## Abstract

In this study, the gas-liquid membrane contactor was considered for regeneration of the room-temperature ionic liquids (RTIL) that can be used as physical solvents for carbon dioxide capture process at elevated pressures. Poly[1-(trimethylsilyl)-1-propyne] (PTMSP) was selected as a membrane material due to its high mass transport characteristics and good mechanical properties. Nine different RTILs, such as [Emim][DCA], [Emim][BF<sub>4</sub>], [Emim][DEP], [Bmim][BF<sub>4</sub>], [Bmim][Tf<sub>2</sub>N], [Hmim][TCB], [P66614][DCA], [P66614][Br] and [P66614][Phos], were used to evaluate the solvent-membrane compatibility. The long-term sorption tests (40+ days) revealed that the solvent-membrane interaction is mainly determined by the liquid surface tension regardless of viscosity and molecular size of RTILs. For instance, [Emim][BF<sub>4</sub>] and [Emim][DCA], having the surface tension of 60.3 and 54.0 mN/m, demonstrated a very low affinity to the bulk material of PTMSP (sorption as low as 0.02 g/g; no swelling); while for the next ionic liquid [Bmim][BF<sub>4</sub>] with surface tension of 44.4 mN/m, the sorption and swelling of PTMSP was 0.79 g/g and 21%, respectively. The long-term RTIL permeation test ( $\Delta p=40$  bar,  $T=50^{\circ}\text{C}$ ,  $t>400$  hours) confirmed that there is no hydrodynamic flow through PTMSP for [Emim][DCA] and [Emim][BF<sub>4</sub>]. The concept of CO<sub>2</sub> stripping from RTIL with the membrane contactor by the pressure ( $\Delta p=40$  bar) and temperature ( $\Delta T=20^{\circ}\text{C}$ ) swing was proofed by using PTMSP membrane and [Emim][BF<sub>4</sub>]. The overall mass transfer coefficient value was equal to  $(1.6-3.8) \cdot 10^{-3}$  cm/s with respect to liquid flow rate. By using the resistance-in-series model, it was shown that the membrane resistance contribution to the gas transfer was estimated to be approximately 8%.

**Keywords:** membrane contactor, room-temperature ionic liquid, PTMSP, carbon dioxide, stripping

## 1. Introduction

CO<sub>2</sub> stripping (desorption) from different absorbents plays a significant role in the absorption–desorption process to remove acid gases such as CO<sub>2</sub> from gas streams. An important emerging application of gas-liquid membrane contactors is focused on the regeneration of liquid CO<sub>2</sub> absorbents via stripping of dissolved CO<sub>2</sub> through the membrane (Zhao et al., 2016; Bazhenov and Lyubimova, 2016). Within this process transfer of CO<sub>2</sub> from the rich solvent to the gas phase is occurred, while the lean (regenerated) solvent is recycled for further absorption process.

A commonly used membrane contactors are the systems in which the porous membranes (pore size 0.1-0.3 μm) act as nonselective barriers to separate two phases. The hollow fiber membranes based on polytetrafluoroethylene (PTFE) (Khaisri et al., 2011; Ghadiri et al., 2013), polyvinylidene fluoride (PVDF) (Mansourizadeh and Ismail, 2011; Rahbari-Sisakht et al., 2013a), polysulfone (Rahbari-Sisakht et al., 2013b) were used for CO<sub>2</sub> stripping processes.

An important role in the both membrane CO<sub>2</sub> stripping and absorption plays a proper selection of liquid absorbent. It should possess high surface tension and negligible vapor pressure combined with high CO<sub>2</sub> sorption capacity. Room-temperature ionic liquids (RTILs), i.e. organic salts with melting temperatures less than 100°C, are among the best candidates that meet the stated criteria (Ramdin et al., 2012; Dai et al., 2016a).

A great variety of available organic/inorganic cations and anions allows to design RTILs with unique properties, which are widely studied as solvents, media or additives in catalysis (Hallett and Welton, 2011; Andreeva et al., 2007), electrochemical applications (MacFarlane et al., 2007), analytical (Sun and Armstrong, 2010) and biochemistry (Jain et al., 2005), membrane gas separation processes (Dai et al., 2016a; Akhmetshina et al., 2017) etc. Since RTILs might also possess relatively high CO<sub>2</sub> solubility and noticeable solubility selectivity over other gases, they were proposed for carbon dioxide capture and stripping as an alternative to conventional solvents due extremely low volatility, good thermal stability, lower heat duty at desorption stage as a result of physical bonding of CO<sub>2</sub> molecules, low corrosiveness and biodegradability (Ramdin et al., 2012, 2014; Lei et al., 2014; Karadas et al., 2010; Bazhenov et al. 2014). RTILs demonstrate typical behavior of a physical solvent in that the solubility of gases increases with gas pressure according to Henry's Law typically for gas pressures up to 10 bar (Dai et al., 2016a), thus the increasing of carbon dioxide partial pressure decreases energy requirements for RTILs as physical CO<sub>2</sub> solvents (Karadas et al., 2010). This results in greater potentials of RTILs in high-pressure applications (e.g. pre-combustion CO<sub>2</sub> capture or natural gas sweetening).

Imidazolium-based RTILs 1-ethyl-3-methylimidazolium ethylsulfate ([Emim][EtSO<sub>4</sub>]) and 1-ethyl-3-methylimidazolium acetate ([Emim][Ac]) were already used for the CO<sub>2</sub> capture in the

1 gas-liquid contactors with porous hollow fiber membranes made from hydrophobic polypropylene  
2 (PP) or polysulfone (Albo et al., 2011; Gómez-Coma et al., 2014, 2016).

3 Sirkar et al. (2013, 2014) were the first who studied the applicability of RTILs with  
4 membrane contactors for high pressure and temperature pre-combustion CO<sub>2</sub> capture from syngas.  
5 They used porous ceramic tubes with silane coating and porous polyether ether ketone (PEEK)  
6 hollow fibers. Similarly, Dai and Deng (2016) and Dai et al. (2016b) applied porous glass  
7 membranes and butyl-3- methylimidazolium tricyanomethanide ([Bmim][TCM]) to absorb CO<sub>2</sub>  
8 at high temperatures (up to 80°C) and pressures (up to 20 bar).

9 The main problem in the operation of gas-liquid membrane contactors is the wetting of  
10 membrane pores, which leads to substantial increase of mass transfer resistance (Albo et al., 2011;  
11 Dai and Deng, 2016; Dai et al., 2016c). Wetting risk imposes restrictions on the pressure difference  
12 between the liquid and gas side of membrane contactor (typically of 0.2-0.3 bar) (Mosadegh-  
13 Sedghi et al., 2014). There are two ways to eliminate wetting effect and prevent any penetration  
14 of the solvent into the organic polymer membrane. The first method is to use a composite hollow  
15 fiber or an asymmetric skinned membrane. The alternative is to use a dense, self-standing  
16 polymeric membrane, highly permeable towards CO<sub>2</sub> and impermeable towards the solvent.

17 A thin selective layer coated onto a porous polymer support reduces the membrane  
18 permeability. However, the permeability loss can be compensated by the increasing the driving  
19 force with elevating the trans-membrane pressure. Recently, Nguyen et al. (2011) tested composite  
20 hollow fibers with a thin dense layer, based on a highly permeable glassy polymers (poly[1-  
21 (trimethylsilyl)-1-propyne] (PTMSP) and Teflon AF 2400), coated on a porous PP support for the  
22 absorption of CO<sub>2</sub> in conventional amine solutions. It has been found that the membrane with  
23 Teflon-AF thin layer shows the capture ratio and the overall mass transfer coefficient at a level of  
24 porous PP membrane. Dibrov et al. (2014) found that the thin film composite membrane with  
25 PTMSP layers on a metal-ceramic support demonstrated stable CO<sub>2</sub> flux during 100 h of stripping  
26 process from amine solution at elevated pressure and temperature (30 bar, 100 °C). Scholes et al.  
27 (2015) studied the CO<sub>2</sub> stripping from monoethanolamine solution using three composite  
28 membranes with a selective layer of PTMSP, PIM-1 and Teflon AF1600 on a porous PP support.  
29 It is found that over 90% of the overall resistance falls on the liquid boundary layer. Recently, thin  
30 film composite membrane approach was used for membrane absorption with RTIL solvent: Dai et  
31 al. (2016c) demonstrated the potential of applying the PP hollow fibers with dense Teflon AF 2400  
32 layer for CO<sub>2</sub> capture at elevated temperatures (80°C) and pressures (20 bar) with [Bmim][TCM]  
33 as absorbent. The composite membrane contactor showed better long-term stability compared with  
34 the porous PTFE membrane contactor.

1 Integrally dense membrane contactor, i.e. the contactor based on non-porous self-standing  
2 membranes, is little used for CO<sub>2</sub> absorption/stripping. In cited article (Nguyen et al., 2011), a  
3 module based on self-standing polydimethylsiloxane (PDMS) hollow fibers were also tested. It  
4 has been experimentally found that these fibers showed lower performances in comparison to the  
5 porous and composite fibers. Nevertheless, both laboratory and pilot plant measurements on the  
6 separation of CO<sub>2</sub> from flue gas by Scholes et al. (2014) reports that the contactor based on non-  
7 porous PDMS does not experience wetting, yet the overall mass transfer coefficient two orders of  
8 magnitude less than the porous PP contactor.

9 Authors of papers (Dibrov et al., 2014; Trusov et al., 2011; Bazhenov et al., 2012; Shutova  
10 et al., 2014; Shalygin et al., 2008; Beggel et al. 2010; Volkov et al. 2015) examined the potential  
11 of dense membrane contactors based on disubstituted polyacetylenes, polynorbornene,  
12 polyvinyltrimethylsilane (PVTMS) for CO<sub>2</sub> stripping and absorption with various both chemical  
13 and physical absorbents. It was demonstrated that PTMSP, a polymer with the highest CO<sub>2</sub>  
14 permeability, is long-term stable and impermeable under elevated temperatures and pressures for  
15 the hydrodynamic flux of water (trans-membrane pressure  $\Delta p$  up to 100 bar,  $T$  up to 100°C)  
16 (Trusov et al., 2011; Grekhov et al., 2012), aqueous amine solvents ( $\Delta p$  up to 40 bar,  $T$  up to  
17 100°C) (Trusov et al., 2011; Bazhenov et al., 2012). Moreover, this material turned out to be a  
18 barrier for RTIL 1-butyl-3-methylimidazolium tetrafluoroborate [Bmim][BF<sub>4</sub>] ( $\Delta p=40$  bar,  $T = 30$   
19 and 100°C) (Volkov et al. 2013). Therefore PTMSP can be considered as promising material for  
20 CO<sub>2</sub> stripping from RTIL as a solvent.

21 In the present work, we focused on the CO<sub>2</sub> stripping process from RTIL using integrally  
22 dense membrane contactor based on PTMSP membrane. It is known that RTILs may gradually  
23 dissolve some polymeric membranes. A careful choice of the RTIL as the solvent for CO<sub>2</sub> is  
24 therefore crucial for an efficient stripping process.

25 The first objective of this study is swelling tests among several commercially available  
26 RTILs in order to identify the liquid with lowest thermodynamic affinity to the polymer, i.e. with  
27 the lowest swelling of the polymeric membranes. The second one is to investigate the CO<sub>2</sub>  
28 stripping flux and efficiency in flat-sheet dense membrane contactor based on PTMSP and to  
29 estimate the relative contribution of the membrane resistance to the overall mass-transfer process.

## 31 **2. Experimental part**

### 32 *2.1. Ionic liquids*

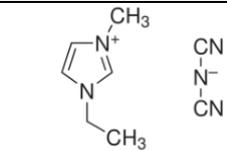

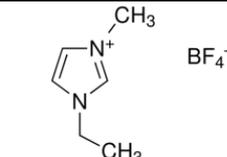

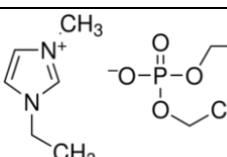

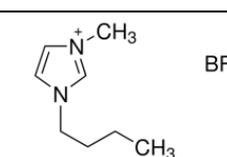

33 Eight different room-temperature ionic liquids with a varied characteristics were purchased  
34 from Sigma Aldrich Chemie GmbH: 1-Ethyl-3-methylimidazolium dicyanamide ([Emim] [DCA],

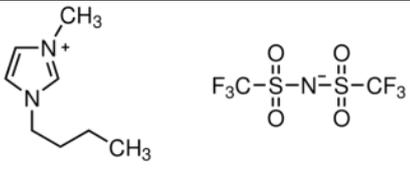

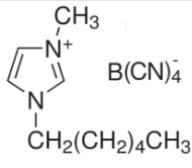

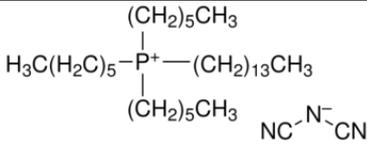

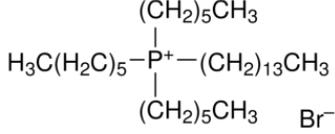

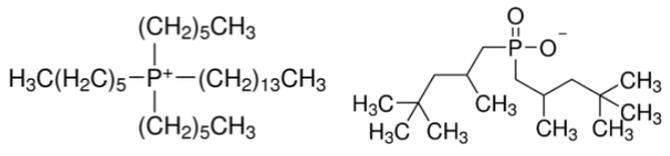

1 Aldrich #713384), 1-Ethyl-3-methylimidazolium tetrafluoroborate ([Emim][BF<sub>4</sub>], Aldrich  
 2 #711721), 1-Ethyl-3-methylimidazolium diethyl phosphate ([Emim][DEP], Aldrich #713392), 1-  
 3 Butyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ([Bmim][Tf<sub>2</sub>N], Aldrich  
 4 #711713), 1-Butyl-3-methylimidazolium tetrafluoroborate ([Bmim][BF<sub>4</sub>], Aldrich #711748),  
 5 trihexyltetradecylphosphonium dicyanamide ([P66614][DCA], Aldrich # 56776),  
 6 trihexyltetradecylphosphonium bromide ([P66614][Br], Aldrich # 96662),  
 7 trihexyltetradecylphosphonium bis(2,4,4-trimethylpentyl)phosphinate ([P66614][Phos], Aldrich #  
 8 28612). The 1-hexyl-3-methylimidazolium tetracyanoborate ([Hmim][TCB]) was provided by  
 9 Merck KgaA, Germany. All the RTILs were used without further chemical purification. The only  
 10 precaution taken was the dry storage under vacuum and elevated temperature (80°C) conditions to  
 11 avoid any water uptake by the ionic liquid. Water content of used RTILs, after drying, was  
 12 measured by Karl Fischer titration (Metrohm 756 KF Coulometer) and did not exceed 1300 ppm.  
 13 The chemical structures and some properties of selected RTILs are listed in Table 1.

14

15 **Table 1**

16 Chemical structures and molar weights of studied ionic liquids.

Name	Chemical structure	MW, g/mole
[Emim][DCA]		177.2
[Emim][BF <sub>4</sub> ]		198.0
[Emim][DEP]		264.2
[Bmim][BF <sub>4</sub> ]		226.0

[Bmim][Tf <sub>2</sub> N]		419.4
[Hmim][TCB]		282.1
[P66614][DCA]		549.9
[P66614][Br]		563.8
[P66614][Phos]		773.3

1

## 2 2.2. Membrane preparation

3 Poly[1-(trimethylsilyl)-1-propyne] (PTMSP) was synthesized by polymerization of 1-  
4 (trimethylsilyl)-1-propyne in a toluene solution using TaCl<sub>5</sub>, with cocatalyst triisobutylaluminum  
5 (TIBA), as the catalyst (Khotimsky et al., 2003). The dense membranes (films) with required  
6 thickness were cast from solution with a polymer concentration of 0.5 wt.% (solvent: chloroform)  
7 onto a commercial cellophane. Then the cast film was covered with a Petri dish and left for slow  
8 evaporation for several days, followed by drying in the oven at 40°C until a constant sample weight  
9 was obtained. Further treatment of all membranes was according to the standard protocol of  
10 membrane preparation (Volkov et al., 2002). The membrane thickness was measured by a  
11 Mitutoyo® 273 Quick Step electronic micrometer.

12

## 13 2.3. Sorption and swelling experiments

14 Dense membrane samples with thicknesses of 60-75 μm were used for the sorption and  
15 swelling tests in RTILs. The dry preweighed rectangular polymer films (25×40 mm) were  
16 immersed and soaked in chosen RTILs at ambient temperature (22±2°C) within sealed bottles.  
17 Since the diffusivity of viscous RTILs in the polymer films might be a very slow process, the  
18 sorption/swelling experiments were carried out for at least 40 days to ensure reaching the

1 equilibrium. The samples were periodically removed from the RTILs, blotted with filter paper for  
2 the removal of the liquid excess from the surface and weighed in stoppered bottles to obtain a  
3 constant weight. After the experiments, the dimensions and weight of cleaned films were  
4 measured.

5 The sorption value has been expressed as a relative weight increase,  $\Sigma = (m - m_0)/m_0$  where  $m$  is  
6 the polymer film weight after soaking and removal of RTIL excess from the surface,  $m_0$  is the  
7 weight of the dry sample. The sorption value was measured with an experimental error of about  
8 1% using a precision microbalance which allows the weighing of polymer samples with an  
9 accuracy of about 30  $\mu\text{g}$ .

10 The polymer volumetric swelling degree ( $SD$ ) in the RTILs was calculated as  
11  $SD = (Al/A_0l_0) - 1$ , where  $l$  and  $A$  are the thickness and surface area of the polymer film in the  
12 solvent, and  $l_0$  and  $A_0$  are counterparts for the dry film. The swelling degree was measured with an  
13 experimental error of about 5%.

14

#### 15 2.4. FTIR spectroscopy

16 The PTMSP films soaked in selected RTILs were studied with FTIR spectroscopy. FTIR  
17 spectrometer IFS-66 v/s vacuum Bruker was used to collect spectra of dry polymeric films with a  
18 thickness of 8-10  $\mu\text{m}$  and ionic liquids in transmission mode in the range of 400–4000  $\text{cm}^{-1}$  (30  
19 scans, resolution 2  $\text{cm}^{-1}$ ). The ionic liquid was placed between two optical silica glasses. The  
20 spectra of the soaked polymeric films containing ionic liquids were collected in the reflection mode  
21 (ATR) in the range of 600-4000  $\text{cm}^{-1}$  by using IR microscope HYPERION-200 (150 scans,  
22 resolution 2  $\text{cm}^{-1}$ , ZnSe crystal).

23

#### 24 2.5. $\text{CO}_2$ and RTILs permeation testing

25  $\text{CO}_2$  permeability through PTMSP was determined by the volumetric method (Dibrov et al.,  
26 2014) at 30°C as  $J \cdot l / \Delta p$  where  $J$  denotes the gas flux per unit surface area of the membrane, per  
27 unit time,  $\Delta p$  – transmembrane pressure,  $l$  – membrane thickness. Hydrodynamic permeation  
28 (leakage) of RTILs across the membrane was studied at a trans-membrane pressure of 40 bar and  
29 temperature of 50°C for at least 400 hours. The experiments were performed according to the  
30 procedure described earlier (Trusov et al., 2011): the flat-sheet sample of the tested membrane was  
31 placed in a dome-shaped dead-end filtration cell; then, the upper compartment of the cell was  
32 partially filled with the selected RTIL and pressurized with carbon dioxide. A porous stainless

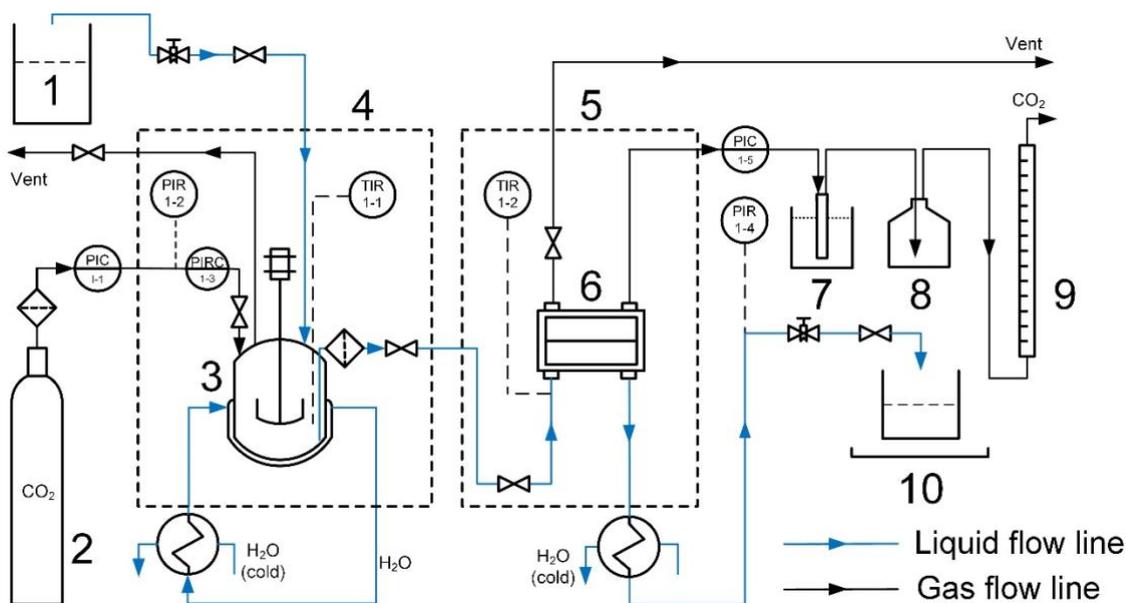

1 steel support was used to avoid damage to the membrane due to the high pressure. Both cell and  
2 permeate collectors were kept in the thermal chamber.

3

#### 4 2.6. CO<sub>2</sub> stripping from RTIL in membrane contactor

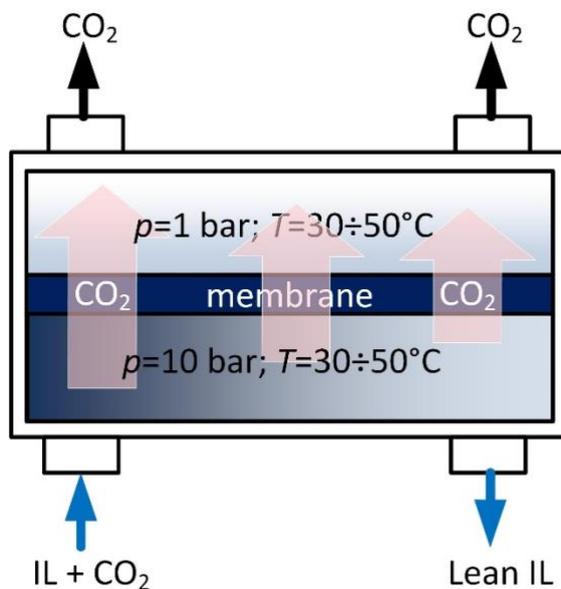

5 Stripping of CO<sub>2</sub> from the ionic liquid [Emim][BF<sub>4</sub>] in a membrane contactor based on  
6 PTMSP dense membranes was carried out with the lab-scale high pressure/temperature membrane  
7 gas stripping set-up (Fig. 1) described previously (Shutova et al., 2014). The RTIL was initially  
8 saturated with carbon dioxide at a pressure of 10 bar. For this purpose, the absorber 3 was filled  
9 up with RTIL from the initial tank 1. The absorber 3 is a high-pressure temperature-controlled  
10 vessel equipped with a propeller stirrer and encased in thermal chamber 4. CO<sub>2</sub> entered the  
11 absorber 3 from the gas cylinder 2 and dissolved in the RTIL with constant agitation rate under  
12 the pressure 10 bar (controlled with Bronkhorst® precise pressure sensors) and temperature 30°C  
13 during at least 4 h to reach the equilibrium. Then, the saturated RTIL under the same pressure was  
14 supplied into the slit rectangular channel formed between the flat-sheet membrane and the shell  
15 within the membrane contactor 6, which is schematically shown on Fig.2. The height of the slit  
16 channel is equal to 0.01 cm. The active membrane area in the contactor is 16 cm<sup>2</sup>; the membrane  
17 thickness is 21±1 μm. A porous stainless steel support with negligible gas flow resistance was  
18 used in the permeate collector to prevent membrane damage. The membrane contactor is encased  
19 in thermal chamber 5 to control the process temperature. A stainless steel pipe (Swagelok, OD =  
20 3 mm) with a length of about 1.5 m was installed in the thermal chamber 5, just before the  
21 membrane contactor 6, as a heat exchanger.

22

23

1 **Fig. 1.** Membrane gas stripping setup: 1 – initial ionic liquid tank; 2 – CO<sub>2</sub> gas cylinder; 3 – absorber; 4, 5 – thermal  
 2 chambers; 6 – high-pressure flat-sheet gas-liquid membrane contactor; 7 – cold trap; 8 – safety flask; 9 – digital gas  
 3 flow meter; 10 – degassed ionic liquid sampler and microbalance.  
 4

5  
 6 **Fig. 2.** Scheme of high-pressure flat-sheet gas-liquid membrane contactor.  
 7

8 During the stripping process, CO<sub>2</sub> was desorbing from the RTIL through the membrane to  
 9 the permeate collector of the contactor which is at atmospheric pressure. During the experimental  
 10 run, the CO<sub>2</sub> flow was leaving the permeate compartment of the contactor, and its flow rate was  
 11 directly measured with the flow-meter 9. The RTIL flow rate in the contactor was adjusted with a  
 12 needle valve at the outgoing liquid flow line. The liquid flow rate was estimated through the  
 13 weighing of the degassed ionic liquid collected in the sampler 10 with an electronic microbalance  
 14 followed by dividing this value by the RTIL density. During the experiments, the desorbed CO<sub>2</sub>  
 15 flow was measured as a function of RTIL flow-rate. It should be noticed that during the whole  
 16 operation of gas-liquid membrane contactor, no droplets of RTIL was observed in the gas collector  
 17 of the contactor.  
 18

### 19 **3. Mass transfer in membrane contactor**

20 The key characteristics of gas mass transfer are the stripping flux and the stripping  
 21 efficiency. The latter parameter is defined as

$$\eta = 1 - C_L^{\text{out}} / C_L^{\text{in}} \quad (1)$$

1 where  $C_L^{\text{out}}$  and  $C_L^{\text{in}}$  are the feed liquid phase CO<sub>2</sub> concentrations at outlet and inlet of the  
 2 membrane contactor, respectively. The CO<sub>2</sub> stripping flux  $J_{\text{CO}_2}$  is equal to the mass loss of the gas  
 3 under liquid flow through the slit channel per membrane area  $A$ , per unit time:

$$J = \frac{Q_L}{A} (C_L^{\text{in}} - C_L^{\text{out}}) = \frac{Q_L}{A} C_L^{\text{in}} \eta \quad (2)$$

4 where  $Q_L$  (cm<sup>3</sup>/s) is the liquid flow rate.

5 The CO<sub>2</sub> stripping flux was measured at different liquid flow rates, and the stripping  
 6 efficiency  $\eta$  was calculated from the Eq. (2).

7 Similar to the absorption process, mass transfer resistance in stripping can also be predicted  
 8 by the resistance-in-series model, which considers the resistances from the membrane and liquid  
 9 and gas boundary layers. However, CO<sub>2</sub> transfer direction is reversed from the liquid phase to the  
 10 gas phase under the driving force of CO<sub>2</sub> concentration or partial pressure difference across the  
 11 membrane.

12 To define the overall mass transfer coefficient (MTC), we use the known approach, also used  
 13 for gas absorption simulation in membrane contactors (Sirkar, 1992; Cussler, 1994). In virtue of  
 14 the mass balance of CO<sub>2</sub> in the liquid/gas stripper (the system is assumed to be under steady state  
 15 conditions), the flux in Eq. (2) must be equal to the average flux of CO<sub>2</sub> across the membrane  
 16 ("average" means flux averaging over the length of the channel). This flux can be represented by  
 17 two equivalent ways: through overall MTC based on liquid phase ( $k_{\text{ov}}$ ) or through that ( $k_{\text{ov}}^{(g)}$ ) based  
 18 on gas phase concentrations:

$$J = k_{\text{ov}} \cdot \overline{\Delta C} \quad (3a)$$

$$J = k_{\text{ov}}^{(g)} \cdot \overline{\Delta p} \quad (3b)$$

19 Here  $\Delta C = C_{L(\text{feed})} - C_{L(\text{perm})}$  is the concentration difference of the gas in bulk feed solution and the  
 20 equilibrium concentration of gas in a hypothetical liquid permeate;  $\Delta p = p_{\text{feed}} - p_{\text{perm}}$  is the CO<sub>2</sub>  
 21 partial pressure drop between feed and permeate; bars above quantities denote averaging over the  
 22 length of the channel. Eq. (3) assumes that mass transfer coefficients do not depend on the  
 23 concentration (pressure).

24 The equilibrium concentration of a penetrant gas dissolved in a liquid feed and hypothetical  
 25 liquid permeate can be related to the pressure of the gas by the relation  $C_L = S p$ . We assume that

1 the gas solubility coefficient  $S$  is a constant in the pressure range up to 10 bar. Then two MTCs  
 2 are interconnected as

$$k_{ov}^{(g)} = Sk_{ov} \quad (4)$$

3 As shown in (Cussler, 1994),  $\overline{\Delta C}$  is the logarithmic mean concentration differences of CO<sub>2</sub>  
 4 in the liquid at the inlet and outlet from the membrane contactor. Given that the gas concentration  
 5 in the permeate does not vary with module length, we obtain:

$$\overline{\Delta C} = \frac{\Delta C^{in} - \Delta C^{out}}{\ln(\Delta C^{in}/\Delta C^{out})} = -\frac{C_L^{in}\eta}{\ln(1-\eta/(1-\gamma))} \quad (5)$$

6 where  $\gamma = C_{L(perm)}/C_L^{in} = p_{perm}/p_{feed}$ . As partial permeate pressure is significantly lower than that of  
 7 CO<sub>2</sub> pressure over the liquid entering the membrane contactor, the  $\gamma$  value can be neglected. Then  
 8 Eqs. (2) and (3a) taking into account Eq. (5) gives the following expression for the overall MTC:

$$k_{ov} = -\frac{Q_L}{A} \cdot \ln(1-\eta) \quad (6)$$

9 According to resistance-in-series approach, the overall resistance  $R = 1/k_{ov}$  to gas transfer  
 10 through the membrane can be expressed as the sum of the resistances associated with each phase:  
 11 feed, membrane, and permeate. Using the assumption that the stagnant boundary layer occurs only  
 12 on the feed side of the membrane, i.e. neglecting the gas-phase resistance, we have

$$\frac{1}{k_{ov}} = \frac{1}{k_L} + \frac{1}{k_m} \quad (7)$$

13 It is necessary to emphasize the difference of gas mass transfer from the liquid phase to gas  
 14 phase across porous and nonporous membranes. In the case of a porous membrane, two transfer  
 15 modes are possible: (1) non-wetted where the membrane pores are gas-filled, and (2) wetted mode  
 16 where the membrane pores are liquid-filled. In the case of a non-porous (dense) membrane  
 17 considered in this study, the gas transport through the membrane can be described with the  
 18 solution-diffusion mechanism.

19 The liquid feed mass transfer coefficient  $k_L$  can be expressed via the gas diffusivity  $D$   
 20 across the boundary layer with thickness  $\delta$ , i.e.  $k_L = D/\delta$ ; the membrane mass transfer  
 21 coefficient (the membrane's permeance)  $k_m$  could be written as  $k_m = D_m K/l_m$  where  $D_m$  is the  
 22 diffusion coefficient of the gas through the membrane with thickness  $l$ ,  $K$  is the partition coefficient  
 23 of CO<sub>2</sub> from the feed solution into the membrane (Cussler, 1994). This partition coefficient can be  
 24 written as the ratio of the solubility coefficients of CO<sub>2</sub> in the membrane and feed liquid solution

$$K = S_m/S \quad (8)$$

1 where  $S_m = C_{m,i}/p$ ,  $S = C_{L,i}/p$ ;  $C_{m,i}$  is the concentration of CO<sub>2</sub> in the membrane at the feed  
 2 liquid–membrane interface,  $C_{L,i}$  is the concentration of CO<sub>2</sub> in the feed liquid-phase at this  
 3 interface.

4 In view of the above, the overall resistance will be as follows:

$$R \equiv \frac{1}{k_{ov}} = \frac{\delta}{D} + \frac{l_m S}{P_m} \quad (9)$$

5 Dividing this equation by gas solubility coefficient  $S$ , we get the overall resistance based on gas  
 6 phase:

$$R^{(g)} \equiv \frac{1}{k_{ov}^{(g)}} = \frac{\delta}{P} + \frac{l_m}{P_m} \quad (10)$$

7 where  $P = DS$  and  $P_m = D_m S_m$  are the permeability coefficients of CO<sub>2</sub> in the feed boundary layer  
 8 and the membrane, respectively. If the permeability coefficients are expressed in barrers (1 barrer  
 9 = 10<sup>-10</sup> cm<sup>3</sup>(STP)·cm/(cm<sup>2</sup>·s·cmHg)) and the thickness is in microns, then the dimension of the  
 10 overall resistance  $R^{(g)}$  is GPU<sup>-1</sup> (1 GPU = 10<sup>-6</sup> cm<sup>3</sup>(STP)/(cm<sup>2</sup>·s·cmHg)).

11

## 12 **4. Results and discussion**

### 13 *4.1. Interaction of RTILs with PTMSP*

14 **Table 2** presents the sorption and swelling data of PTMSP in chosen ionic liquids. From data  
 15 obtained one can conclude that: (1) there is no clear dependence between viscosity and sorption  
 16 values; (2) a linear correlation between RTIL surface tension and sorption can be defined – the  
 17 lower surface tension, the higher the liquid sorption value (except two first imidazolium-based  
 18 RTILs). The same reverse dependence was observed earlier for both binary water-ethanol solvents  
 19 and conventional physical CO<sub>2</sub> capture solvents (propylene carbonate, dimethyl ethers of  
 20 poly(ethylene glycole)) (Volkov et al., 2013). PTMSP demonstrated a higher solvent uptake and a  
 21 swelling degree in bulky [P66614][Phos] (MW 773.3) and [P66614][Br] (MW 563.8) liquids  
 22 which are characterized by low surface tension. At the same time, highly polar RTILs with high  
 23 surface tension ([Emim][DCA] and [Emim][BF<sub>4</sub>]) demonstrate a minimum sorption in the  
 24 PTMSP. Thus, these two liquids which exhibit low thermodynamic affinity to the polymer, are  
 25 suitable candidates for application in gas-liquid membrane contactor systems.

26

27

1 **Table 2**

2 Sorption and swelling degree of PTMSP in studied RTILs. The surface tensions and viscosities of  
 3 liquids are also presented (data taken from [Ionic Liquids Database - ILThermo \(v2.0\)](#), Accessed  
 4 [July 07, 2016](#);  $T=25^{\circ}\text{C}$  and  $p=101.325\text{ kPa}$ ).

RTIL	$\eta$ , mPa·s	$\sigma$ , mN/m	Sorption, g/g	Swelling degree, %
[Emim][DCA]	14.5	60.3	0.02	0*
[Emim][BF <sub>4</sub> ]	36.9	54.0	0.02	0*
[Bmim][BF <sub>4</sub> ]	99	44.4	0.79	21
[Hmim][TCB]	49.8	41.1	1.04	44
[Emim][DEP]	457	35.9	1.35	54
[Bmim][Tf <sub>2</sub> N]	50.7	33.0	1.74	57
[P66614][DCA]	439	32.3	1.80	108
[P66614][Br]	2988	29.3	2.11	123
[P66614][Phos]	1402	28.2	2.19	139

5 \*The values obtained are within the measurement accuracy

6

7 The interactions of RTILs with the PTMSP were also evaluated by FTIR spectroscopy. For  
 8 this purpose, the PTMSP films after sorption/swelling experiments with RTILs were used. Two  
 9 liquids with a high surface tension ([Emim][DCA], [Emim][BF<sub>4</sub>]) and the two liquids with low  
 10 surface tension ([P66614][Br], [P66614][Phos]) have been chosen.

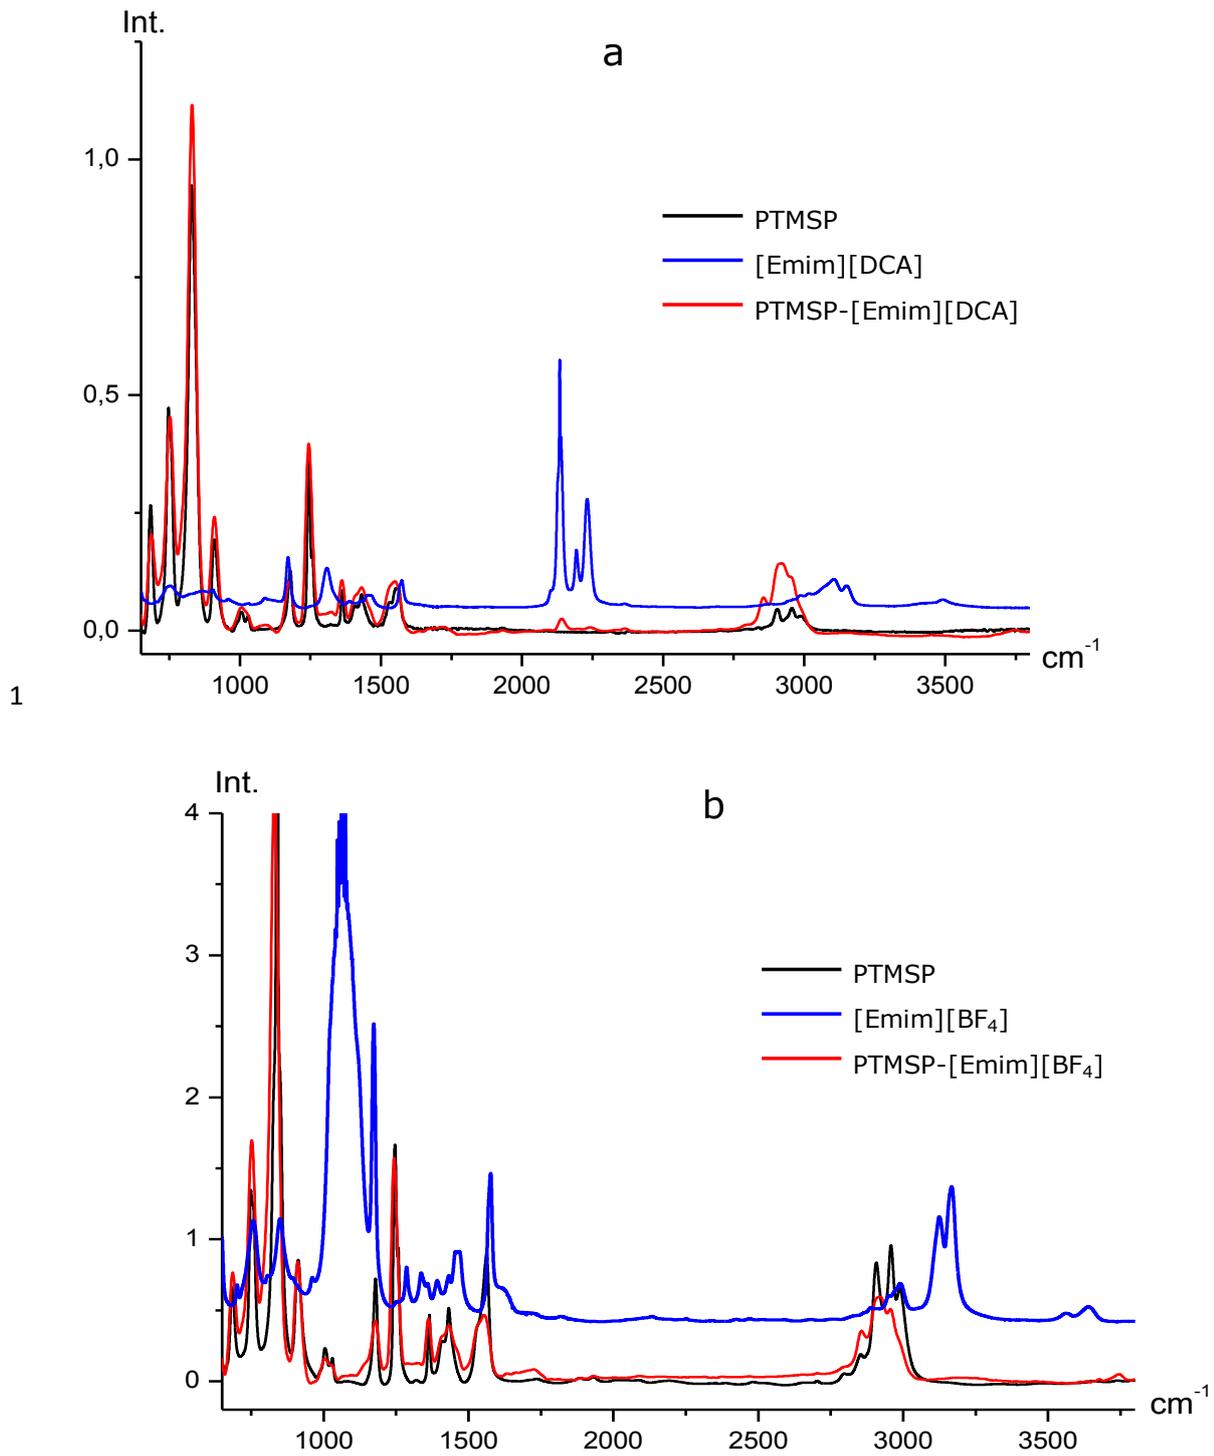

11 The reflection spectra for swollen PTMSP, and also spectra for pure PTMSP and RTILs are  
 12 shown in [Fig. 3](#) and [4](#). The weak bands in the range of 2100-2200 cm<sup>-1</sup> from valence vibrations of  
 13 the [DCA]<sup>-</sup> anion nitrile groups in the PTMSP-[Emim][DCA] spectrum ([Fig. 3a](#)) indicate RTIL  
 14 presence in the polymer film; however, its concentration in the polymer is very small. The detailed  
 15 consideration of the spectrum in [Fig. 3a](#) shows some changes of absorption bands for both the  
 16 polymer and RTIL. The 828, 910 and 683 cm<sup>-1</sup> bands associated with the valence vibrations of Si-  
 17 C bonds in the polymer and remain without any noticeable changes in PTMSP-solvent sample.  
 18 The 747 cm<sup>-1</sup> band is responsible for complex oscillative motion in PTMSP. This band not only  
 19 shifts towards short waves but also loses splitting which is typical for the polymer having mixed  
 20 microstructure (*cis-trans*). The described spectrum features for such a rigid polymer as PTMSP  
 21 can be related to the symmetry breaking in the polymeric unit, accompanied by a change in the

1 backbone conformation. Detectable changes influenced by [Emim][DCA] occur in the polymer  
2 spectrum in the region of the C=C bond valence vibrations (1540-1580  $\text{cm}^{-1}$ ). Three bands,  
3 characteristic for the double bond in the PTMSP unit, and one band derived from skeletal  
4 vibrations in the [Emim][DCA] cation imidazole ring, merge into one wide band in the soaked  
5 polymer spectrum. Significant changes in the imidazole ring structure are also observed, namely,  
6 bands intrinsic to the =CH bonds vibrations in the ring (3100-3200  $\text{cm}^{-1}$ ) have totally disappeared.  
7 This suggests that the aromaticity of RTIL cation was strongly affected by polymer-RTIL  
8 interaction. Fig. 3b shows the PTMSP-[Emim][BF<sub>4</sub>] spectrum compared to that of PTMSP and  
9 [Emim][BF<sub>4</sub>]. The RTIL content in the polymer also marginally. The polymer spectrum undergoes  
10 almost the same changes as those in the case of [Emim][DCA]; significant changes are observed  
11 in the region of double bonds and bands, sensitive to chain conformation.

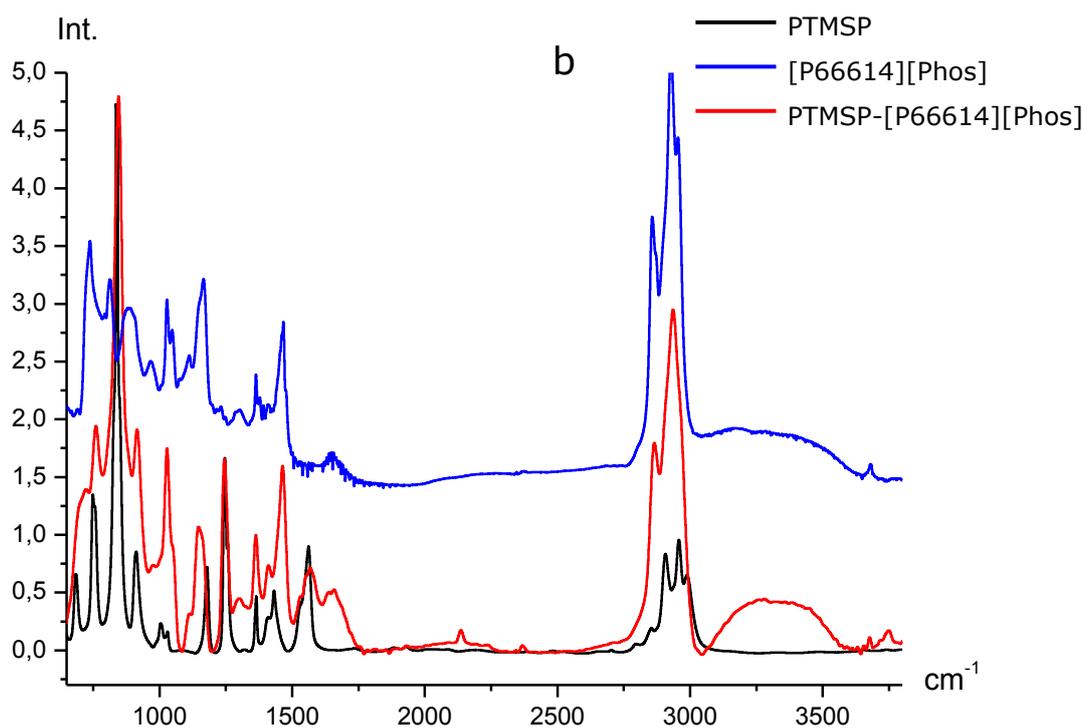

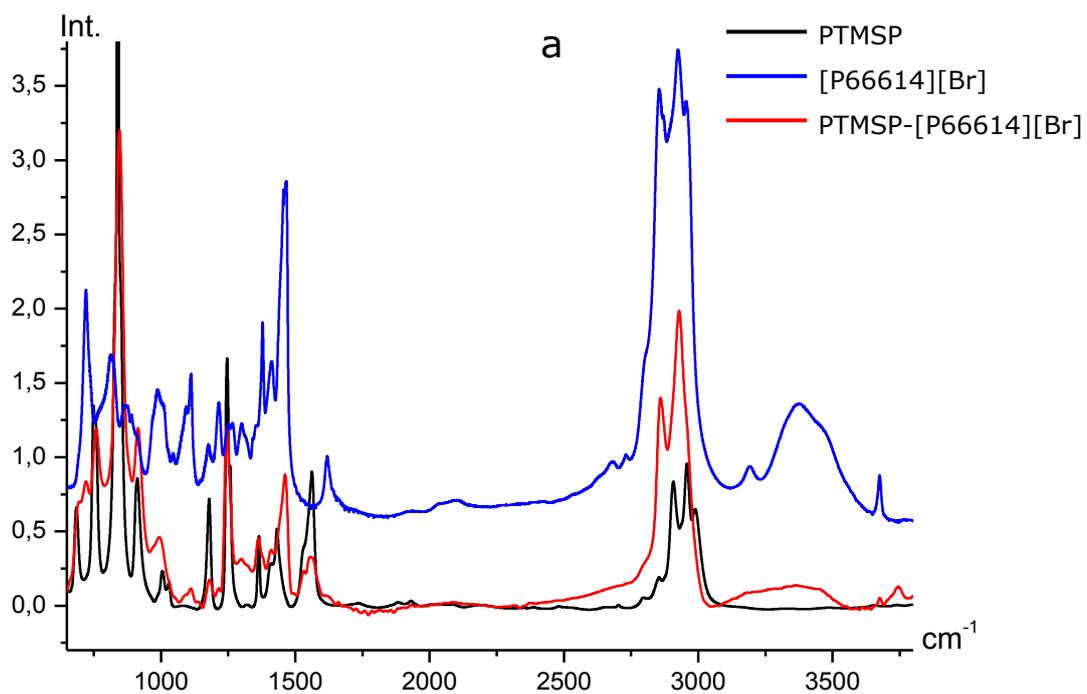

12 Fig. 4 shown the spectra of PTMSP with phosphonium-based RTILs: [P66614][Br] and  
13 [P66614][Phos]. The spectra show a higher liquid content in the polymer compared with the  
14 aforementioned liquids. Amount of [P66614][Br] in PTMSP (Fig. 4a) is lower than that of  
15 [P66614][Phos] (Fig. 4b), which is in agreement with sorption data. In the case of [P66614][Br],  
16 [Br]<sup>-</sup> anion does not have intrinsic bands in FTIR spectrum. The particular intensity of  
17 phosphonium-based compounds bands is observed in the spectra for PTMSP film soaked in  
18 [P66614][Phos] (Fig. 4b). In this spectrum, considerably intensive bands of the RTIL strongly  
19 shifted towards the long-wave region: the P=O band of the RTIL anion 1166  $\text{cm}^{-1}$  shifts to 1148  
20  $\text{cm}^{-1}$  and the P-CH<sub>2</sub> band of the RTIL 738  $\text{cm}^{-1}$  shifts to 718  $\text{cm}^{-1}$ .

21 Analysis based on quantum chemical calculations shows that =C-Si bond in the monomeric  
22 unit of PTMSP is strongly polar: a high positive charge (1.190 e) occurs on the silicon atom, and  
23 a significant negative charge (-0.363 e) occurs on the carbon atom at double bond [Legkov et al.,  
24 2012]. Given this, it can be assumed that the interaction of the RTIL with the polymer occurs due  
25 to the coordination of the cation and the anion of the RTIL towards oppositely charged PTMSP  
26 atoms. This interaction is accompanied by a change in the conformation of the chain and  
27 redistribution of the electron density in the -C=C-SiMe<sub>3</sub> unit.

28

**Fig. 3.** FTIR spectra of swollen film of PTMSP in ionic liquids: [Emim][DCA] (a) and [Emim][BF<sub>4</sub>] (b). Spectra of pure PTMSP and individual liquids are also shown.

**Fig. 4.** FTIR spectra of swollen film of PTMSP in ionic liquids: [P66614][Br] (a) and [P66614][Phos] (b). Spectra of pure PTMSP and individual liquids are also shown.

FTIR data testify that phosphonium-based RTILs interact with PTMSP significantly higher than imidazolium-based ones; this manifests itself in a higher concentration of first type RTILs in the polymer compared with second type ones.

1 As was shown above (Table 2), sorption of phosphonium-based RTILs in PTMSP is one  
2 order of magnitude higher than that for imidazolium-based RTILs. Thus, the conclusions obtained  
3 from FTIR spectroscopy data are consistent with the results of sorption measurements.

4 Following on from the results of sorption and FTIR data, it is reasonable to expect that  
5 PTMSP might possess barrier properties towards [Emim][DCA] and [Emim][BF<sub>4</sub>] and be  
6 permeable for [P66614][Br] and [P66614][Phos]. The membrane leakage testing with chosen  
7 RTILs confirmed these expectations. Taking into account the high viscosity of ionic liquids and  
8 possible change of their macroscopic properties as a result of CO<sub>2</sub> loading, the membrane cell was  
9 pressurized by carbon dioxide and continuously kept under the operating pressure during at least  
10 400 hours. No hydrodynamic flow of [Emim][BF<sub>4</sub>] or [Emim][DCA] through PTMSP membranes  
11 was visually observed during these leakage tests. At the same time, the experiment showed the  
12 absence of PTMSP barrier properties toward phosphonium-based RTILs: the visual study showed  
13 the presence of RTIL leakage through the PTMSP membranes after approx. 220-260 h of testing.  
14 Earlier it was shown for PTMSP/water/ethanol system (Volkov et al., 2013; Yushkin et al., 2015)  
15 that surface tension has a significant effect on the appearance of hydrodynamic permeability of the  
16 polymer and, hence, the applicability of this membrane material in high-pressure gas-liquid  
17 contactors. It was also recently estimated (Filippov et al., 2015) that the critical entry pressure, i.e.  
18 the trans-membrane pressure at which liquid penetrates into the pores of the membrane, of water-  
19 ethanol mixtures in PTMSP might reach 100 bar or even higher for the solutions with a surface  
20 tension of 50 mN/m or higher. This estimation is in a good agreement with our finding that PTMSP  
21 is impermeable at transmembrane pressures up to 40 bar for [Emim][DCA] and [Emim][BF<sub>4</sub>]  
22 having  $\sigma > 50$  mN/m. It should be noted that porous membranes commonly used in gas-liquid  
23 contactors become wetted and permeable at much lower pressure. For example, in the case of  
24 PTFE membranes, the critical entry pressure is lower than 3 bar for water-ethanol solvents with  
25  $\sigma > 50$  mN/m (Dindore et al., 2004). Such advantage of the dense membranes over hydrophobic  
26 porous membranes provide greater flexibility in selection of CO<sub>2</sub> solvents especially for high-  
27 pressure applications such as pre-combustion or natural gas sweetening.

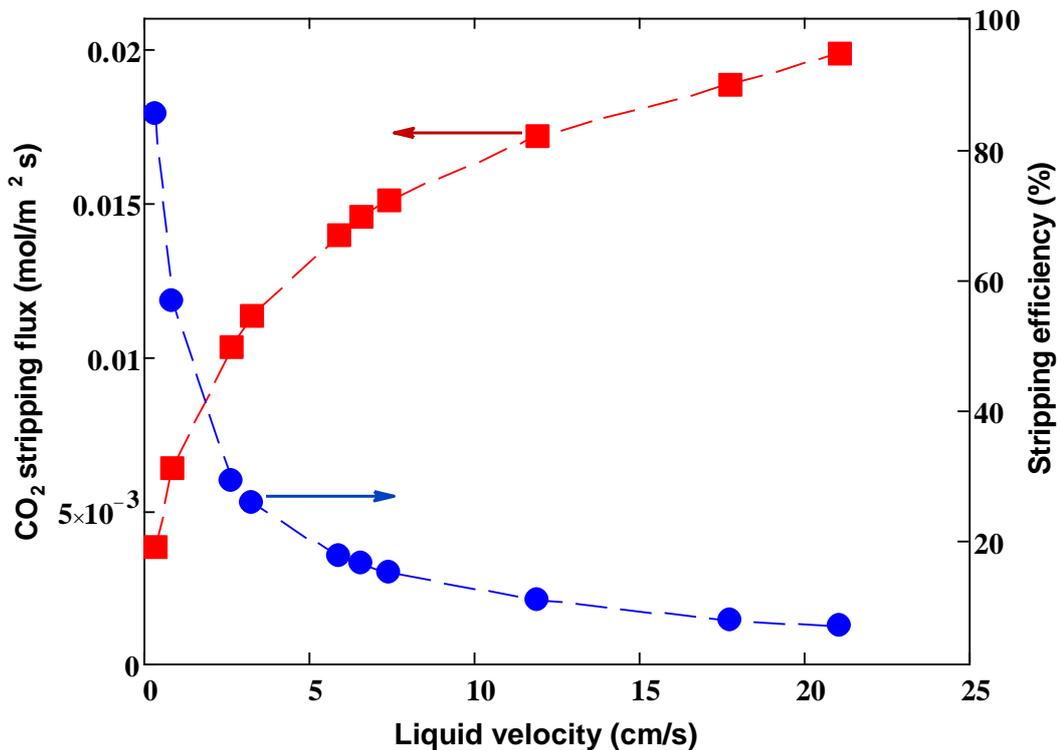

#### 28 29 4.2. CO<sub>2</sub> stripping from the RTIL in membrane contactor

30 The proof of principle of high-pressure gas-liquid membrane contactor for CO<sub>2</sub> stripping  
31 from RTIL solvent was verified by using [Emim][BF<sub>4</sub>] and the flat-sheet PTMSP membrane. From  
32 the pair [Emim][BF<sub>4</sub>] and [Emim][DCA] the first one was chosen based on literature data for CO<sub>2</sub>  
33 solubilities: CO<sub>2</sub> sorption capacity of [Emim][BF<sub>4</sub>] is higher than that of [Emim][DCA], which is

1 depicted by a lower value of Henry's law constant, 3.0465 MPa (Soriano et al., 2008) and 9.5955  
2 MPa (Camper et al., 2005) at 40°C, respectively.

3 The dense PTMSP membrane separates the two phases within the gas-liquid contactor: feed  
4 solution of CO<sub>2</sub> in the ionic liquid at 10 bar as in the absorber and permeate gas phase under the  
5 atmospheric pressure. Sweep gas or vacuum was not used, so, permeate constituted a stagnant gas  
6 layer. CO<sub>2</sub>-saturated RTIL [Emim][BF<sub>4</sub>] is convected parallel to the membrane surface through  
7 the rectangular channel with the cross-sectional area  $A_{ch} = Lh$  (channel height  $h = 0.01$  cm and  
8 channel length  $L = 4$  cm), carbon dioxide diffuses through the membrane and then desorbes to the  
9 permeate collector of the contactor. Inlet concentration of the gas in [Emim][BF<sub>4</sub>] on the channel  
10 is equal to the equilibrium one at CO<sub>2</sub> pressure of 10 bar and a temperature of 303 K within the  
11 absorber. At these  $p$  and  $T$  conditions this concentration is 0.43 mol/kg RTIL or 0.54 mol/L (molar  
12 fraction is 7.6%) (Soriano et al., 2008).

13 Fig. 5 shows the results of CO<sub>2</sub> stripping from [Emim][BF<sub>4</sub>] as a function of liquid flow-rate.  
14 CO<sub>2</sub> stripping flux was measured directly in the experiment at different flow-rates; the stripping  
15 efficiency was further calculated from CO<sub>2</sub> stripping flux data with Eq. (2).

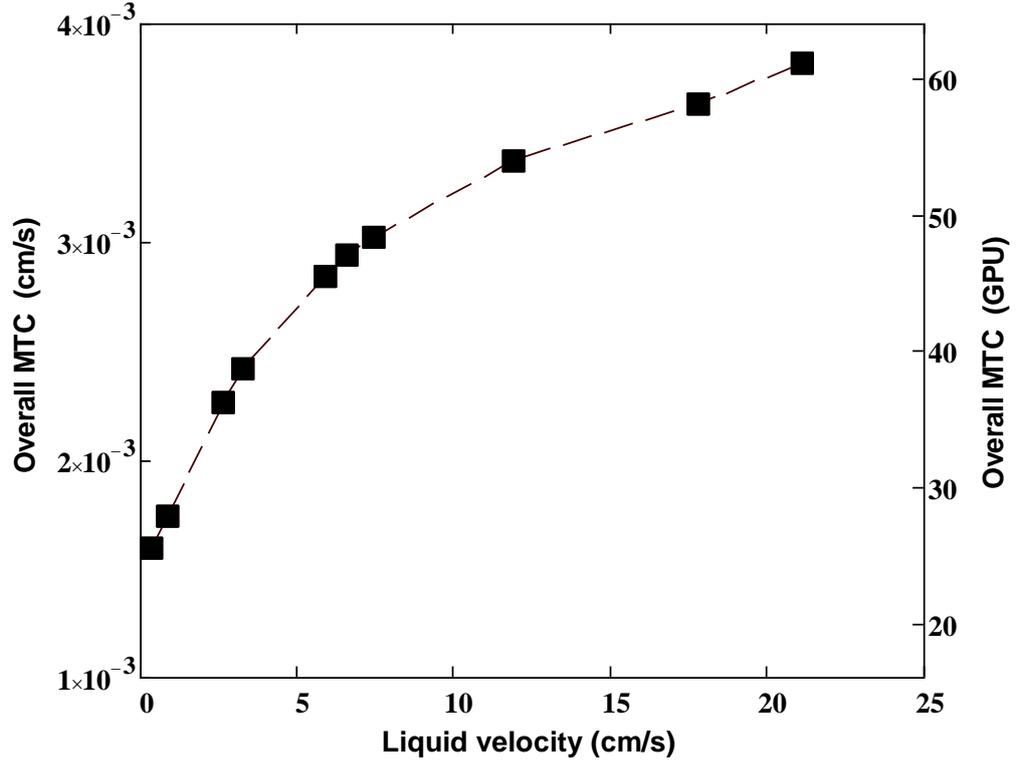

16  
17 Fig. 5. The stripping efficiency and CO<sub>2</sub> stripping flux vs. the liquid velocity. The liquid velocity  $u = Q_L/A_{ch}$   
18 where  $A_{ch}$  is the cross-sectional area of the liquid channel, temperature and trans-membrane pressure in the contactor  
19 are 30°C and 10 bar.

20

1 As can be seen from Fig. 5, CO<sub>2</sub> stripping flux increased with the liquid velocity, while the  
2 efficiency decreases (trade-off between  $J$  and  $\eta$ ). It is evident that a slower liquid velocity leads  
3 to an increase in residence time of solvent in slit channel of membrane contactor and, consequently,  
4 to higher values of  $\eta$ . As flux is proportional to the product of  $Q_L$  and  $\eta$ , the flux increases with  
5 the liquid velocity with a gradually decreasing slope. A similar behavior was observed,  
6 particularly, in Ref. (Khaisri et al., 2011). The trade-off between the flux and the efficiency  
7 assumes that  $J \times \eta$  function passes through a maximum. A simple estimation shows that the  
8 maximum of the product of  $J$  and  $\eta$  is achieved at the liquid velocity of about 1.2 cm/s. In this  
9 context, this is the preferable liquid solution velocity for the system investigated. At this velocity,  
10  $\eta \approx 48\%$  and  $J = 0.0074 \text{ mol}/(\text{m}^2 \text{ s})$  (1.2 kg/m<sup>2</sup> h). **It should be noted that this value is two orders**  
11 **of magnitude higher than that obtained for membrane contactor based on porous polypropylene**  
12 **hollow fibers with analogous imidazolium-based IL – [Bmim][BF<sub>4</sub>] (maximal value  $\sim 3.5 \times 10^{-5}$**   
13 **mol/(m<sup>2</sup> s), see Lu et al., 2014).**

14 Calculation based on Eq. (6) showed that overall MTC increases with an increase in liquid  
15 velocity from  $1.6 \cdot 10^{-3} \text{ cm/s}$  at  $u = 0.33 \text{ cm/s}$  to  $3.8 \cdot 10^{-3} \text{ cm/s}$  at  $u = 21 \text{ cm/s}$  (Fig. 6). Solubility  
16 coefficient of CO<sub>2</sub> in [Emim][BF<sub>4</sub>] is equal to  $S = 0.054 \text{ mmol}/(\text{cm}^3 \cdot \text{bar})$  or  $0.016 \text{ cm}^3$   
17 (STP)/(cm<sup>3</sup>·cm Hg) at 303 K, as it follows from Ref. (Soriano et al., 2008). Consequently, overall  
18 MCT based on gas phase  $k_{ov}^{(g)} = S k_{ov}$  ranges within 25-61 GPU. **Comparison of calculated overall**  
19 **MTC with available literature data for membrane contactors with analogous imidazolium-based**  
20 **ILs shows that MTC is also higher in our case:  $(1.1-3.2) \times 10^{-4} \text{ cm/s}$  for [Emim][Ac] and  $0.7 \times 10^{-4}$**   
21 **cm/s for [Emim][EtSO<sub>4</sub>] within membrane contactor with polypropylene hollow fibers (Gómez-**  
22 **Coma et al., 2014);  $(0.365-1.01) \times 10^{-4} \text{ cm/s}$  for [Bmim][TCM] within membrane contactor with**  
23 **tubular glass membranes (Dai et al. (2016));  $(2.4-3.7) \times 10^{-4} \text{ cm/s}$  for [Emim][Ac] within**  
24 **membrane contactor with polysulfone hollow fibers (Gómez-Coma et al., 2016);  $(0.9-1.67) \times 10^{-3}$**   
25 **cm/s for [Bmim][DCA] within membrane contactor with polypropylene hollow fibers (Mulukutla**  
26 **et al., 2014). Almost all the compared works used contactors with porous membranes which can**  
27 **suffer from the wetting effect resulted in lower overall MTCs. An exception is the latter publication**  
28 **where authors used PP hollow fibers with thin plasma polymerized hydrophobic porous**  
29 **fluorosiloxane coating on the outer surface of the fiber: overall MTC is comparable with ours.**

1  
2 **Fig. 6.** The overall MTC for CO<sub>2</sub> stripping from [Emim][BF<sub>4</sub>] in the PTMSP-based flat-sheet membrane  
3 contactor as a function of the liquid velocity; temperature and trans-membrane pressure in the contactor are 30°C and  
4 10 bar.

5  
6 As defined above (Eq. (10)), the overall resistance to gas transfer is the sum of the  
7 resistances associated with the liquid phase and the membrane.

8 The question arises, which of the contributions into the overall resistance dominates – the  
9 membrane resistance  $R_m = l_m/P_m$  or the liquid layer resistance  $R_L = \delta/P$ . The permeability of the  
10 PTMSP membrane, containing ionic liquid, can be approximated by the series model:

$$\frac{1}{P_m} = \frac{\phi}{P} + \frac{1-\phi}{P_p} \quad (11)$$

11 where  $\phi$  is the volume fraction of the RTIL in the membrane,  $P_p$  is the permeability of the pure  
12 polymeric membrane. It should be noted that the series model gives a lower bound for permeability  
13 compared to that in other models for binary polymer systems (Robeson, 2010). So, in the absence  
14 of experimental data for permeability of the polymer/ionic liquid membrane, the use of  
15 approximation (11) will give an *upper estimate* for the membrane resistance. Furthermore, the  
16 membrane thickness change due to its swelling should be taken into account. The thickness of the  
17 swollen membrane  $l_m$  is related to the thickness of dry membrane  $l$  as  $l_m = l(1-\phi)^{n-1}$  where

1  $n = 2/3$  in the case of isotropic swelling and  $n = 0$  for fully anisotropic swelling (Bitter, 1984).  
2 Under the conditions of stripping experiments, the membrane is assumed to swell only in the  
3 direction that is perpendicular to the membrane surface due to its confinement on the support,  
4 therefore the relation can be adopted as follows:

$$l_m = l/(1 - \phi) \quad (12)$$

5 On substituting Eqs. (11) and (12) into Eq. (10), we obtain the following:

$$R^{(g)} = R_L + R_m = \frac{\delta}{P} + \frac{l}{P_p} \beta \quad (13)$$

6 where  $\beta = 1 + \frac{\phi}{1 - \phi} \frac{P_p}{P}$  is the factor that describes the increasing of membrane resistance due to  
7 the liquid sorption in the polymer. Thus, Eq. (13) states that the overall resistance to gas transfer  
8 is the sum of the liquid film resistance and the pure polymer membrane resistance multiplied by  
9 sorption (wetted) factor.

10 The volume fraction of the used RTIL in PTMSP can be estimated from the following  
11 relation (assuming volume additivity upon mixing):

$$\phi = \frac{w}{w + (1 - w) \rho / \rho_p} \quad (14)$$

12 where  $w$  is the weight fraction of RTIL in PTMSP,  $\rho = 1.28 \text{ g/cm}^3$  and  $\rho_p = 0.78 \text{ g/cm}^3$  are the  
13 densities of the [Emim][BF<sub>4</sub>] and PTMSP, respectively. Our sorption measurements resulted in  
14  $w = 2 \text{ wt } \%$ , so that the volume fraction  $\phi = 1.3 \text{ vol. } \%$ . This value was used for the evaluation of  
15 membrane resistance.

16 The permeability coefficient of CO<sub>2</sub> in used RTIL is also needed for the membrane  
17 resistance calculation and can be taken from works considering gas permeability of supported  
18 liquid membranes (Jiang et al., 2007; Scovazzo et al., 2009). Despite the use of very similar  
19 microporous supports (a hydrophilic polyethersulfone support with 80% porosity), average  
20 permeability values obtained in these papers differ for almost 2-fold. Such difference in  
21 permeability seems to be related not only to the difference between the measurement techniques  
22 but also to the IL purity (moisture content and other impurities). It should be noted that that authors  
23 of (Scovazzo et al., 2009) state that their measurements are “the gas permeabilities of free liquid  
24 RTIL and not the permeabilities of RTIL-membranes”. The data for two published values of  
25 permeabilities for [Emim][BF<sub>4</sub>] are summarized in the Table 3. Permeability coefficient of pure  
26 PTMSP membrane ( $P_p$ ) is much greater than for the ionic liquid ( $P$ ). However, sorption of

[Emim][BF<sub>4</sub>] in the polymer reduces the permeability coefficient of the membrane by 26-42% ( $P_m$ ), depending on the reference value of the  $P$ .

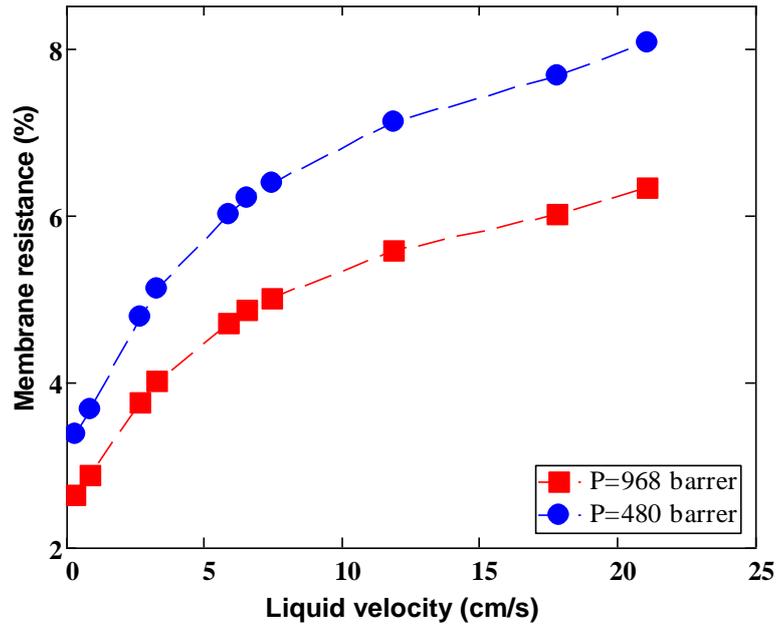

**Table 3**

$P_p$ ,  $P$  and  $P_m$  are the CO<sub>2</sub> permeability coefficients (in barrer) of pure PTMSP, [Emim][BF<sub>4</sub>] and the membrane (membrane thickness is 21  $\mu\text{m}$ ), respectively;  $\beta$  is sorption factor at  $\phi = 1.3$  vol. %,  $R_m$  is the membrane resistance (in 1/GPU).

$P_p$	$P$	$P_m$	$\beta$	$R_m$
27600	480 (Jiang et al., 2007)	15912	1.76	$1.34 \cdot 10^{-3}$
	968 (Scovazzo et al., 2009)	20329	1.38	$1.05 \cdot 10^{-3}$

According to our estimates (see Fig. 6), the reciprocal overall MTC (i.e. the overall resistance) is varied from 0.04 to 0.016 GPU<sup>-1</sup> with the liquid velocity. The membrane resistance (Table 3) is an order of magnitude less than the overall resistance. The fraction of the membrane resistance  $R_m/R^{(g)}$  for the two values of CO<sub>2</sub> permeability in the ionic liquid is shown in Fig. 7.

In the case of  $P = 468$  barrer, this contribution ranges from 3.4 to 8.1% as liquid velocity increase from 0.33 to 21 cm/s. If the CO<sub>2</sub> permeability of the ionic liquid is equal to 986 barrer, the largest contribution of the membrane to the overall resistance is 6.3%. In any case, it is evident that the liquid phase mass transfer resistance is the dominating contribution to the overall resistance. As can be seen from Fig. 7, the higher the liquid flow rate, the greater the contribution of the membrane resistance into overall resistance. As the permeability coefficients are independent of the liquid velocity, the second term in Eq. (13) is also independent of the liquid velocity. Then, the sole reason for the increase of the membrane resistance contribution is the liquid phase resistance decrease. This decrease can occur by reducing the thickness of liquid boundary layer.

1  
2 **Fig. 7.** The membrane contribution to overall mass-transfer resistance at two literature values of the CO<sub>2</sub>  
3 permeability of [Emim][BF<sub>4</sub>]; volume fraction of [Emim][BF<sub>4</sub>] is 1.3 %; thickness of the unswollen membrane is 21  
4 μm; temperature is 30°C.

5  
6 The boundary layer thickness can be determined once the overall and membrane resistances  
7 are known. It follows from Eq. (13) that

$$\delta = P(R^{(g)} - R_m) \quad (15)$$

8 at given liquid velocity. Obtained data has been fitted with the power function

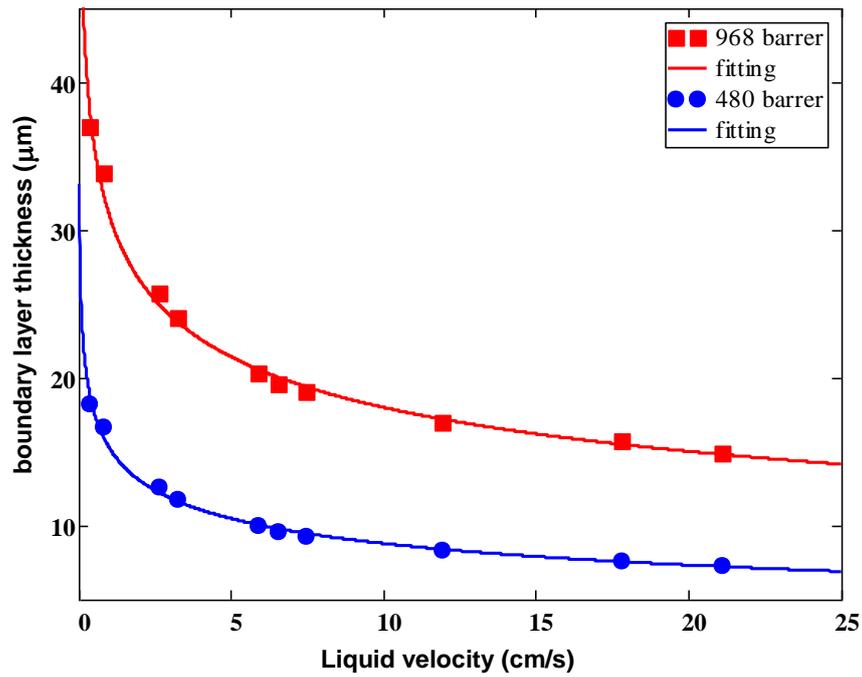

$$\delta^{-1}(u) = au^q + b \quad (16)$$

9 The best fit of this function to the data calculated from Eq. (15) is obtained for the following  
10 parameters:  $a = 0.022$ ,  $b = 0.010$ ,  $q = 0.312$  if CO<sub>2</sub> permeability coefficient in the RTIL  $P = 968$   
11 barrer and  $a = 0.046$ ,  $b = 0.019$ ,  $q = 0.310$  if  $P = 480$  barrer (Fig. 8). It should be noted that  
12  $\delta^{-1} \propto u^{0.31}$  in both cases. As expected, the boundary layer thickness decreases with the liquid  
13 velocity. The liquid film thickness velocity is higher in the case of  $P = 968$  barrer, than in the case  
14 of  $P = 480$  barrer.

15 As known, liquid phase mass transfer coefficient  $k_L$  in dimensionless form is the Sherwood  
16 number. As  $k_L = D/\delta$ , the Sherwood number is expressed as

$$\text{Sh} \equiv \frac{k_L d_h}{D} = \frac{d_h}{\delta} \quad (17)$$

1 where  $d_h$  is the hydraulic diameter of the channel,  $D$  is the gas diffusivity across the liquid  
 2 boundary layer. In the case of the slit channel  $d_h \cong 2h$  with  $h$  being the channel height. The value  
 3 of the liquid film thickness can be predicted from Sherwood relations, which are represented as  
 4  $Sh = c Re^q Sc^r$  (Gabelman and Hwang, 1999). Here  $Re$  is the Reynolds number ( $Re = \rho u d_h / \mu$ ),  
 5  $Sc$  is the Schmidt number ( $Sc = \mu / \rho D$ ),  $\mu$  is the liquid viscosity, and  $c$ ,  $q$ , and  $r$  are adjustable  
 6 parameters. These parameters depend on the flow conditions (laminar, turbulent), the membrane  
 7 module design, etc.

8  
 9 **Fig. 8.** The thickness of liquid boundary layer as a function of the RTIL velocity at two literature values of  
 10  $CO_2$  permeability across [Emim][BF<sub>4</sub>]. Points are the calculated values based on experiment and resistance-in-series  
 11 model (Eq. (15)), solid lines were fitted using the power function of Eq. (16).  
 12

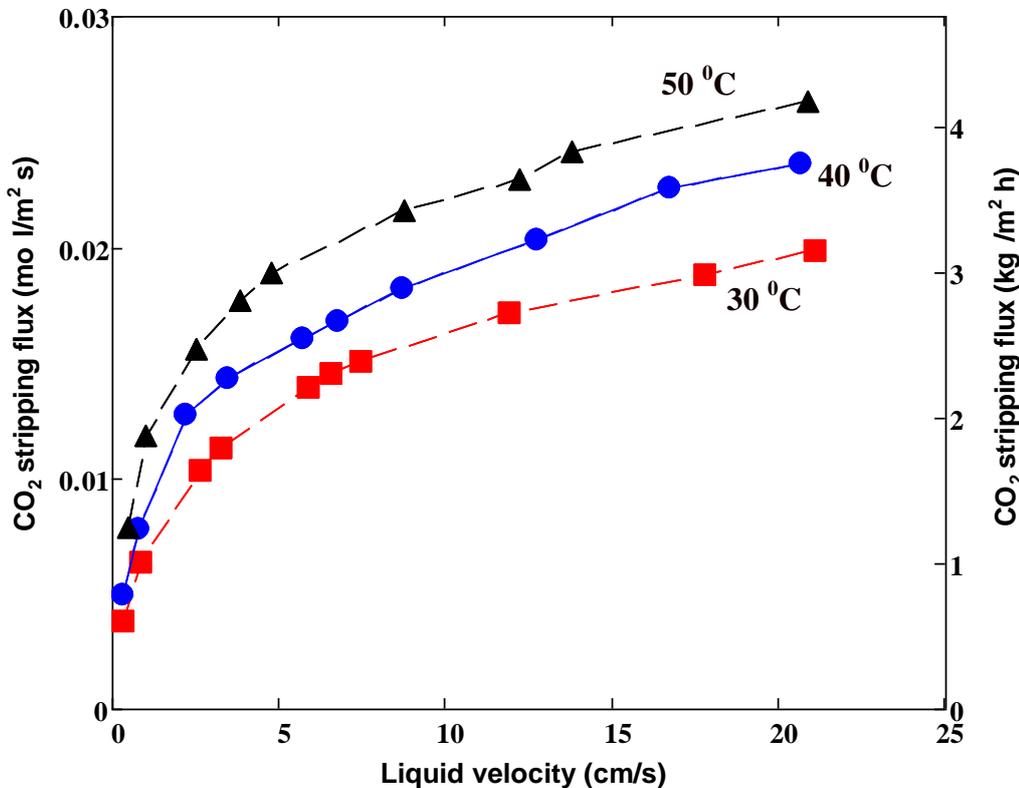

13 For the flow of ionic liquid [Emim][BF<sub>4</sub>] in the slit channel, the range of the Reynolds  
 14 numbers was found to be 0.02-1.4. Sherwood's correlations for so small Reynolds numbers are  
 15 uncommon in the literature. In this respect, it is necessary to notice the articles of Sirkar and  
 16 coworkers (Bhaumik et al., 1998; Mulukutla et al., 2014) in which the following correlation was  
 17 used for hollow fiber membranes:

$$Sh = 0.57 Re^{0.31} Sc^{0.33} \text{ for } 0.01 < Re < 1 \quad (18)$$

18 In this situation, as follows from Eqs. (17) and (18), the reciprocal thickness of the liquid  
 19 film is proportional to the liquid velocity with the exponent coefficient 0.31. It is interesting to

1 note that the same exponent is obtained by us above in the approximation of the boundary layer  
2 thickness. Moreover, our data presented in Fig.8 shows quantitative fit with the Eq. (18) at an  
3 insignificant correction of the first factor in this equation.

4 The experiments were carried out for two cases: (1) absorption and stripping temperatures  
5 are equal; (2) stripping temperature is higher than the absorption one. The CO<sub>2</sub>-saturated RTIL is  
6 pressurized up to 10 bar for both cases. The CO<sub>2</sub> stripping flux was measured after achieving  
7 steady state. The results are presented in Fig. 9 (for convenience, the flux is also given in units of  
8 kg·m<sup>-2</sup>·h<sup>-1</sup>). As expected, the CO<sub>2</sub> stripping flux increases with application of higher temperatures:  
9 temperature rise from 30 to 50°C increases the CO<sub>2</sub> flux by more than 30%. This is the result of  
10 lower CO<sub>2</sub> solubility in [Emim][BF<sub>4</sub>] (Soriano et al., 2008). Thus the increasing of temperature is  
11 a promising operation to enhance the CO<sub>2</sub> stripping process.

12  
13 Fig. 9. The stripping CO<sub>2</sub> flux vs. the liquid velocity at different stripping temperatures in the dense membrane  
14 contactor.

15  
16 As shown earlier (Trusov et al., 2011; Bazhenov et al., 2012; Grekhov et al., 2012; Volkov et al.,  
17 2013), PTMSP possesses barrier properties towards different solvents at higher temperatures and  
18 pressures (up to 100°C and 50 bar). This allows to further intensify CO<sub>2</sub> stripping flux within dense  
19 PTMSP membrane contactor.

1

## 2 **5. Conclusions**

3 In this study, we provide the proof-of-concept of CO<sub>2</sub> stripping from ionic liquids as a solvent  
4 with membrane contactor at elevated trans-membrane pressure. For this purpose, we used dense  
5 flat-sheet membranes made from highly permeable polymer PTMSP. To prove the possibility of  
6 its application, a screening test on the membrane-RTIL compatibility in nine different ionic liquids  
7 was carried out. The results clearly depicted that the interaction of RTILs with PTMSP is  
8 correlated with liquid surface tension: the higher the surface tension of RTIL, the lower the values  
9 of sorption and volumetric swelling degree. The liquid-polymer interactions were studied by FTIR  
10 spectroscopy for RTILs with least ([Emim][DCA], [Emim][BF<sub>4</sub>]) and highest ([P66614][Br],  
11 [P66614][Phos]) sorption values. It turned out that cations and anions of RTILs can coordinate  
12 towards oppositely charged PTMSP atoms thus causing chain conformation change and electron  
13 density redistribution within the polymeric unit. FTIR results correspond well to sorption data.  
14 Finally, the long-term RTIL permeation study confirmed that PTMSP membranes are indeed  
15 impermeable to [Emim][DCA] and [Emim][BF<sub>4</sub>] at a trans-membrane pressure of 40 bar, that  
16 makes it possible to use these RTILs as CO<sub>2</sub> solvents within membrane contactors.

17 CO<sub>2</sub> stripping tests were carried out in the flat sheet membrane contactor at temperature 30°C  
18 and transmembrane pressure 10 bar using [Emim][BF<sub>4</sub>] as a demo solvent. Results indicated that  
19 CO<sub>2</sub> stripping flux  $J$  increases, and, in contrast, the stripping efficiency  $\eta$  decrease with the liquid  
20 flow rate. Under optimal liquid velocity value (when the product of  $J$  and  $\eta$  is maximal),  $J = 1.2$   
21 kg/m<sup>2</sup>·h and  $\eta = 48\%$ . Using the resistance-in-series model, the membrane resistance contribution  
22 to the gas transfer was estimated about 8% under the maximum liquid velocity, which means that  
23 the main mass transfer resistance is located in the liquid boundary layer. Experiments showed that  
24 the increasing of stripping temperature from 30 to 50°C gives the possibility to obtain significant  
25 (30% and higher) growth of the CO<sub>2</sub> stripping flux in the membrane contactor. PTMSP membranes  
26 provide an absence of solvent leakage at elevated temperatures and pressures. This lays the  
27 groundwork for further increasing of CO<sub>2</sub> stripping performance from RTILs using dense  
28 ultrapermeable membranes.
