? How many hands do we have free? Are we building robust systems for experts or trying to invite the general public to play around with modelling? Secondary metrics are:

Hands Is an interaction uni- and/or bi-manual?

Intuitive Are the interaction concepts intuitive?

Portable Can the input device quickly be used in the field?

Collaboration Does the input device allow for dynamic collaboration of multiple in one room, on the same reference display or projection?

Comfort Is the device ergonomic, and is using it not tiring even when used for hours on end?

Support How well is this type of device supported in common 3D CAD software today?

Factors like portability, software support can usually be easily determined based on experience with how these products are used in practice. Intuitivity and comfort are more complex psycho-physiological measures, but are still commonly studied metrics in the HCI literature (e.g. in Stern et al. (2008) and others referenced in Table 1).

Comparison of CAD Input Devices

With these types of inputs and metrics of quality established, we can consider which input devices are effective for which kind of inputs. A qualitative classification of this can be found in Table 1. We first compare all input devices based on the use case metrics and specify whether the device intuitivity, portability, collaborativity, comfort, and current support are low (▼), medium (◆), or high (▲). We then specify in which spatial reference, input reference and numeric input the device falls and evaluate the effectiveness of the device to execute selection, spatial inputs and numeric inputs. For the latter two we evaluate the precision, capability, and explorability individually and for the first one the overall effectiveness. We do the same for the effectiveness for navigation an system control. These evaluations are, where possible, based on results from the lit-

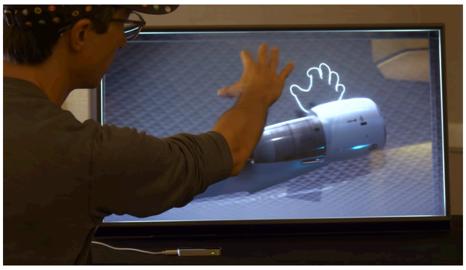

Figure 5: User interacting with a holographic display. Source: Looking Glass

erature. Example references are given at the end of the table. This table can be used to prioritize the quality measurements important for a specific use case, and quickly compare and identify appropriate input devices. Input devices can also be combined in any way until both hands are full, or if they are portable enough.

There are of course other possibilities than the ones shown in the table, like direct numerical inputs with the mouse by clicking on a virtual keyboard. However, we want to consider only inputs that are actually common in practice or could possibly become important as new display and interaction modalities are unlocked through AR and VR technologies. Many input methods allow for the use of virtual keyboard, but they will usually have lower precision (because of being error prone) than a physical keyboard, as well as much lower capability, and as such have never gotten a large amount of adoption.

Discussion

In order to show how to use this evaluation in practice, we will consider three input scenarios that are not currently common in CAD modelling, but could become more commonplace in light of recent technological advances.

Scenario 1: Single person, 3D Display

This use case is aimed at a trained user drawing up an entirely new model from scratch on a CAD workstation with a holographic or high-quality stereo display, capable of displaying models with 3D depth, or even fully volumetric displays as shown in Fig. 5. The user can see all input devices and there is no occlusion, as will be discussed in the second scenario.

The most important input types here are spatial, numeric and system control, and within the former two both precision and capability play a large role. As far as the secondary metrics go, the most important one is comfort, as expert users in such a system would be expected to work for hours uninterrupted.

According to Table 1, the following devices would be appropriate choices to fulfill all or some of the requirements:

- Mouse/Drawing Tablet (For translated inputs and system control)
- Keyboard (For numeric input and system control)
- 2D Touch Stylus (For immediate inputs)
- Sliders/Knobs (For continuous numeric inputs)
- Trigger/Buttons (For system control)

All of these devices can offer comfortable working conditions, depending on display-setup. For a touch stylus to be comfortable for hours, the display should be slanted beneath the user, something that may not be ideal when utilizing a 3D display. The issue with simply using mouse and keyboard is the fact that the display projects a 3D image. The 2D-based translated projection of the mouse will still work relatively well for selection tasks, however the translated spatial inputs are similarly projected into 2D, which will not be sufficient for a true 3D context. Instead, we need input with a high *comfort* level, a *direct* spatial reference and an *immediate* input reference. If we consider all options in Table 1, there is no combination that covers all three of these aspects perfectly. A 3D stylus would be the best option, but will not be comfortable for hours, even with for example an elbow resting on the table in front of the screen. In lieu, we could combine a mouse or drawing tablet for precision spatial inputs on the model in the current camera view, and the ability for the user to reach into the model with direct gestures whenever necessary. This way we achieve the direct and immediate inputs, without having to regularly grab a new input device.

To promote the gesture paradigm, we could include indirect gestures for system control, thus making the weak hand the "gesture" hand while the right hand is kept on the mouse. This only creates an issue in that it would be awkward to have a full keyboard in the same space in which the hand is frequently moving down onto the table for indirect gestures and up from the table for direct gestures. Here, we could instead use a special control board with sliders, knobs or buttons with the left hand, to do additional system control and to input continuous numeric values whenever necessary. If a direct numeric input is necessary, the user can use voice control to say the exact numbers needed.

Scenario 2: Single person, VR Glasses

In this input scenario we imagine an architect or civil engineer working on a CAD model that features drastic scale differences in individual parts. The user needs to be able to change camera position and scale within the world on the fly, in order to place themselves in front of a part, while also seeing as much of the surrounding context as possible. Because of the limited virtual view that a 3D display would offer, we need to utilize a VR headset to properly display the model context. This creates an issue with the input devices we used in Scenario 1: they would now be fully occluded by the virtual world. This means that the user cannot see their interaction with the input devices and could potentially lose their positioning after looking away from their focus point. Thus, all input devices that we use in this scenario should be tracked in 3D space, in order to place avatars of them into the virtual space. This is most feasible with any input device that has an immediate input reference and direct spatial reference, as well as any type of input that does not require a device at all:

- Gaze (Selection)
- VR Motion Controllers (For spatial and numerical

Table 1: Comparison of various input devices in their effectiveness for certain CAD editing tasks. For spatial and numerical inputs, effectiveness is split into the three quality measures precision/capability/explorability. We evaluate in: ▼- low, ♦- medium, ▲- high effectiveness.

manipulation, navigation)
- 3D stylus (for precise spatial manipulation)
- Direct Gestures (Navigation)
- Indirect Gestures (For system control)
- Voice (For numeric inputs and system control)

The occlusion removes several interfaces that strongly depend on a good hand-eye-coordination like the mouse, keyboard or 2D stylus devices from our list. VR motion controllers or 3D styluses are better suited as they can be synchronized in the 3D model and users have a hand-eye-coordination feedback loop as shown in Fig. 6. One issue is that none of these devices offer high precision *and* a high comfort level. It is however unlikely that a user would wear VR glasses for a complex, multi-hour interaction process. Instead, this system is more likely to be deployed only once a high degree of spatial awareness is necessary. If longer working times are expected, we could in a first step either create more involved indirect gestures that also allow for numeric inputs, or for long-term work even create a custom tracked solution based on sliders, knobs and buttons.

Scenario 3: Collaborative, VR/AR Glasses

For this scenario, we imagine a group of designers doing design ideation around the same 3D model. They can twist and turn the model as well as highlight and switch out parts. The most important aspects here are selection, navigation and spatial manipulation. Hand-free interactions are more relevant than precision for this. While the input reference should be immediate, a direct spatial reference is not absolutely necessary. In this collaborative setting, users are expected to sit around a table in a relaxed manner, and will thus be relatively far from the model.

- Gaze (For selection)
- Indirect Gestures (For navigation and spatial manip.)
- Voice (for direct numeric input and system control)

Until recently, Microsoft's HoloLens display was the most prominent system that could implement this combination of inputs. However, display quality and depth of interaction was limited. Recently, the Vision Pro glasses by Apple have further developed this paradigm. What the Vision Pro offers us is a "Gaze and Gesture" input system as shown in Fig.7. Following Table 1, it is fit for comfortable collaboration, and can deliver reasonably well on selection, spatial manipulation and navigation tasks. We suggest a mapping of indirect gestures to common tasks in Table 2. The only issue is the precision of gestures in spatial manipulation. Placing parts in the model that is several meters away by hand gestures can be jittery and error prone. As such, these inputs should be transformed into step-wise numerical inputs with indirect gestures that mirror multi-touch gestures, and optional voice input for the highest precision.

Summary and Future Work

In this paper we review various classes of currently available input devices for CAD modelling applications. We identified commonalities and differences between these devices and categorized them according to multiple factors. Then, we established qualitative metrics for evaluating their expected performance for different input tasks. This being early stage research, the considerations were not validated quantitatively in a usability study. This is future work. We then applied these metrics to three use case scenarios that could profit from making use of novel display and interaction devices, discussing individual drawbacks of the device classes in context, and referencing specific actually existing devices where appropriate.

Establishing new input modalities is as much a process of breaking habits as it is of building effective devices. The issue that most new devices encounter, is that mouse and keyboard do most things very well, and specific 3D tasks reasonably well. A new device that does better at specific 3D modelling tasks will always have to compete with the broad usefulness and software support of paradigms like mouse and keyboard. Specific devices will be limited to specific software, a circumstance that can create enough inertia that even useful techniques do not end up in mainstream CAD software. However, in the near future we can expect a broader adoption of VR and MR devices—which has the capacity to break some of this technological inertia and thus introduce whole new device classes into the public mind. CAD software should prepare for this now, in order to exploit entirely novel possibilities offered by some of these technologies. There is potential for systems that make it easier to draw organic shapes for 3D printing applications, or inputs that natively include AI-assisted interactions, combining the precision of a manual stroke with the *intent* behind it.

A FIRST EVALUATION OF THE SEAMLESS MARKERLESS AUGMENTED REALITY REGISTRATION SYSTEM SUPPORTING FACILITY MANAGEMENT

Leonardo Messi, Francesco Spegni, Massimo Vaccarini, Alessandra Corneli, and Leonardo Binni
Università Politecnica delle Marche (UNIVPM), Faculty of Engineering, DICEA Department, Ancona, Italy

Abstract

Augmented reality (AR), despite its great potential, still struggles to be widely used in real construction processes due to difficulties in registering holograms in mixed indoor-outdoor scenarios. Since a definitive technological solution for inside-out AR registration does not exist yet, a seamless markerless augmented reality registration system, integrating real-time kinematic positioning (RTK), inertial measurement units (IMU) technologies and image comparison based on convolutional neural networks (CNN), has been proposed by the authors. Experiment results have shown the need to continuously register AR at regular temporal interval within 1 seconds and/or 1 meter to achieve "fine-precision" positional accuracy (i.e., 0.10 m).

Introduction

The architecture, engineering, construction, and operations (AECO) sector, despite its reputation as one of the least digitized industries, is progressively embracing digital technologies to enhance various stages of a building's life cycle (Albahbah, Kıvrak, & Arslan, 2021). Among these stages, the operation and maintenance (O&M) phase in facility management (FM) incurs the most significant costs, accounting for 50–70% of annual facility operating costs and a whopping 85% of the overall lifecycle expense (Salman & Ahmad, 2023). As facilities become increasingly intricate, day-to-day tasks have become more demanding. This heightened complexity has propelled the construction industry pursuit of visualization technologies to facilitate better access to information for evaluation, communication, and collaboration.

Augmented reality (AR) technology emerges as a promising tool for streamlining O&M tasks, bridging the gap between facility managers and field workers, thereby minimizing delays and reducing operational expenses (Salman & Ahmad, 2023). AR technology revolutionizes human-computer interactions by establishing direct links between physical and digital realms. Its ability to overlay virtual objects onto the real world allows for the identification of concealed facilities and provides detailed maintenance guidance for field workers (Salman & Ahmad, 2023). However, integrating AR poses technical challenges. While display technology has made significant strides, achieving precise position tracking remains a major obstacle. Spatial registration, ensuring accurate alignment between virtual and real-world coordinates, stands as a critical aspect of AR functionality (Albahbah et al., 2021; Salman & Ahmad, 2023). Spatial registration methods can be categorized as "marker-based" or "markerless" (Albahbah et al., 2021; El Barhoumi, Hajji, Bouali, Ben Brahim, & Kharroubi, 2022; Salman & Ahmad, 2023). Marker-based approaches register virtual models using some kind of physical or hyperlink markers (El Barhoumi et al., 2022). These solutions can be potentially applied in mixed environments, but they generally require a preliminary survey, a manual setup and markers often generate aesthetic issues (Baek, Ha, & Kim, 2019). On the other hand, markerless methods, such as Global Navigation Satellite Systems (GNSS) or image-based localization, solve the previous gaps automating the AR registration process (Baek et al., 2019). However, the former cannot be applied indoor (Chen et al., 2019) and the latter requires a preliminary survey for collecting reference images (Baek et al., 2019; Messi, Spegni, Vaccarini, Corneli, & Binni, 2023) which restricts its use in large outdoor scenarios.

An innovative seamless inside-out and markerless localization system has been developed by the authors in (Messi et al., 2023), housing GNSS-based and image-based registration engines on an AR cloud platform, complemented by a switch engine managing their priorities. Since initial qualitative testing on a university campus has shown promising outcomes, AR registration performances need to be quantified in terms of drifts from an assumed benchmark. Hence, this paper serves as a follow-up to the one presented by the authors in (Messi et al., 2023) and aims to conduct initial assessments of the tracking engines embedded in the proposed system. These assessments provide a first evaluation of the capabilities of our seamless and markerless AR registration system (Messi et al., 2023). Existing studies report different registration accuracy thresholds, such as the "fine-precision" corresponding to 1°/0.10 m, and "high-precision" corresponding to 2°/0.25 m. The first one is considered as the minimum accuracy required for a good AR user experience in most settings (Sarlin et al., 2022; Sattler et al., 2017).

This paper progresses as follows. The Research questions section formalizes the objectives of the study. Then, the Methodology section presents the proposed system architecture and the evaluation method. The Experiments section describes the experiments carried out for the assessment of the drift and related results, followed by the Conclusions section that closes the paper.

Research questions

This study, since the seamless and markerless AR registration system presented by the authors has shown promising outcomes (Messi et al., 2023), carries out an accuracy assessment aimed to quantify its reliability. More in detail, the following research questions have been formalized:

RQ.1. What is the drift of the proposed system during FM operations?

RQ.2. What spatial/temporal AR registration frequency should be ensured to optimize the performance of the proposed system?

Methodology

This section presents the methodology applied by this study. To this purpose, the System architecture section will first recap the architecture of the markerless seamless AR system presented in (Messi et al., 2023), whereas the Evaluation method section describes methodology applied to assess drift issues related to the different registration engines embedded by the system.

System architecture

The architecture of the proposed system (Messi et al., 2023) is established on an AR cloud platform housing four essential elements: (i) the graph database, (ii) the GNSS-based AR registration engine, (iii) the image-based AR registration engine, and (iv) the switch engine (Figure 1). Although this system architecture has been defined for Microsoft HoloLens 2, it applies to all AR devices.

The AR cloud platform serves as a centralized resource for data processing, storage, and distribution. It enables precise mapping of virtual assets to real-world locations, crucial for integrating the virtual and physical realms. Images and point clouds are georeferenced and aligned within this platform using absolute world coordinates and accurate rotations. The graph database manages structured and unstructured data storage, allowing AR application accessibility. The GNSS-based AR registration engine utilizes RTK GNSS and IMU systems for open-space challenges, while the image-based AR registration engine employs convolutional neural networks (CNN) for indoor environments lacking reliable GNSS signals. The switch engine integrates the outdoor and indoor registration engines, facilitating uninterrupted AR experiences by dynamically switching between registration approaches.

The process for GNSS-based AR registration involves aligning the HoloLens 2 local frame to global coordinates using RTK measurements. The system computes the device position and orientation relative to geographical coordinates, enabling precise placement of building information models (BIMs), stored within the graph database. This process accounts for changing observer positions and altitudes, ensuring accurate object positioning and alignment with the local frame. Conversely, image-based AR registration relies on image comparison with survey data collected via cameras and LiDAR scanners. The process involves localizing the HoloLens 2 by comparing its current view with referenced images and related point clouds stored in the AR cloud platform (Sarlin, Cadena, Siegwart, & Dymczyk, 2018). CNNs, namely Hierarchical Feature Network (HF-Net) technology (Sarlin, Cadena, Siegwart, & Dymczyk, 2018), and the Perspective-n-Point (PnP) algorithm (OpenCV, 2023) are applied for accurate 6-degrees-of-freedom (6-DoF) localization. In this way, BIM models, stored within the graph database, can be overlapped to real world. The switch engine seamlessly integrates both registration approaches based on the scenario: RTK-only (mainly outdoor), RTK with images (mainly outdoor), and images only (mainly indoor). It identifies and triggers the appropriate registration engine based on available data, ensuring a continuous AR registration experience.

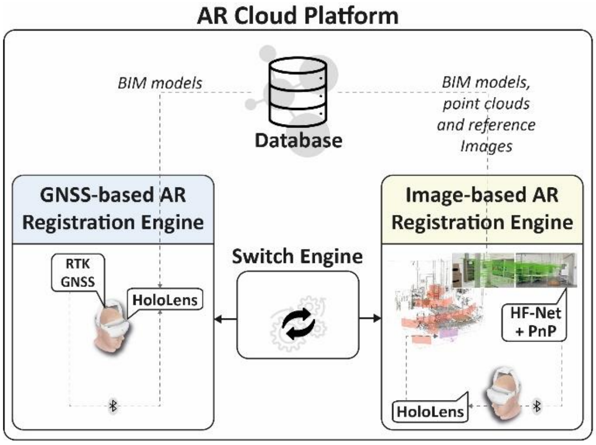

Figure 1: System architecture of the proposed system for seamless inside-out and markerless AR registration.

Evaluation method

For the purpose of a first evaluation of the reliability of the proposed markerless and seamless AR system, a methodology has been defined. It comprises a series of steps aimed at assessing drift values among the tracking engines of the system. More in detail, the methodology defined in this section aims to compare the HoloLens 2 tracking system with both the tracking engines of the system, namely the GNSS-based and the image-based engines. The evaluation steps are reported as follows:

1. **Tracking positions along a route:** this step consists in tracking the AR device position at predefined intervals while navigating a route that includes both outdoors and indoors scenarios. The AR device tracking is carried out using all the different tracking systems described above (i.e., HoloLens 2, GNSS-based, and image-based). The HoloLens 2 and GNSS-RTK tracking devices must be rigidly connected to each other.
2. **Registering HoloLens 2 reference system to the North direction:** this step aims to align the HoloLens 2 system to the North direction using RTK data, by computing the forward azimuth (Movable Type Scripts, 2023) from displacements.

3. **Aligning the image-based cloud system to the HoloLens 2 one:** by aligning the image-based cloud system to the HoloLens 2 one, this step ensures that their x, y, z axes correspond each other and are aligned to the North direction. This alignment is achieved using the position of three reference photos (Schönberger & Frahm, 2016) solely for the purpose of alignment.
4. **Data retrieval of the image-based tracking system:** this step involves calculating displacement vectors (i.e., "tvec" values (OpenCV, 2023; Schönberger & Frahm, 2016) and quaternions (i.e., "qvec" or "rvec" values (OpenCV, 2023; Schönberger & Frahm, 2016)) of the acquired images (i.e., their pose) with reference to the HoloLens 2 reference system.
5. **Data retrieval of the GNSS-RTK tracking system:** this step involves retrieving global coordinates from the GNSS-RTK system, transforming them into x, y, z coordinates using equirectangular projections (ArchGIS Esri, 2023), and computing the forward azimuth (Movable Type Scripts, 2023) of the tracking direction.
6. **Registering and assessing drift between HoloLens 2 and GNSS-RTK tracking:** this step involves calculating the discrepancy between the HoloLens 2 and the GNSS-RTK systems once aligned on the equirectangular projection.
7. **Registering and assessing drift between HoloLens 2 and image-based tracking:** similar to the previous one, this step involves computing the discrepancy between the HoloLens 2 and image-based systems once aligned.
8. **Evaluating drift at regular intervals:** repeating the discrepancy calculations at either specific time intervals (e.g., every 1, 2, 3 s) or distance covered (e.g., every 5, 10, 20 m) to evaluate drift values and assess the best registration frequency.

Experiments

The evaluation method introduced in the previous Evaluation method subsection has been applied to carry out a first reliability assessment of the proposed markerless and seamless AR system. Experiments have been executed assuming a FM use case based on a university campus as a case study. Specifically, the FM of the Digital Construction Capability Centre (DC3) Lab at the Università Politecnica delle Marche has been considered. The DC3 Lab, which covers an area as large as 240 m^2, is composed of a main open space, a changing room, an office, and a restroom. Within this context, the management of the electrical system and, in particular, of the internal electrical panel of the DC3 Lab, has been considered. During this activity, the technician in charge of FM operations spends time first locating the electrical panel. Then, in order to find the root cause of the problem, the technician may be asked to locate cablings associated to the panel, which extend externally to the building. These cablings can be accessed through manholes located on the road in front of the building, connecting it to the rest of the campus (Figure 2).

By testing the system proposed by the authors in (Messi et al., 2023) with the presented FM use case, its reliability in heterogeneous indoor/outdoor scenarios will be evaluated, considering the "fine-precision" positional accuracy threshold (i.e., 0.10 m) and "high-precision" one (i.e., 0.25 m) (Sarlin et al., 2022; Sattler et al., 2017).

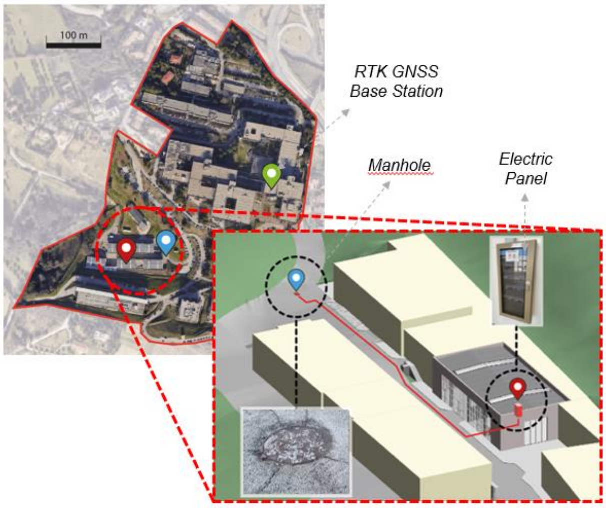

Figure 2: Aerial view of the university campus, assumed as case study, identifying the positions of the DC3 Lab, and the RTK base; The focus on the BIM model of the laboratory shows the positions of the indoor electrical panel and the outdoor manhole cover that are the objective of the simulated FM use case.

Experiments design and execution

In this study, we applied the methodology exposed in the previous Evaluation method subsection to the case study described at the beginning of Experiments section for assessing the outdoor scenario. The indoor scenario and, therefore, the evaluation of drift between the image-based and HoloLens 2 tracking systems will be addressed by future studies. Specifically, in this study, aiming to evaluate drifts between the GNSS-RTK and HoloLens 2 tracking systems (RQ.1) to understand the optimal registration frequency (RQ.2), we implemented points 1, 2, 5, 6, 8 of the proposed methodology (i.e., Evaluation method subsection). Regarding point 1, it should be noted that the conducted experiment simulates the maintenance activity as described at the beginning of Experiments section, following a path in a mixed indoor-outdoor scenario, using the HoloLens 2 device with a rigid add-on hosting the RTK receiver (Figure 3).

With these premises, the experiment was conducted in two parts. The first part involved comparing the GNSS-RTK and HoloLens 2 tracking systems in a mixed indoor-outdoor path, as indicated in point 1 of the methodology. Following point 6 of the methodology, the registration between the tracking systems was initially performed at a single point to assess the order of magnitude of drift over time and space. The second part of the experiment details the first part by comparing the same tracking systems and by following an only-outdoor path, executing multiple registrations at predefined time intervals. Specifically, registrations were executed each 20 s during the tracked simulation to assess the drift across several samples, aiming to deduce the minimum necessary frequency of tracking system registration while maintaining "fine-precision" or "high-precision" positional accuracy (Sarlin et al., 2022; Sattler et al., 2017).

Figure 3: View of the operator simulating FM activities using the HoloLens 2 with the RTK add-on.

Results and discussion

The results of the first part of the experiment, as described in the Experiments design and execution subsection, are presented in Figure 4 and Figure 5. Figure 4 displays the 2D layout of the DC3 laboratory and the trajectories recorded by both the GNSS-RTK tracking system (depicted in orange) and the HoloLens 2 (depicted in blue) during the simulation of FM tasks conducted by an operator. The size variation of the markers along the GNSS-RTK-traced path signifies positional accuracy, where larger markers correspond to decreased accuracy.

The registration of the two tracking systems occurred solely at point A, i.e. at the beginning of the route, and only once (Figure 4). Subsequent movements within the laboratory space (zone B) revealed notable inadequacies in the GNSS-RTK tracking system indoors, indicating a substantial decline in accuracy. Further observations highlight zone C, illustrating an analogous scenario to an urban-canyon setting, where the GNSS-RTK system exhibited reduced reliability, potentially favoring the application of the image-based registration system [1]. Upon assessing the external trajectory (zone D), where the RTK system has a centimeter-level accuracy as declared by manufacturers (ublox, 2023), the HoloLens 2 system unreliability outdoors became conspicuous. It noticeably diverged from the RTK data when venturing beyond a certain distance from the registration point, indicating a drift of around 1 m each 45 m traversed (Figure 5). Therefore, the first part of the experiment, while answering RQ.1, demonstrates the need for regular registrations of the tracking systems to contain drift.

In the second part of the experiment, whose results are detailed below and in Figure 6, the outdoor operator route mimics the one of zone D in Figure 4. Along this route, the HoloLens 2 tracking system was registered against the GNSS-RTK at 6 subsequent intervals, spaced 20 s apart, creating 6 subsets of the total path. Drift readings for each subset were registered 1 s apart (Figure 6). These recorded subsets are overlaid in Figure 6, displaying a relatively consistent trend. It is worth noting that only the initial 15 m of each subset are depicted in Figure 6, as values beyond this range prove less significant. In Figure 6, the "Subset4" (light green curve), registering the worst performance, shows that the drift remains below 0.10 m (i.e., "fine-precision" positional accuracy threshold) only within about 2 m of covered distance (around 1.5 s of tracking). Instead, on the overall, the trendline of all subsets (red dashed line) shows that the drift remains below 0.10 m within about 4 m of covered distance. Furthermore, the "Subset4" shows that the drift stays below 0.25 m (i.e., "high-precision" positional accuracy threshold) within around 7 m of covered distance (approximately 6 s of tracking). Instead, on the overall, the trendline of all subsets shows that the drift remains below 0.25 m within around 9 m travelled. This result further answers RQ.1.

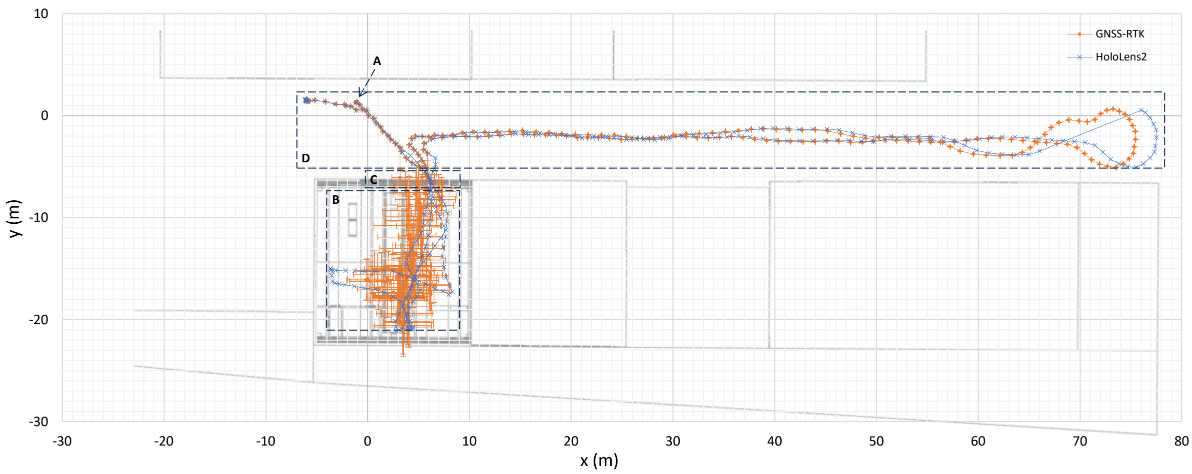

Figure 4: 2D view of the paths travelled by the operator and tracked by the GNSS-RTK (orange) and HoloLens 2 (blue) tracking systems. The grid has a mesh size of 1 m. Smaller orange markers along the GNSS-RTK route indicate higher accuracy of the samples.

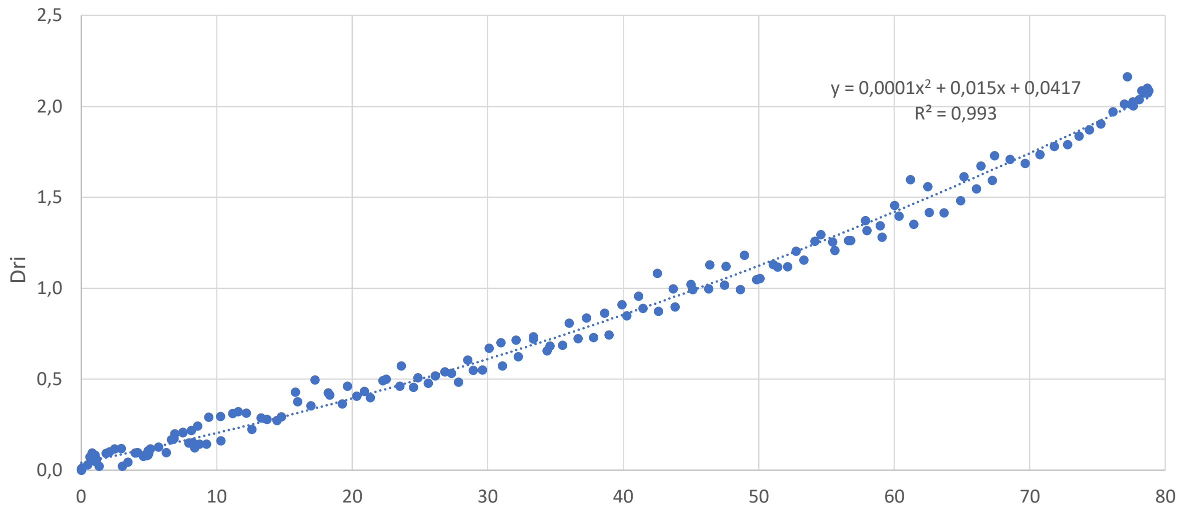

Figure 5: Outdoor assessment of HoloLens 2 drift against GNSS-RTK ground-truth localization (only zone D). The system is spatially registered only once at the beginning of the route.

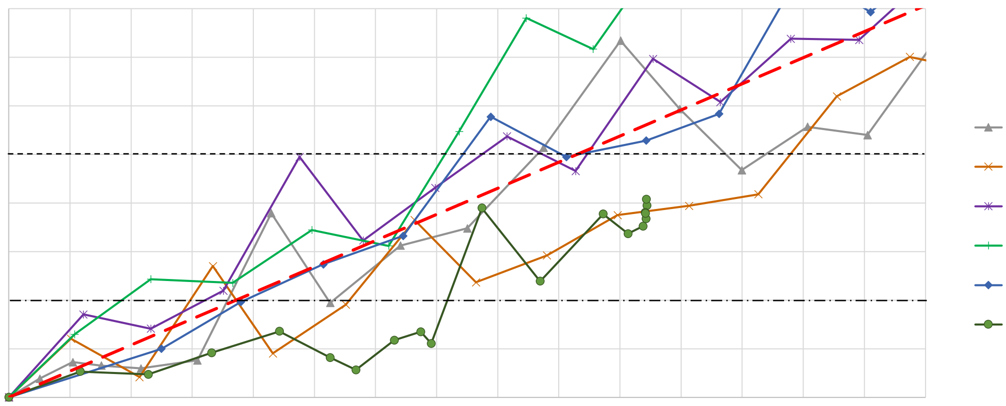

Figure 6: HoloLens 2 drift against GNSS-RTK ground-truth for each subset and trendline (red dashed line), related to the path traversed during the second experiment (only outdoor scenario – zone D). Horizontal dashed and dashed-dotted grey lines represent the "high-precision" and "fine-precision" positional accuracy thresholds at 0.25 m and 0.10 m respectively.

To sum up, for achieving in all outdoor circumstances a "fine-precision" positional accuracy, required for a good AR user experience (Sarlin et al., 2022; Sattler et al., 2017), the results underscore the need of aligning the HoloLens 2 tracking system with the GNSS-RTK approximately every 1.5 s or 2 m of travelled distance. Instead, to ensure the "fine-precision" positional accuracy on the overall, the results underscore the need of aligning the HoloLens 2 tracking system with the GNSS-RTK approximately every 4 m of travelled distance. This result answer RQ.2. It must be noted that, in this study, the RTK time latency was considered and the existing delay between the acquisition of GNSS-RTK samples and those from the HoloLens 2 was compensated.

Conclusions

Despite its immense potential, AR encounters barriers hindering its widespread implementation in real construction processes. One of the primary obstacles lies in the difficulty of aligning and sustaining the stability of holograms in mixed scenarios. The seamless integration of indoor-outdoor AR registration systems is imperative for effective built environment management.

The authors proposed a markerless augmented reality registration system that integrates RTK, IMU technologies, and image comparison based on CNN. Such system was qualitatively tested on a FM use case related to a university campus (Messi et al., 2023). This paper extends preliminary tests conducted on the proposed AR registration system. The aim of this study is quantifying drifts experienced within the different tracking systems embedded in the AR registration engines and determine the optimal registration frequency required for practicality in real FM scenarios. Experiment results have provided insights into the system performance, highlighting its capabilities, limitations, and areas of refinement. Such results can be summarized as follows:

- HoloLens 2 tracking system, as shown by the first part of the experiments, exhibited significant drift outdoors, reaching about 1 m per 45 m traversed

(Figure 4 and Figure 5). This result, while answering RQ.1, confirmed the need of periodic spatial registrations to contain drifts between the tracking systems.

- The second part of the outdoor experiments showed, in the worst subset, drifts below 0.10 m within around 1.5 s or 2 m of travelled distance and below 0.25 m within around 6 s and 7 m traversed (Figure 6). The overall trend of all subsets, instead, shows a drift below 0.10 m within about 4 m and below 0.25 m within about 9 m of travelled distance. These results extend the answer to RQ.1 and highlight the critical need of spatial registration of HoloLens 2 against GNSS-RTK.
- Finally, for achieving in all outdoor circumstances a "fine-precision" positional accuracy, required for a good AR user experience, aligning HoloLens 2 with GNSS-RTK data every 1.5 s or 2 m of travelled distance is crucial. Overall acceptable results can be achieved by aligning HoloLens 2 with GNSS-RTK data every 4 m of travelled distance. These results answer RQ.2.

Future works will focus on the assessment of the drift between image-based and HoloLens 2 tracking systems as explained in point 3, 4 and 7 of the presented methodology (Evaluation method section). Then, data fusion techniques should be applied to combine the different data sources and achieve better results in scenarios served by both the GNSS-RTK and image-based tracking systems.
