

Banking on the city for secondary resources that can release the pressure on natural environment and progress towards Environmental Sustainable urban integrated systems

CONTEXT

Urbanisation in the developing countries, especially in India is growing at an unprecedented rate. The metropolitan cities are expanding beyond their hinterlands with increasing urban population and affluence. The increasing demand for resources is creating pressure on the environment. The linear process of extraction of resources is affecting the environment. Due to India's sustained economic growth, increasing living standards and changing production and consumption patterns, there is an increase in the amount of waste that is being generated. This can be attributed to the linear approach towards resource consumption, usage and disposal. This thesis analysed this problem in the city of Visakhapatnam, India which is already facing the challenges of environmental degredation. In this thesis, the resource flows of food and water have been analysed as they are the major share of waste that is being produced. The resource flows are analysed from their source to sink and the streams of waste that is being produced in each stage causing environmental damage. The thesis has proposed the transition into circular metabolism of these two resource flows to better the environmental sustainability.

Problem Statement:

The growing affluence and linear model of resource consumption, production and disposal are causing environmental damage in the city of Visakhapatanam. However, the city's approach towards increasing volumes of waste is limited to optimizing the existing waste disposal systems and develop end of pipe solutions, though there is a potential in utilizing the waste streams as secondary resources and promote thoughtful consumption. This is due to the lack of awareness about the benefits of resource reuse for both the citizens and administrative sectors.

Hence, there is an urgent need to evolve this linear metabolic process into a circular process. Implementing the new system to an already existing system is the main challenge. It has to be implemented at multiple scales, with both top-down and bottom-up strategies.

Research Question:

using resources efficiently and reusing the waste streams as.... secondary resources by circular principles

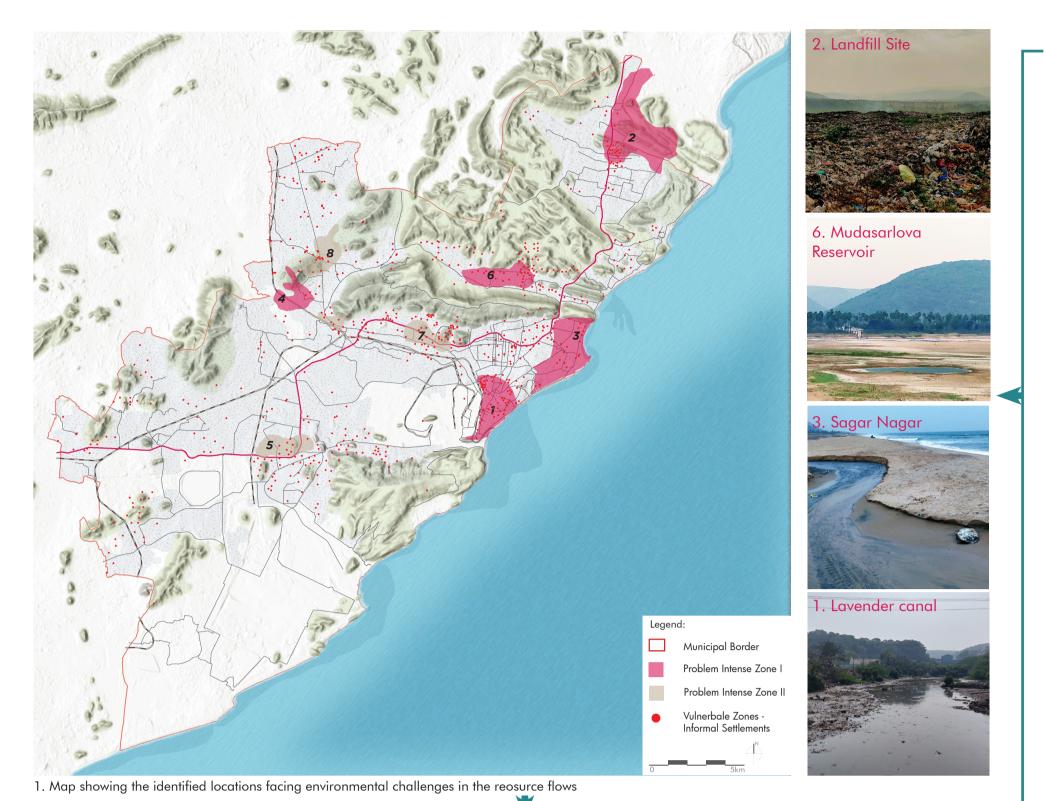

integrative approach of governance, socio-.... ecological systems and socio technical sytems

How to integrate resource management into urban planning by developing local scale spatial strategies for an environmentally sustainable Visakhapatnam?

> "meeting the resource and services needs of current and future generations without compromising the health of the ecosystems that provide them," (Morelli, John (2011))

In 2050, The city of Visakhapatnam will be known as "Local -Adaptable City", owing to its long term vision of cohesive food and water resource management systems. The looping within existing infrastructure, mesoscale localised strategies for water management and the network of organic waste compost centers across the city are the key steps for the transformation. Reinforcing the blue and green infrastructure for regenerative purposes translates into the enhancement of the local living quality. The proposed circular solutions not only improve the ecological systems in the city but also bring in more economic and social welfare opportunities. Apart from the changing policies and subsidies by the ULB, the change in consumer attitude and engagement of local actors/institutions in the delivery of secondary resources, infrastructure and services will increase local autonomy. Thus, the city is a hub for eco-innovative solutions in the food and water resource cycles. The integrated planning system is employed to reach these goals.

ANALYSIS

FOOD FLOWS

WATER FLOWS

Depleting sources of water

Excessive usage of fertilisers

Waste from processing and storage

Pollution of surface water

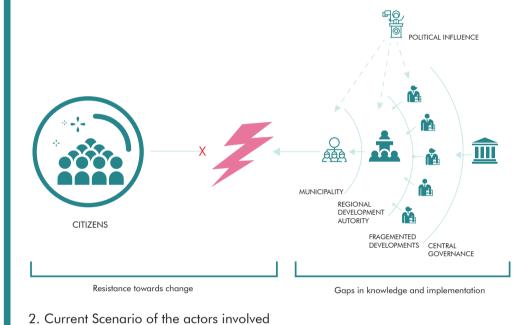

Waste from households -1.2kg/day/household

Decreasing underground water levels

CO2 and methane emissions from waste transportation and incineration respectively

Lack of sewage connections and under capacity STP, discharge of wastewater into natural water sources

The above flow chart represents the findings of the resource flow analysis of food and water from pre consumption phase i.e., production (source), processing, trade/distribution and retail to post consumption phase of consumption. waste collection and waste treatment. The actor analysis during the field trip has helped in identifying the gaps and their effects on the flows. The diagram below represents the current scenario of the

The vision goals are based on three main focus points.

i) Governance ii) Consumer Behavior iii) Technology

Solutions for the pilot cases are proposed in integration with these focus

DESIGN

GOVERNANCE Develop regulatory frameworks for CE, encourage in sharing the knowledge and support the actors at all the levels of governace

CONSUMER BEHAVIOR

Change in attitude towards utilisation of resources and the waste generated considering the different set of actors involved from

source to sink

TECHNOLOGY Enhancing the existing

technology to a broader set of actors as well as proposing new localised ecoinnovative solutions.

LOCAL CITY——

Local city is the city which has its resources localised. This city focuses on building decentralised systems and the circular flows in local/micro scale

Location: Sagar Nagar

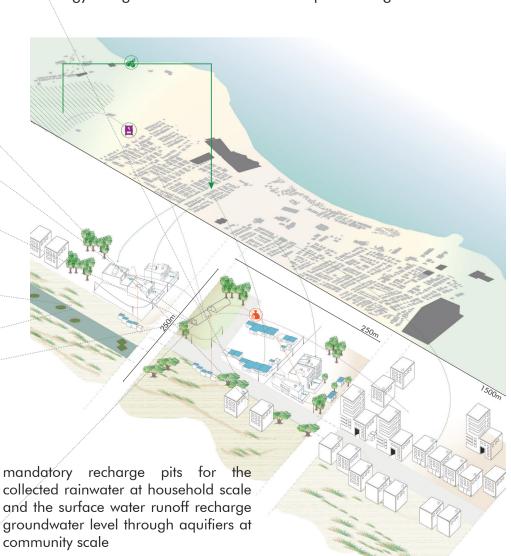

Challenges: Pollution of natural sources of water due to discharge of wastewater because of lack of infrastructure for drinking water supply and wastewater treatment

Proposals: Solutions are proposed on three points:

i) Policy/guidelines: Rules and Regulations developed at the scale of Urbal Local Body for implementing decentralised solutions in the city

ii) Consumer Behavior: Responsible consumption and change in attitude towards waste and utilisation of recycled materials

iii) Technology: Implementation of decentralised wastewater treatment at the scale of block/neighborhood; Mandatory rain water harvesting at both household and community scale; recharge of groundwater through aquifiers; community scale organic compost pits; food waste prevention and purification of polluted water streams with floating wetlands technology. Integration of local actors in implementing the solutions

Research group: Urban Metabolism Mentors: Alexander Wandl, Diego Sepulveda

-LOOPING CITY

Looping city functions as a centralised system. This city focuses on looping the resource flows in large meso/macro scale infrastrcuture.

Location: Lavender Canal

Challenges: Pollution due to discharge of untreated wastewater into the canal

Proposals: Solutions are proposed on three points: i) Policy/guidelines: No discharge of wastewater into surface water

towards waste and utilisation of recycled materials

streams; mandatory segregation of waste ii) Consumer Behavior: Responsible consumption and change in attitude

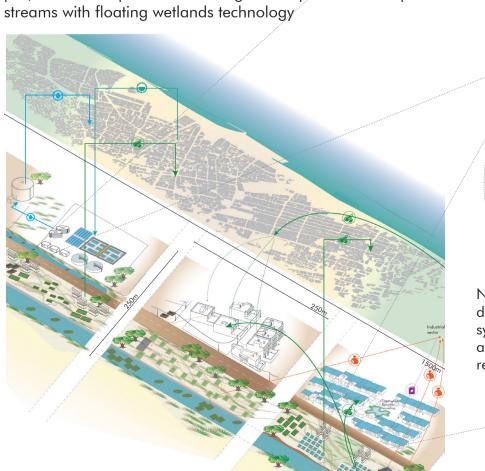

iii) Technology: Upgradation of existing sewage treatment plant and connecting to water distribution center post teritiary treatment; refurbishing the canal and repurposing the open spaces along the canal into regenerative landscapes and tourist attractions with eco-innovaive

solutions; local actor participation in the development of the canal and

vertical integration of all the actors; community scale organic compost pits; food waste prevention strategies and purification of polluted water
