Bienvenidxs al archivo del instituto nacional del suelo

La hidrología argentina no se detiene en nuestras fronteras nacionales. Los ríos de Brasil, Bolivia, Uruguay y Paraguay aportan nutrientes a nuestros cursos de agua y suelos. Argentina está enredada en esta red de cuencas y la salud futura de nuestras aguas depende también de la salud del agua de nuestro vecino.

El trabajo del Instituto Nacional del Agua y ACUMAR proporciona información útil sobre cómo restaurar vías fluviales contaminadas. En el INS nos enfocamos en la salud de nuestros suelos, que son fuentes frecuentes de contaminación que luego ingresan a nuestros cursos de agua. De esta forma, contamos con un plan de regeneración integral que limpia el terreno y el agua simultáneamente.

Welcome to the archive of the national soil institute of argentina

Argentine hydrology does not stop at our national borders. The rivers of Brazil, Bolivia, Uruguay and Paraguay provide nutrients to our watercourses and soils. Argentina is entangled within this network of basins and the future health of our waters depends on the health of our neighbor's water, too.

The work of the National Water Institute and ACUMAR provide helpful insight into how to restore polluted waterways. At the INS, we focus on the health of our soils which are frequent sources of pollution that later enter our waterways. In this way, we have a comprehensive regeneration plan that cleans the land and the water simultaneously.

Hemos establecido nodos de producción de suelos en toda la cuenca Matanza-Riachuelo, en un esfuerzo por demostrar el carácter cooperativo imprescindible de la restauración y gestión de residuos ante los grandes desafíos sociales y ecológicos.

Este archivo es una colección de documentos de trabajo que se agregarán y sustraerán periódicamente. todos los contenidos están disponibles para su descarga, para ser difundidos a través de diversas plataformas, tanto digitales como físicas. visítenos en nuestro nuevo protonodo, el baldío en avellaneda.

Para conocer los últimos eventos o aprender más sobre la salud del suelo, consulte nuestro sitio web ins-ar.org

¡Visite el nodo más cercano a usted hoy!

We have established soil production nodes throughout the Matanza-Riachuelo basin, in an effort to demonstrate the essential cooperative nature of the restoration and waste management in the face of great social and ecological challenges.

This archive is a collection of working documents developed during the collaboration between the institute and gunkspace. it will periodically be added to and subtracted from. all of the contents within are available for download, to be disseminated across diverse platforms, both digital and physical.

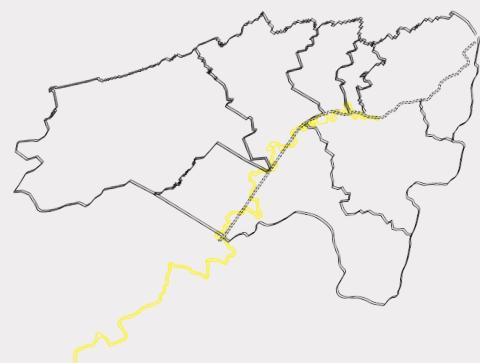

For the latest events or to learn more about soil health check our website ins-ar.org, our new protonode, el baldío, in the avellaneda district of buenos aires. Visit us today!

Then we zoom in to the microbasins of the lower urban basin. First, the Avellaneda microbasin!

LOWER URBAN SUBBASIN

The protonode network of the lower urban basin. There are nine microbasins, each with their own protonode. As often as possible, protonodes reuse existing infrastructure. The urban lower basin was selected for the first subbasin given its proximity to the urban population, increasing its visibility to the public.

* The Avellaneda microbasin has 108 urban blocks. This means there will be 12 superblocks, and thus 12 nodes

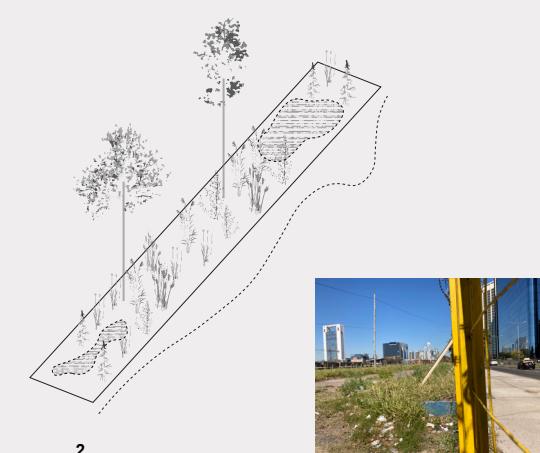

URBAN SUPERBLOCK

Microbasins are composed of superblocks. This is the working scale where urban interventions can be detailed. Like the Superilles in Barcelona, Buenos Aires can arrange itself within a 3x3 block grid. Outside of this grid, circulates traffic and transit. Within this grid circulate resources. There are 3 (interstitial) ecologies that can be identified in a superblock: the riparian buffer, the prairie corridor and the community patch.

It has been revealed that the three ecologies within the average superblock can accommodate up to 5,000m³ of compost annually.

1 (riparian) buffer

"Riparian zones provide many ecological functions and services as biological corridors and buffer zones to retain pollutants that may enter from urban runoff while mitigating flooding" (Gomez et al., 2020).

2 (prairie) corridor

"Prairie strips help reduce nitrous oxide emissions by soaking up nitrogen fertilizer that runs off of adjacent cropland. They also can store carbon in soil... and reduce erosion and nutrient loss from soil and support birds and insects. Prairie strips are among the least expensive conservation practices available to farmers" (Moore, 2021).

3 (community) patch

provide open space in city centers which serve as opportunities for education, recreation and local food sovereignty

NODE MR.01.AV.001

Nodes inhabit the 3 interstitial ecologies. Each superblock has at least one node. They are primarily responsible for composting the organic waste of residents within the superblock. However, they also serve as community centers and green space. A node can be a library, a playground, a theatre, a cafe... they are infinite.

This depicts the first protonode of the Avellaneda microbasin, El Baldío, or “the wasteland,” embedded within a restored riparian buffer along the main channel of the Matanza-Riachuelo.

- 1 Evapotranspiration from vegetation cools surrounds
- 2 Interior vegetation moderates air quality and moisture
- 3 Double facade
- 4 Warm air extracted thru solar chimney
- 5 Soil critters transform organic waste into compost
- 6 Compost applied to vegetation
- 7 Variety of plant roots increase soil porosity and stabilize riverbank, reducing erosion

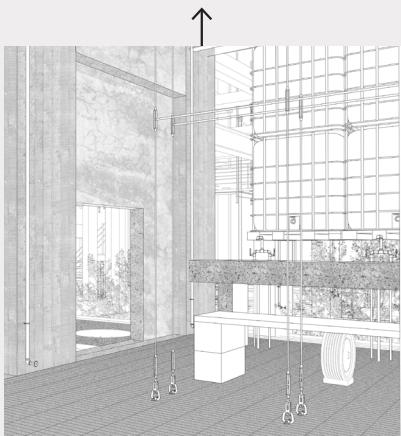

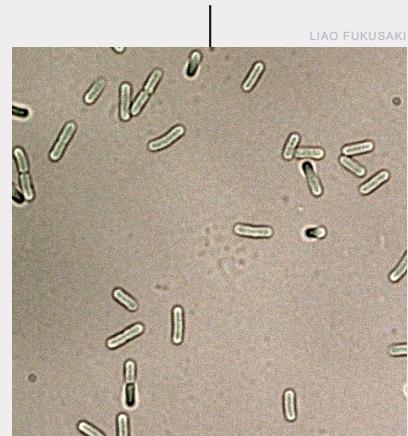

3
Fermented mixture delivered to micronodes

4
And distributed to residents of each superblock

2
It is processed at the protonode into a fermentation mixture

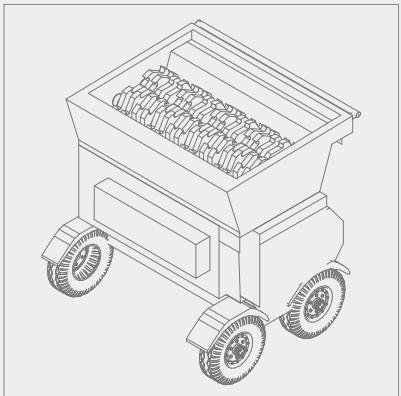

5
Organic waste is collected at home, fermented mix applied, decomposition begins

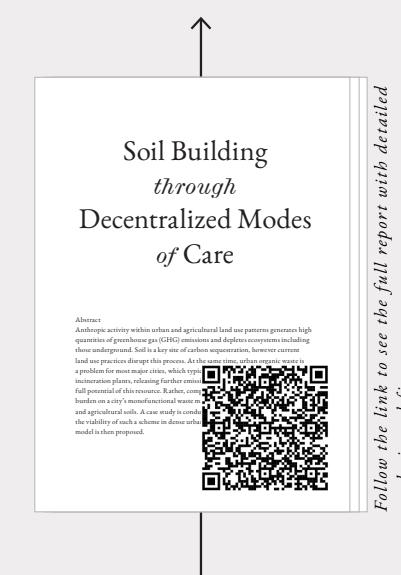

1
Fungal matter (mycelium) is harvested from the three ecologies

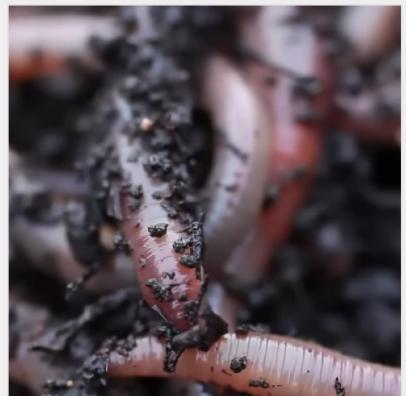

**compost,
or,
how
junk
becomes
gunk**

7
After 10 days, waste is macerated, reducing particle size, increasing surface area

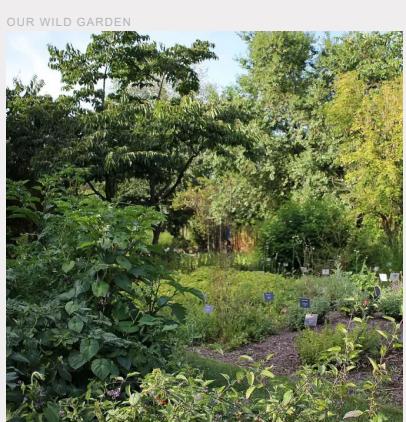

6
Fermented waste is deposited at node

8
Macerated fermented waste is placed into an underground vermicompost chamber

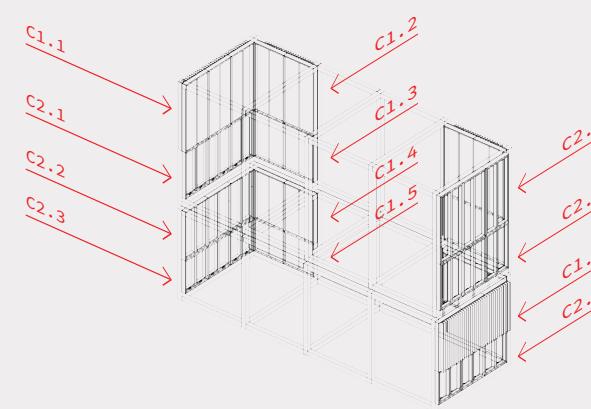

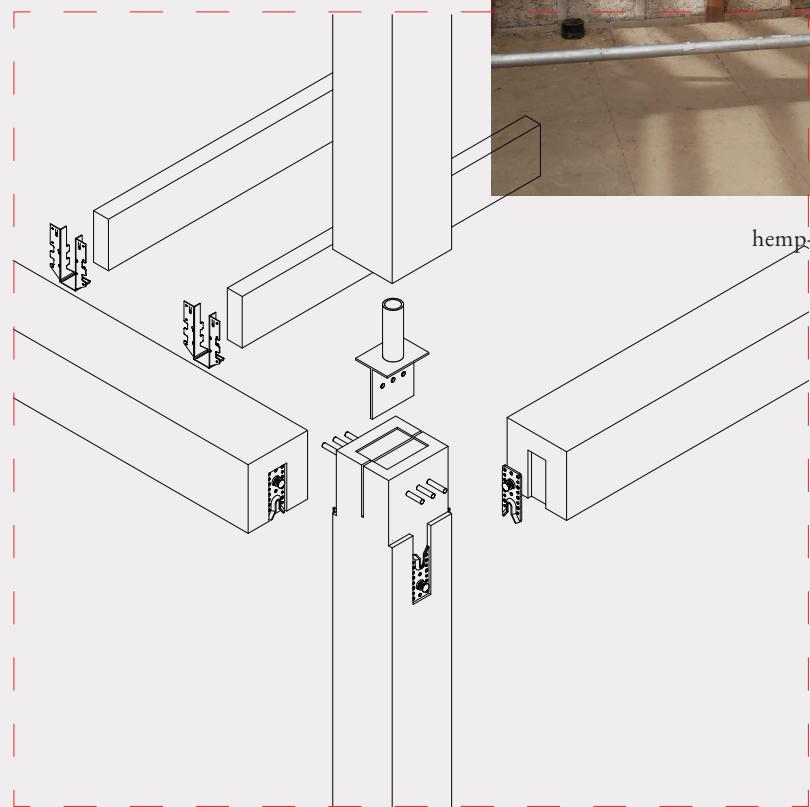

9
10-14 days later, waste has been transformed into compost

10
Compost is applied locally to vegetation within the three ecologies

found and grown components

Grown components are wood framed cassettes filled in with bio-based insulation grown in the three ecologies. For El Baldo, these cassettes are dimensioned to slot between the existing concrete structure for ease of assembly and demounting.

The INS begins an ad campaign that communicates the new waste management system to urban residents

NODE MR.01.AV.005

NODE MR.01.AV.006

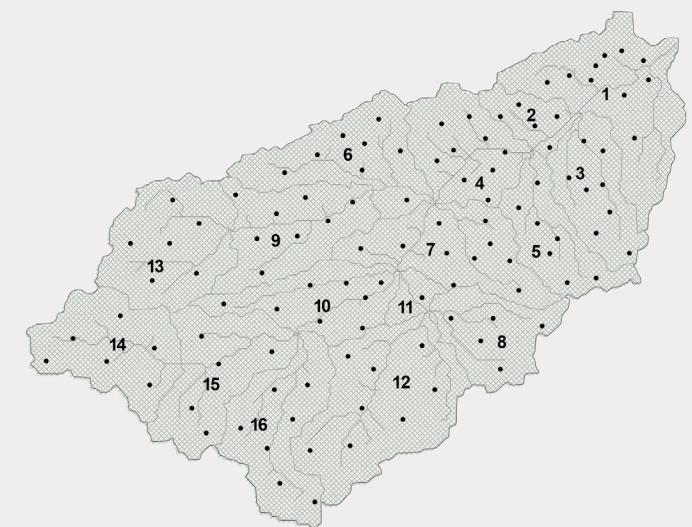

NODE MR.01.AV.011

NODE MR.01.AV.003

The eco-hydrological network progresses with more connections throughout the Avellaneda microbasin

NETWORK!

The network of protonodes throughout the 16 subbasins of the Matanza-Riachuelo basin. Each protonode corresponds to its locale: whether it is located in agricultural or urban areas. Urban nodes are meant to attract residents to the composting program and to aestheticize regeneration in an age of collapse. Agricultural nodes are responsible for communicating the method of agroforestry practices to farmers and food producers so that farms in the region can adopt such methods.
