MATERIAL GUIDE for GREEN 3D PRINTING

This material selection guide can be used to make greener material choices for FDM Printing, alongside functional and aesthetic requirements. Higher scores imply better material properties.

MECHANICAL PROPERTIES

Tensile Modulus Resistance to deforming under tension. Higher tensile modulus

means lower elasticity.

Ultimate Tensile Strength Maximum stress that the

material can withstand before breaking under tension.

Elongation

Ratio between changed length and initial length after breaking under tension.

*Mechanical properties for materials PLAYPHAB and OMNI are estimated to be similar to PLAPHA and UM-TPLA respectively.

PRINT QUALITY

UM-PLA

UM-TPLA

omni

PLAPHA

UM-CPE

BIOPETG

PLAYPHAB

Dimensional accuracy

How well a printed object matches the dimensions of the original file.

Overhangs

The extent to which parts of the 3D print can extend outward beyond the previous layer with no extra support.

Bridging

The extent to which material can be extruded between two points with no support from below.

Fine Features How well the features with

smaller dimensions can be printed with a clean finish.

SUSTAINABILITY

	Energy Efficiency	Energy use/unit**	Source	End of Life
UM-PLA		0.33 kWh/unit	Ø	
UM-TPLA		0.39 kWh/unit		
ALGA		0.386 kWh/unit	Ø	
OMNI		0.316 kWh/unit		
PLAPHA		0.377 kWh/unit	Ø	
PLAYPHAB		0.343 kWh/unit	Ø	
UM-CPE		0.447 kWh/unit		
BIOPETG		0.651 kWh/unit		

Energy Efficiency More energy efficient means less energy use per part printed Source Bio-based/ fossil-based End of Life

Biodegradable/ Non-biodegradable

**One unit refers to the 'Apple shell' part used for universal comparisons - https://www.thingiverse.com/thing:4031080
