ABSTRACT

It is challenging to rational design persistent luminescence and storage phosphors with high storage capacity of electrons and holes after X-ray charging. Such phosphors have potential applications in anti-counterfeiting and X-ray imaging. Here we have combined vacuum referred binding energy diagram (VRBE) construction, photoluminescence spectroscopy, and thermoluminescence to study the trapping processes of charge carriers in NaYGeO_4 . In $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.004\text{Bi}^{3+},0.005\text{Ln}^{3+}$ ($\text{Ln} = \text{Tb}$ or Pr), Bi^{3+} appears to act as a shallow electron trap, while Bi^{3+} and Ln^{3+} act as deep hole trapping and recombination centres. We will show how to experimentally determine the VRBE in the $\text{Bi}^{2+} \ ^2\text{P}_{1/2}$ ground state in NaYGeO_4 and NaLuGeO_4 by thermoluminescence study. The electron trap depth produced by Bi^{3+} codopant in $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ can be adjusted, by increasing x , resulting in conduction band engineering. By combining Bi^{3+} as an electron trap and Bi^{3+} and Tb^{3+} as the hole traps, excellent X-ray charged afterglow phosphors were developed. The integrated TL intensity of the optimized $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ after exposure to X-rays is about 4.5 and 1.1 times higher than that of the state-of-the-art $\text{BaFBr}(\text{I}):\text{Eu}^{2+}$ storage phosphor. Intense initial $\text{Tb}^{3+} \ 4f \rightarrow 4f$ afterglow appears in $\text{NaYGeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ and more than 40 h afterglow is measurable in $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ after X-ray charging. We will show proof-of-concept anti-counterfeiting and X-ray imaging applications by using the developed afterglow phosphors and CsPbI_3 quantum dots. This work not only provides experimental evidence on the VRBE in the $\text{Bi}^{2+} \ ^2\text{P}_{1/2}$ ground state in NaYGeO_4 , but also shows how to design and develop good afterglow phosphors for anti-counterfeiting and X-ray imaging by deeply studying and controlling the trapping processes of charge carriers in bismuth and/or lanthanides doped inorganic compounds.

1. Introduction

Persistent luminescence, also called afterglow, is known as a self-sustained photon emission phenomenon where upon excitation source stimulation like X-rays, UV-light, or β irradiation, free electrons and holes are generated and stored in compounds. Stored charge carriers can be released at room temperature (RT) to continuously produce light emission from seconds to few days after stopping the excitation source [1–4]. Because of this unique feature, afterglow phosphors have many applications like in anti-counterfeiting[5], optical information storage [6], bacteria sterilization[7], 3D X-ray imaging[8], photocatalytic

reaction[2], AC-LED[9], and mechanoluminescence material exploration[10–14]. Although many inorganic compounds have been studied, $\text{SrAl}_2\text{O}_4:\text{Eu}^{2+},\text{Dy}^{3+}$ developed in 1993 is still the state-of-art afterglow phosphor due to its good afterglow intensity and duration time[15,16]. One reason for the slow development of afterglow phosphors is that many compounds were studied in a trial-and-error method and the charge carrier trapping processes are often not clear.

The charge carrier trapping and de-trapping processes are of interest in order to better unravel the afterglow mechanism and to explore and develop excellent afterglow phosphors. Generally, a persistent luminescence compound contains the compound lattice, the recombination

centre, the electron and hole capturing centres that could be compound intrinsic defect(s) or deliberately induced dopants like Cr^{3+} or lanthanides [17,18]. Relatively shallow traps (~ 0.65 eV) are needed to produce room temperature persistent luminescence. One expects that a persistent luminescence phosphor could be rationally explored and designed if the trap depths of electron and hole capturing centres can be controlled or engineered [19–21]. A good afterglow phosphor then may appear by further optimizing the compound synthesis processes.

The charge carrier trapping centres and depths can be designed by analyzing the locations of $4f^n$ ground states levels of lanthanides relative to compound bands [22,23]. A trivalent lanthanide can act as an electron capturing centre if the $4f^n$ ground state level of the corresponding divalent lanthanide is below the conduction band (CB) of the compound [15,24]. Here, the electron trapping depth is defined as the distance from the conduction band bottom to the ground state $4f^n$ level of divalent lanthanide. When the $4f^n$ ground state level locations of trivalent lanthanides are close above the valence band (VB) top, they can act as hole capturing centres [17,18,25]. The hole trapping depth can be estimated by the distance between the ground state $4f^n$ level and the top of the valence band. Apparently, the energy level locations of electron and hole capturing centres, the conduction band bottom, and the valence band top in compounds are crucial to the rational design of the electron and hole trap depths. In 2012, the so-called chemical shift model was established to construct a vacuum referred binding energy (VRBE) scheme by combining limited experimental spectroscopy data [22,26]. The VRBE scheme enables to compare the electron binding energy at the lanthanide $4f^n$ ground states levels, the conduction band bottom, and the valence band maximum in various inorganic compounds with respect to an identical reference energy [27].

Like lanthanides, bismuth can act as a charge carrier trapping centre in a compound [28]. The electronic configuration of the bismuth atom is $[\text{Xe}]4f^{14}5d^{10}6s^26p^3$. Various bismuth valence states can be formed when different outermost electrons of bismuth element are lost, such as Bi^+ (the outermost electrons are $6p^2$), Bi^{2+} ($6p^1$), Bi^{3+} ($6s^2$), and Bi^{4+} ($6s^1$) [29]. In compounds trivalent bismuth can act both as an electron capturing centre and a hole trapping centre. In ref. [30], the dual role of Bi^{3+} as electron and hole traps was first tested in La-, Y-, and LuPO_4 compounds. However, there is no direct evidence on the VRBE in the $\text{Bi}^{2+} 2p_{1/2}$ ground states in LaPO_4 and LuPO_4 . In ref. [31], we reported the VRBE diagrams of $\text{ARE}(\text{Si,Ge})\text{O}_4$ ($A = \text{Li, Na; RE} = \text{Y, Lu}$) family compounds. The real VRBE in the $\text{Bi}^{2+} 2p_{1/2}$ ground states still remained

unclear. The study on VRBE in the Bi^{2+} level locations will help to unravel the charge carrier trapping processes and the rational design of new Bi^{3+} doped afterglow phosphors.

We have studied in ref. [31] the AREGeO_4 ($A = \text{Li, Na; RE} = \text{Y, Lu}$) solid solution family of compounds doped with Bi^{3+} , Eu^{3+} , Tb^{3+} , and Pr^{3+} doping. That study resulted in the VRBE scheme of Fig. 1 that was also published in ref. [31]. The combination $\text{Bi}^{3+}\text{-Eu}^{3+}$ was also studied in ref. [31]. The new content in this work is that the combination $\text{Bi}^{3+}\text{-Nd}^{3+}$, $\text{Bi}^{3+}\text{-Tb}^{3+}$, and $\text{Bi}^{3+}\text{-Pr}^{3+}$ in NaYGeO_4 and the combination $\text{Bi}^{3+}\text{-Tb}^{3+}$ in $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4$ solid solutions was studied to explore afterglow phosphors after exposure to X-rays and 254 nm UV-light for anti-counterfeiting and X-ray imaging applications. The thermoluminescence (TL) glow curves of Bi^{3+} and $\text{Bi}^{3+}\text{-Eu}^{3+}$ codoped NaYGeO_4 were measured after charging by beta or gamma irradiation in ref. [31]. For X-ray imaging application, X-rays need to be used as the charging light source and the thermoluminescence properties of Bi^{3+} and/or lanthanide(s) doped NaYGeO_4 after X-ray charging is still unknown. Recently, Ou *et al.* reported $\text{NaLuF}_4\text{:Tb(15 mol\%)}@ \text{NaYF}_4$ nanocrystals for 3D X-ray imaging applications in ref. [1]. About 30 days Tb^{3+} afterglow can be measurable in $\text{NaLuF}_4\text{:Tb(15 mol\%)}@ \text{NaYF}_4$ after exposure to X-rays. We obtained the optimized $\text{NaLuF}_4\text{:Tb(15 mol\%)}@ \text{NaYF}_4$ nanocrystals produced by the authors from ref. [1]. To evaluate the X-rays induced afterglow performance in bismuth and/or lanthanides doped NaYGeO_4 , in this work we will compare the TL intensities of bismuth and/or lanthanides doped NaYGeO_4 to that of $\text{NaLuF}_4\text{:Tb(15 mol\%)}@ \text{NaYF}_4$ nanocrystals after X-ray charging. Xu *et al.* reported good lanthanide and/or Cr^{3+} doped transparent $(\text{Y, Ga})_3\text{Al}_2\text{Ga}_3\text{O}_{12}$ garnet afterglow ceramics after UV-light charging [32–34]. We obtained these optimized afterglow garnet ceramics from Dr. Jian Xu. We will compare the afterglow intensities of bismuth and/or lanthanides doped NaYGeO_4 developed in this work after 254 nm UV-light charging to that of lanthanide and/or Cr^{3+} doped transparent $(\text{Y, Ga})_3\text{Al}_2\text{Ga}_3\text{O}_{12}$ garnet afterglow ceramics produced by Dr. Xu in refs. [33,34].

Fig. 1(a) predicts that, like Bi^{3+} , Tb^{3+} and Pr^{3+} can also act as hole capturing centres in NaYGeO_4 . One then can further verify the $\text{Bi}^{2+} 2p_{1/2}$ ground state location by studying the thermoluminescence properties of Bi^{3+} and/or Ln^{3+} co-doped NaYGeO_4 . Assuming that there is an electron de-trapping process from Bi^{2+} , recombination of the electron from Bi^{2+} with holes trapped at Bi^{4+} , Tb^{4+} , or Pr^{4+} should lead to a same TL glow curve but with characteristic emission from Bi^{3+} , Tb^{3+} , or Pr^{3+} . In this work, we will evidence the electron liberation process from Bi^{2+} by

Fig. 1. (a) Vacuum referred binding energy (VRBE) diagram for NaYGeO_4 compound with the Tb^{3+} , Pr^{3+} , Nd^{3+} , Bi^{3+} , and Bi^{2+} energy level locations. (b) Stacked VRBE diagram for NaYGeO_4 and NaLuGeO_4 .

deeply studying the Bi^{3+} and/or lanthanides doped NaYGeO_4 . Results show that Bi^{3+} can act as a shallow electron trap, while Bi^{3+} , Tb^{3+} , and Pr^{3+} act as deep hole trapping and recombination centres in NaYGeO_4 . The trap depth of Bi^{3+} electron trapping centre is found to be about 0.64 eV by thermoluminescence study. The VRBE in the $\text{Bi}^{2+} \ ^2\text{P}_{1/2}$ ground state is then determined to -3.29 eV in NaYGeO_4 . The electron trap depth produced by the Bi^{3+} codopant in $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ solid solutions can be adjusted, by increasing x , resulting in conduction band engineering.

High X-ray storage capacity phosphors were developed in the optimized $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ by using Bi^{3+} as an electron trap and Bi^{3+} and Tb^{3+} as the hole trapping centres. The integrated TL intensity after X-ray charging for $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ is about 4.5 and 2.3 times higher than that of the state-of-the-art storage phosphor $\text{BaFBr}(\text{I}):\text{Eu}^{2+}$ and the optimized $\text{NaLuF}_4:\text{Tb}^{3+}$ afterglow phosphor in ref. [1]. The integrated TL intensity after X-ray charging for $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ is about 1.1, 1.1, and 1.9 times higher than that of the state-of-the-art $\text{BaFBr}(\text{I}):\text{Eu}^{2+}$, $\text{SrAl}_2\text{O}_4:\text{Eu}^{2+}, \text{Dy}^{3+}$, and the optimized $\text{NaLuF}_4:\text{Tb}^{3+}$ in ref. [1]. Particularly, the optimized $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ after 254 nm UV-light charging shows good initial afterglow intensity, which is higher than that of the optimized $\text{YAGG}:\text{Tb}^{3+}, \text{Cr}^{3+}$ transparent afterglow ceramic in the first ~ 10 s. We will show proof-of-concept color tailoring for anti-counterfeiting applications by combining perovskite CsPbI_3 quantum dots (QD) with finely designed charge carriers in NaYGeO_4 where Bi^{3+} acts as an electron trap while both Tb^{3+} and Pr^{3+} act as the hole trapping and recombination centres. Proof-of-concept X-ray storage application was demonstrated in the optimized $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ phosphors and silicon gel based flexible X-ray imaging films.

2. Experimental

All starting chemicals were purchased from Shanghai Aladdin chemical company and utilized without further treatment. The phosphor compounds were prepared via a typical conventional high temperature solid state reaction method. The appropriate stoichiometric mixture of Bi_2O_3 (99.99%), Na_2CO_3 (99.99%), Y_2O_3 (99.99%), Lu_2O_3 (99.99%), GeO_2 (99.99%), and rare earth oxides with high purity of 4 N (99.99%) was ground and mixed for ~ 15 min in agate mortar with the help of acetone. Then, the mixture was carefully placed in a covered alumina crucible and heated at 1200°C for 6 h in a tube furnace under ambient atmosphere. The used heating rate for the furnace is $5^\circ\text{C}/\text{min}$. Finally, the synthesized compounds were cooled to room temperature (RT) and ground and milled well before further measurements. The afterglow properties of $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ have been optimized by adjusting synthesis temperature and the concentration of dopants.

To compare afterglow performance of the optimized $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$, lanthanide and/or Cr^{3+} doped transparent garnet afterglow ceramics were synthesized by a high temperature solid state reaction in vacuum [33]. The detailed ceramic compositions are $(\text{Gd}_{0.995}\text{Ce}_{0.005})_3\text{Al}_{1.9995}\text{Ga}_3\text{O}_{12}:0.0005\text{Cr}^{3+}$ ($\text{GAGG}:\text{Ce}^{3+}, \text{Cr}^{3+}$), $(\text{Y}_{0.995}\text{Ce}_{0.005})_3\text{Al}_{1.999}\text{Ga}_3\text{O}_{12}:0.001\text{Cr}$ ($\text{YAGG}:\text{Ce}^{3+}, \text{Cr}^{3+}$), $\text{Y}_{2.97}\text{Al}_{1.999}\text{Ga}_3\text{O}_{12}:0.03\text{Tb}^{3+}, 0.001\text{Cr}^{3+}$ ($\text{YAGG}:\text{Tb}^{3+}, \text{Cr}^{3+}$), $\text{Y}_{2.985}\text{Al}_{1.999}\text{Ga}_3\text{O}_{12}:0.015\text{Pr}^{3+}, 0.001\text{Cr}^{3+}$ ($\text{YAGG}:\text{Pr}^{3+}, \text{Cr}^{3+}$), and $\text{Gd}_{2.999}\text{Ga}_{4.9995}\text{O}_{12}:0.0005\text{Cr}^{3+}, 0.001\text{Eu}^{3+}$ ($\text{GGG}:\text{Cr}^{3+}, \text{Eu}^{3+}$) [35]. The above afterglow ceramics are produced by Dr. Xu in refs. [33,34] and are optimized samples that show intense afterglow after exposure to UV-light. To explore anti-counterfeiting application, CsPbI_3 quantum dot (QDs) was synthesized via a typical low-temperature solution reaction method [36,37]. Afterglow phosphors dispersed in flexible silicone films were explored to further demonstrate anti-counterfeiting application. The appropriate phosphors like $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ were first sifted by 200 mesh sieve and then were added into silicon gel (Sylgard 184, Dow Corning) and mixed well to generate a film on a smooth glass substrate.

Then, the film was placed at 60°C in vacuum for 4 h.

The crystal structures of synthesized compounds were checked using a Rigaku Smar/SmartLa X-ray diffraction system equipped with Cu K α ($\lambda = 0.15405$ nm) X-ray tube at 40 kV and 30 mA. The scanning electron microscope (SEM) photographs and energy dispersive X-ray spectroscopy (EDX) mapping were recorded by a JEOL JSM-7610FPlus scanning electron microscope. Photoluminescence emission (PL), PL excitation (PLE) spectra, afterglow spectra, and room temperature (RT) *iso*-thermal decay curves were measured using a FLS920 spectrometer (Edinburgh), which contains a 450 W Xe900 continuous xenon lamp, a monochromator, and a single photon counting photomultiplier (Hamamatsu, R928P). The red-sensitive R928P photomultiplier works at -20°C and has high quantum efficiency from 200 nm to 870 nm. The PL and PLE spectra are corrected by the wavelength-dependent excitation intensity of the xenon arc lamp.

Low-temperature thermoluminescence (LTTL) measurements between 100 K and 600 K and above RT thermoluminescence (TL) measurements were recorded by a facility that contains a thermostat, a R928P photomultiplier, a UV/vis spectrometer (Ocean Optics, model QE65Pro), a Hg lamp (254 nm), and a X-ray tube. Prior to all the LTTL and TL measurements, the samples were heated to 723 K for 5 mins to empty all trapped charge carriers and then cooled to initial temperature at 100 K for LTTL recording or at 300 K for above RT TL recording. For the LTTL measurements, phosphor powders were pressed into a pill and placed on the heater of the thermostat using silver paint in vacuum. For the 3D TL emission (TLEM) plot, the thermally stimulated emission was recorded by a QE65Pro detector. For optically stimulated luminescence measurements, the excitation light sources of daylight, 850 nm laser, 656 nm laser, 396 nm LED, 365 nm UV light, and white LED (WLED) are used. A sample is first charged by X-ray or 254 nm UV-light and then illuminated by different light stimulation with different duration time, and then a TL glow curve is recorded.

To study charge carrier trapping processes, thermoluminescence excitation (TLE) spectra were measured employing the FLS920 spectrometer (Edinburgh). Different energy photon with the wavelength from 200 nm to 300 nm was used to charge the Bi^{3+} and/or lanthanides doped NaYGeO_4 afterglow phosphors for a duration of 60 s and then RT *iso*-thermal decay curves were recorded for 60 s by monitoring the wavelength at 549 nm for Tb^{3+} emission and at 402 nm for Bi^{3+} emission. For the TLE measurements we recorded the afterglow decay for a duration of 60 s because the afterglow intensities are relatively intense during the first 60 s after switching off the excitation light. Integrated RT *iso*-thermal decay intensity for 60 s was corrected by the wavelength-dependent excitation intensity of the xenon arc lamp. A so-called TL excitation (TLE) plot like in Fig. 9 (b) is constructed by displaying the corrected *iso*-thermal decay intensity as a function of charging wavelength.

3. Results

3.1. X-ray diffraction and photoluminescence spectroscopy

High purity compounds are required for studying the charge carrier trapping processes. We therefore measured the X-ray diffraction patterns (XRD) for the as-synthesized Bi^{3+} and/or lanthanide doped NaYGeO_4 , which are shown in Fig. 2(a). All prepared samples have single phase and their XRD patterns match well with NaYGeO_4 reference card (No. PDF#88-1177). The dopants are assumed to substitute the Y^{3+} sites in the crystal. One expects a slight shift of the XRD pattern near 32° towards a lower angle after Bi^{3+} and/or lanthanides codoping since the radius of Y^{3+} ($r = 0.9$ Å, CN = 6) is smaller than that of Bi^{3+} ($r = 1.03$ Å, CN = 6), Tb^{3+} ($r = 0.92$ Å, CN = 6), and Nd^{3+} ($r = 0.98$ Å, CN = 6). Compared with the XRD pattern of NaYGeO_4 host, Fig. 2(b) shows that this expected shift does not appear. Possibly the concentration of doped bismuth and lanthanides is too low and then the increase of cell volume of NaYGeO_4 is too small.

Fig. 2. (a) XRD patterns for the as-synthesized compounds of Bi³⁺ and/or lanthanide doped NaYGeO₄ and NaYGeO₄ host. (b) Detailed XRD patterns in the range from 30° to 33°.

In order to understand the complex charge carrier trapping processes in bismuth and/or lanthanides doped NaYGeO₄, we need to first know the fundamental luminescence properties of bismuth and/or lanthanides doped NaYGeO₄. We therefore first measured the photoluminescence excitation spectra, emission spectra, and afterglow spectra for the bismuth and/or lanthanides doped NaYGeO₄ which are shown in Fig. 3. Fig. 3(a) shows the PLE and PL spectra of NaYGeO₄:0.004Bi³⁺. A similar spectrum recorded at 10 K and extending to the vacuum ultra violet range was published in ref.[31]. Characteristic Bi³⁺ D-band excitation near 238 nm and Bi³⁺ A-bands near 298 nm and 310 nm due to Jahn-Teller splitting of the Bi³⁺ ³P₁ excited state appear as observed previously in ref.[31]. Fig. 3 in ref. [38] shows that the band at 43000 cm⁻¹ is not from an intrinsic Bi³⁺ excitation which confirms the assignment as D-band in NaLuGeO₄ and NaYGeO₄. Upon 298 nm excitation, NaYGeO₄:0.004Bi³⁺ shows a broad emission band peaked at about 402 nm, which is due to the Bi³⁺ ³P₁→¹S₀ transition (A-band), see also ref. [31]. Charged by Bi³⁺ D-band excitation with a Hg lamp, Bi³⁺ ³P₁→¹S₀ blue afterglow emerges in Fig. 3(b). After co-doping Nd³⁺ into NaYGeO₄:0.004Bi³⁺, similar PLE and PL spectra appear in Fig. 3(c) as in Fig. 3(a). Fig. 3 (d) shows the RT iso-thermal decay curves of NaYGeO₄:0.004Bi³⁺, 0.005Nd³⁺ after Hg lamp charging. In addition to the Bi³⁺ afterglow as observed in NaYGeO₄:0.004Bi³⁺ in Fig. 3(b), new Nd³⁺ 1062 nm infrared persistent luminescence appears in NaYGeO₄:0.004Bi³⁺, 0.005Nd³⁺ in Fig. 3(d).

Fig. 3(e) and Fig. S3 shows the PLE and PL spectra for NaYGeO₄:0.005Tb³⁺. Like in ref.[31], the PLE peaks near 248 and 286 nm are assigned to Tb³⁺ 4f → 5d transitions, while the fitted PLE peak near 262 nm is assigned to the Intervalence Charge Transfer Band (IVCT), which is induced by electron transfer from the Tb³⁺ 4f ground state to the conduction band (CB), i.e., Tb³⁺→CB IVCT. In ref.[31] an excitation band peaked near 236 nm was observed in the excitation spectrum of NaYGeO₄:0.01Tb³⁺ in Fig. S5(h). It is absent in Fig. 3(e).

The observed 236 nm excitation band in ref. [31] could be due to host-related defect(s). After exposure to 254 nm UV-light, during more than 25 min typical Tb³⁺ 4f → 4f afterglow appears in Fig. 3 (f) and Fig. S4.

Fig. 3(g) shows the PLE and PL spectra of NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺. Upon 254 nm excitation, the emission spectrum is mainly composed of characteristic Tb³⁺ 4f-4f transitions. Monitored at the Tb³⁺ 549 nm typical emission, not only Tb³⁺ 4f → 5d excitation band peaked near 253 nm and Tb³⁺→CB IVCT band peaked near 260 nm but also Bi³⁺ excitation A-band appear in the excitation spectrum. It suggests that there is an energy transfer process from Bi³⁺ to Tb³⁺. Compared with NaYGeO₄:0.005Tb³⁺ in Fig. 3(f), about 10 times stronger Tb³⁺ afterglow emerges in the Bi³⁺, Tb³⁺-codoped NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺ in Fig. 3(h) and 3(i). Fig. 3(j) further demonstrates that the Tb³⁺ afterglow at 549 nm is much stronger than the 402 nm afterglow in NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺.

3.2. Evidencing the electron liberation process from Bi²⁺

To understand the afterglow observed in Fig. 3 and to discuss the charge carrier trapping and de-trapping processes in bismuth and/or lanthanides doped NaYGeO₄, low-temperature thermoluminescence emission (TLEM) spectra were recorded after exposure to X-rays at 100 K. Fig. 4(a) shows the TLEM plot for NaYGeO₄:0.005Tb³⁺. TL glow peaks near 161, 219, and 284 K with characteristic Tb³⁺ 4f → 4f emission appear in NaYGeO₄:0.005Tb³⁺. Fig. 4(b) shows the TLEM plot for NaYGeO₄:0.004Bi³⁺. A strong TL glow peak near 270 K with characteristic Bi³⁺ A-band emission emerges in NaYGeO₄:0.004Bi³⁺. Particularly, a similar TL glow peak near 272 K appears in NaYGeO₄:0.004Bi³⁺, 0.005Tb³⁺ in Fig. 4(c) and in NaYGeO₄:0.004Bi³⁺, 0.005Pr³⁺ in Fig. 4(d) where the thermally stimulated emission is from Tb³⁺ or Pr³⁺ typical 4f → 4f emission rather than Bi³⁺ A-band emission. The TL glow peak near ~ 270 K is absent in NaYGeO₄:0.005Tb³⁺ in Fig. 4(a) but

Fig. 3. Photoluminescence excitation (PLE) and emission (PL) spectra, RT iso-thermal decay curve and afterglow spectra as a function of time after exposure to 5 min 254 nm UV-light charging for (a)-(b) NaYGeO₄:0.004Bi³⁺, (c)-(d) NaYGeO₄:0.004Bi³⁺, 0.005Nd³⁺, (e)-(f) NaYGeO₄:0.005Tb³⁺, and (g)-(j) the optimized afterglow phosphor NaYGeO₄:0.003Bi³⁺, 0.008 Tb³⁺. The insets in (b), (d), (f), and (h) are the afterglow photographs after 254 nm UV-light illumination in the dark.

Fig. 4. Low-temperature thermoluminescence (TL) emission spectra for (a) NaYGeO₄:0.005Tb³⁺, (b) NaYGeO₄:0.004Bi³⁺, (c) NaYGeO₄:0.004Bi³⁺, 0.005Tb³⁺, and (d) NaYGeO₄:0.004Bi³⁺, 0.005Pr³⁺ after exposure to X-ray charging at 100 K. The used heating rate is 0.2 K/s in (a)–(d).

emerges in Fig. 4(b)–(d) when Bi³⁺ is present in NaYGeO₄. We will attribute the 270 K TL glow peak to electron liberation from Bi²⁺ and recombination with holes at Bi⁴⁺ in Fig. 4(b), at Tb⁴⁺ in Fig. 4(c), and at Pr⁴⁺ in Fig. 4(d) to generate characteristic Bi³⁺ ³P₁ → ¹S₀ emission and Tb³⁺ and Pr³⁺ 4f → 4f emissions.

In ref. [31] both the VRBE diagrams of NaYGeO₄ and NaLuGeO₄ have been presented. The VRBE at the conduction band bottom of NaLuGeO₄ is about 0.1 eV lower than that of NaYGeO₄. Assuming that the VRBEs at the Bi²⁺ and Eu²⁺ ground state level locations remain stationary, one expects that the electron trap depths of Bi³⁺ and Eu³⁺ will increase in NaLu_{1-x}Y_xGeO₄ solid solutions with increasing x. This prediction has been verified in NaLu_{1-x}Y_xGeO₄:0.01Bi³⁺, 0.001Eu³⁺ and in NaLu_{1-x}Y_xGeO₄:0.01Bi³⁺ that has been published in ref.[31]. Fig. 5(a) reproduces the low-temperature TL glow curves for NaLu_{1-x}Y_xGeO₄:0.01Bi³⁺ after beta irradiation. Fig. 1 predicts that Bi³⁺ can act as an electron trap, while Tb³⁺ can act as a hole trapping and recombination centre. Therefore, we made NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺, 0.008Tb³⁺ solid solutions to demonstrate the electron liberation from Bi²⁺ and to explore Tb³⁺ afterglow phosphors for anti-counterfeiting and X-ray imaging applications. Fig. 5(b) and S6(a) show the normalized and unnormalized low-temperature thermoluminescence glow curves for NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺, 0.008Tb³⁺ solid solutions after exposure to X-rays at 93 K. Like in Fig. 5(a), the TL glow peak named Bi²⁺ peak gradually shifts from ~233 K for x = 0 to ~283 K for x = 1 with increasing x in NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺, 0.008Tb³⁺. This TL glow peak shifting will be assigned to the increased electron trap depth of Bi³⁺ when increasing x in NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺, 0.008Tb³⁺. Table 1 lists the TL results and calculated electron trapping depths for the Bi²⁺ TL glow peaks for NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺, 0.008Tb³⁺ based on a first-order TL recombination

kinetics and assuming zero distribution in Bi²⁺ trap depth. The reported Bi²⁺ trapping depths and the frequency factors for NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺, 0.008Tb³⁺ then should be treated as indicative. Assuming a typical fixed frequency factor of $1 \times 10^{13} \text{ s}^{-1}$ for NaLu_{1-x}Y_xGeO₄[23], the Bi²⁺ trapping depth in NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺, 0.008Tb³⁺ can be determined by a first-order TL recombination kinetics to 0.64, 0.68, 0.71, 0.75, and 0.78 eV for x = 0–1. These values are larger than that in column 4 of Table 1 because a larger frequency factor of $1 \times 10^{13} \text{ s}^{-1}$ is used.

We know from combining experimental results with empirical models that the Bi²⁺ ground state level should be located around -3.5 ± 0.5 eV in inorganic compounds as also indicated for NaYGeO₄ in the scheme of Fig. 1. Similarly we know from Lyu and Dorenbos (T. Lyu, P. Dorenbos, Chem. Mater. 32 (2020) 1192.)[31] that compounds like LiLuSiO₄, LiYSiO₄, LiLuGeO₄, and LiYGeO₄ all have the VB-top near -9.5 eV. One can combine that knowledge with studies by Qiao et al. (Zheng Qiao, Xuesong Wang, Chen Heng, Wei Jin, Lixin Ning, Inorg. Chem. 60 (2021) 16604.)[39] in 2021 on LiREGeO₄ (RE = Sc, Y, Lu) where the Bi²⁺ ground state is computed about 6 eV above the VB-top. This brings the Bi²⁺ ground state indeed near -3.5 eV. One, if not the first, direct computation of the VRBE in the Bi²⁺ ground state was by Lou et al. (Bibo Lou, Jun Wen, Lixin Ning, Min Yin, Chong-Geng Ma, Chang-Kui Duan, Phys. Rev. B 104 (2021) 115101)[40]. In the REAlO₃ (RE = La, Gd, Y), LaGaO₃, and LaInO₃ perovskites the Bi²⁺ ground state is always computed near -4 eV. Considering the above, we do expect Bi³⁺ to act as a 0.85 ± 0.5 eV deep electron trap in NaYGeO₄. The observation of an intense glow peak near ~272 K at β = 0.2 K/s in Fig. 4 and near 283 K at β = 1 K/s in Fig. 5(b) due to an electron releasing trapping center, strongly suggests that this peak is due to electron release from Bi²⁺ when Bi³⁺ is present in the compound.

Fig. 5. TL glow curves for (a) $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4:0.01\text{Bi}^{3+}$ after beta irradiation and (b)-(c) $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ after X-rays or 254 nm UV-light charging measured at $\beta = 1$ K/s. (d) RT isothermal decay curves and (e) afterglow photographs for $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ after exposure to 254 nm UV-light. The Tb^{3+} emission was monitored and the afterglow was corrected by sample mass and irradiation time. The data in (a) was reproduced from ref. [31]. The Bi^{3+} emission was monitored in (a) and the Tb^{3+} emissions were monitored in (b).

Table 1

TL results for $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ providing the frequency factor s (s^{-1}) and the electron trap depths E (eV) for the Bi^{2+} glow peaks (T_m). The frequency factors for $x = 0-0.75$ were obtained from ref. [31] and the frequency factor for $x = 1$ was obtained from this work.

x	s	$T_m \text{ Bi}^{2+}$ (K)	$\text{Bi } E$ (eV)
0	9.23×10^9	233	0.50
0.25	3.73×10^9	245	0.51
0.50	3.16×10^9	256	0.54
0.75	9.73×10^9	271	0.59
1	1.23×10^{10}	283	0.63

To evaluate afterglow properties, we also measured above RT TL glow curves for $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ after 254 nm UV-light charging as shown in Fig. 5(c) and after X-ray charging for $x = 1$ in Fig. S6(b). Fig. 5(c) shows that the TL glow peak near 311 K appears to shift towards a higher temperature and the TL intensity decreases with decreasing x . This is because that the RT TL glow curves in Fig. 5(c) are in the tail of the glow peak that shifts from ~ 233 K to ~ 283 K in Fig. 5(b) and there is a distribution in Bi^{2+} trapping depths in $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$. With the above RT TL glow curves in Fig. 5(c) then only the deepest Bi^{2+} traps contribute to the 311 K TL glow

peak.

To study the Bi^{2+} trap distribution, we used the peak cleaning technique for $x = 1$ sample ($\text{NaYGeO}_4:0.003\text{Bi}^{3+},0.008 \text{ Tb}^{3+}$) [19,41]. After exposure to 254 nm UV-light for a duration of 20 s at RT, the $x = 1$ sample was rapidly heated at a heating rate of 5 K/s to the peak clean temperature (T_{clean}) and maintained at that T_{clean} for 60 s. The sample was then cooled to RT and a TL glow curve was recorded at a heating rate of 1 K/s. Fig. S6(c) demonstrates that the TL glow peak near RT shifted towards a higher temperature and the TL intensity decreased with increasing T_{clean} . This indicates that there is a trap depth distribution for the sample with $x = 1$, and the increase in TL glow peak is because of the fact that the electrons captured in the shallow Bi^{2+} traps have been released at T_{clean} and only the electrons at deeper Bi^{2+} traps remain occupied. Fig. S6(b) compares the TL glow curves of the $x = 1$ sample charged with X-rays and 254 nm UV-light with a same heating rate of 1 K/s. The TL glow peak shifts from ~ 311 K to ~ 340 K when the charging is changed from 254 nm UV-light to X-rays. Apparently, stable and deeper Bi^{2+} traps capture more efficiently free charge carriers during X-ray exposure and then higher TL glow peak (T_m) appears upon X-ray charging. Another possible reason is that with optical excitation the liberated electron is trapped relatively close to the hole trapping center. The electron does not need to go through the CB in order to recombine with the hole. Effectively this will lower the energy barrier

for detrapping and thus a lower temperature glow peak. With X-ray excitation separate hole trap and electron trap are created and recombination is realized via the CB. The same applies for NaYGeO₄:yBi³⁺,0.008 Tb³⁺ (y = 0.001–0.012) as shown in Fig. S13(b)–S13(c) and the lanthanide and/or bismuth doped NaYGeO₄ in Fig. 7 (b) and 7(c).

Fig. 5 (d)–(e) shows the RT isothermal decay curves and afterglow photographs for NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺,0.008 Tb³⁺ after exposure to 254 nm UV-light. The Tb³⁺ afterglow increases with increasing x in NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺,0.008 Tb³⁺.

3.3. Designing afterglow phosphor by using electron release from Bi²⁺

To unravel the nature of the recombination centres and to design afterglow phosphors, we measured above RT TL emission (TLEM) spectra for the bismuth and/or lanthanide(s) doped NaYGeO₄ as shown in Fig. 6. TL glow peaks near 340, 451 and 579 K with typical Tb³⁺ 4f → 4f emission appear in NaYGeO₄:0.005Tb³⁺ in Fig. 6(a). For NaYGeO₄:0.004Bi³⁺ in Fig. 6(b), TL glow peaks near 335 K and 418 K with characteristic Bi³⁺ A-band emission emerge. TL glow peaks near 373 K and 446 K were observed in NaYGeO₄:0.01Bi³⁺ in Fig. 6(a) in ref. [31] where there was about 20 min time between γ-ray charging and the start of the TL-readout. It means that the stored charge carriers in the shallower traps are already de-trapped before TL-readout and the 335 K TL glow peak near RT will shift towards a higher temperature 373 K. The 418 and 446 K TL glow peaks are assigned to electron liberation from different host-related intrinsic defects in NaYGeO₄ and recombination with holes captured at Bi⁴⁺. Compared with NaYGeO₄:0.004Bi³⁺ in Fig. 6(b), similar TL glow peaks also appear in NaYGeO₄:0.004Bi³⁺,0.005Nd³⁺ in Fig. 6(c) where the recombination

emission comes from both typical Bi³⁺ A-band and Nd³⁺ infrared 4f → 4f transitions. Fig. 6(d) shows the TLEM plot for the optimized NaYGeO₄:0.003Bi³⁺,0.008 Tb³⁺. Strong TL glow peaks near 349 and 484 K with typical Tb³⁺ 4f-4f emission are observed with the TL intensity about 10 times higher than that of other compounds in Fig. 6(a)–(c).

To compare the charge carrier storage capacity properties of the prepared lanthanide and/or bismuth doped NaYGeO₄, X-ray excited emission as a function of time, TL glow curves after exposure to X-rays and 254 nm UV-light were measured and shown in Fig. 7 (a)–7(c). Fig. 7 (a) shows the X-ray excited emission intensities for bismuth and/or lanthanide(s) doped NaYGeO₄, commercial Al₂O₃:C single chip, SrAl₂O₄:Eu²⁺,Dy³⁺, and BaFBr(I):Eu²⁺, and the NaLuF₄:Tb³⁺ from ref. [1]. In this experiment we switched on the X-ray beam and continuously monitored all the emission intensity from the sample via a photomultiplier (PMT). A SCHOTT BG-39 filter from about 300 to 800 nm was placed between the PMT tube and the sample. The ratios of integrated X-ray excited emission intensities from 0 to 200 s of bismuth and/or lanthanide(s) doped NaYGeO₄, Al₂O₃:C, SrAl₂O₄:Eu²⁺,Dy³⁺, and NaLuF₄:Tb³⁺ to that of BaFBr(I):Eu²⁺ are shown in the legend in Fig. 7 (a). The integrated X-ray excited emission intensity of NaLuF₄:Tb³⁺ from ref. [1] is higher than that of other lanthanide and/or bismuth doped NaYGeO₄. It means that more X-ray photons are converted into visible light. NaYGeO₄:0.004Bi³⁺ shows the strongest X-ray excited emission intensity among the bismuth and/or lanthanide(s) doped NaYGeO₄.

The afterglow phosphors were charged by both X-rays and 254 nm UV-light for X-ray imaging application. Fig. 7(b) shows the TL glow curves of bismuth and/or lanthanide(s) doped NaYGeO₄ after X-ray charging. The ratios of integrated TL intensities between 305 and 723 K

Fig. 6. Thermoluminescence (TL) emission plots for (a) NaYGeO₄:0.005Tb³⁺, (b) NaYGeO₄:0.004Bi³⁺, (c) NaYGeO₄:0.004Bi³⁺,0.005Nd³⁺, and (d) NaYGeO₄:0.003Bi³⁺,0.008 Tb³⁺ after Hg lamp (254 nm) illumination for 5 min. The used heating rate is 1 K/s.

Fig. 7. (a) X-ray excited emission as a function of time, TL glow curves at $\beta = 1$ K/s for lanthanide and/or Bi³⁺ doped NaYGeO₄, NaLuF₄:Tb³⁺ from ref. [1], and the state-of-the-art BaFBr(I):Eu²⁺, SrAl₂O₄:Eu²⁺, Dy³⁺, and Al₂O₃:C single crystal chip after exposure to (b) 1.5 W X-rays and (c) 254 nm UV-light. (d) a comparison of afterglow photographs after UV-light charging. (e) variable heating rate plot for NaYGeO₄:0.004Bi³⁺, 0.005Nd³⁺ after X-ray charging. The used heating rates were 0.2, 0.4, 0.8, 1.6, 3, 4.5, and 6.4 K/s.

of bismuth and/or lanthanide(s) doped NaYGeO₄ to that of BaFBr(I):Eu²⁺, Al₂O₃:C, and SrAl₂O₄:Eu²⁺, Dy³⁺ are shown in the legend of Fig. 7 (b). The TL intensity of NaYGeO₄:0.004Bi³⁺ and the optimized NaYGeO₄:0.003Bi³⁺, 0.008 Tb³⁺ is about 4.5 and 1.1 times higher than that of the state-of-the-art BaFBr(I):Eu²⁺ after X-ray charging. Like in NaYGeO₄:0.01Bi³⁺ in Fig. 7(e) in ref. [31], the TL glow peak near 349 K in Bi³⁺-codoped NaYGeO₄ in Fig. 7(b) will be assigned to electron release from Bi²⁺ and recombination with holes captured at Bi⁴⁺ and Tb⁴⁺ generating characteristic Bi³⁺ ³P₁ → ¹S₀ emission and Tb³⁺ 4f → 4f emissions. Other common TL glow peaks near 474, 510, and 590 K in Fig. 7(b) will be assigned to electron liberation from host-related intrinsic defect(s).

Fig. 7(c) shows the TL glow curves for bismuth and/or lanthanide(s) doped NaYGeO₄ after 254 nm UV-light charging. The ratios of the integrated intensities between 305 and 723 K of bismuth and/or lanthanide(s) doped NaYGeO₄ to that of BaFBr(I):Eu²⁺ and Al₂O₃:C are shown in legend of Fig. 7(c). The integrated TL intensity of the optimized NaYGeO₄:0.003Bi³⁺, 0.008 Tb³⁺ after 254 nm UV-light charging is strongest and is about 31 times higher than that of BaFBr(I):Eu²⁺. It means that strong Tb³⁺ afterglow appears in the optimized NaYGeO₄:0.003Bi³⁺, 0.008 Tb³⁺ after 254 nm UV-light charging, which is evidenced by the afterglow photographs in Fig. 7(d). A common TL glow peak near 327 K was observed in Bi³⁺-codoped NaYGeO₄.

There is a common low temperature TL glow peak near 349 K in Fig. 7(b) and near 327 K in Fig. 7(c) whenever Bi³⁺ is present. To analyse this TL peak further we studied the NaYGeO₄:0.004Bi³⁺, 0.005Nd³⁺ sample in more detail because it contains very low Bi³⁺ and Nd³⁺ concentration. The trapping depth (E) for NaYGeO₄:0.004Bi³⁺, 0.005Nd³⁺ was derived by using a typical variable heating rate plot and formula [17,42,43]:

$$\ln\left(\frac{T_m^2}{\beta}\right) = \frac{E}{kT_m} + \ln\left(\frac{E}{ks}\right) \quad (1)$$

where k is the Boltzmann constant (8.62×10^{-5} eV/K), T_m is the TL glow peak, s is the frequency factor (s^{-1}), and β means the used heating rate that can adjust from 0.2 to 6.4 K/s as shown in Fig. S10. Fig. 7(e) gives the variable heating rate plot for NaYGeO₄:0.004Bi³⁺, 0.005Nd³⁺ that determines the trap depth to be 0.78 eV and the frequency factor to be $1.23 \times 10^{10} s^{-1}$ which is also listed in Table 1. Since the concentration of doped Bi³⁺ and Nd³⁺ is very low, it was assumed that the above obtained frequency factor s also applies to other bismuth and/or lanthanides doped NaYGeO₄.

Assuming a first-order TL-recombination kinetic process, the trap depth of the Bi²⁺ TL glow peak near 272 K in NaYGeO₄:0.004Bi³⁺ in Fig. 4(b), in NaYGeO₄:0.004Bi³⁺, 0.005Tb³⁺ in Fig. 4(c), and in NaYGeO₄:0.004Bi³⁺, 0.005Pr³⁺ in 4(d) can be estimated by solving Eq.

(1) with the known temperature T_m at the maximum of the TL glow curve, i.e., $T_m = 272$ K, and utilizing $s = 1.23 \times 10^{10} \text{ s}^{-1}$ and $\beta = 0.2 \text{ K/s}$. The trap depth for Bi^{2+} TL glow peak near 272 K is then calculated to be 0.64 eV.

Fig. 8 shows the isothermal decay curves of lanthanides and/or bismuth doped NaYGeO_4 after exposure to 254 nm UV-light or X-rays at RT. Fig. 8(a) shows that bright Tb^{3+} initial afterglow appears in the optimized $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$, which is even higher than that of the state-of-the-art $\text{SrAl}_2\text{O}_4:\text{Eu}^{2+}, \text{Dy}^{3+}$ and the optimized YAGG: $\text{Tb}^{3+}, \text{Cr}^{3+}$ and YAGG: $\text{Ce}^{3+}, \text{Cr}^{3+}$ transparent ceramics. Fig. 8(b) further shows that more than 27.8 h afterglow is measurable in $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ after 254 nm UV-light charging. Fig. 8(c) and 8(d) show that bright Bi^{3+} initial afterglow emerges in $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$. More than 40 h afterglow is measurable in $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and the optimized $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ after X-ray charging, indicating good charge carrier storage capacity after exposure to X-rays.

To unravel the charge carrier trapping processes, Fig. 9(a) and Fig. S14 show the RT isothermal decay curves of $\text{NaYGeO}_4:0.005\text{Tb}^{3+}$, $\text{NaYGeO}_4:0.004\text{Bi}^{3+}, 0.005\text{Tb}^{3+}$, and $\text{NaYGeO}_4:0.004\text{Bi}^{3+}, 0.005\text{Nd}^{3+}$ after 60 s exposure to different energy photons. Fig. 9(b)–9(d) compares the TL excitation (TLE) curves with the PL excitation (PLE) spectra of $\text{NaYGeO}_4:0.004\text{Bi}^{3+}, 0.005\text{Nd}^{3+}$, $\text{NaYGeO}_4:0.005\text{Tb}^{3+}$, and $\text{NaYGeO}_4:0.004\text{Bi}^{3+}, 0.005\text{Tb}^{3+}$. For $\text{NaYGeO}_4:0.004\text{Bi}^{3+}, 0.005\text{Nd}^{3+}$, it can only be charged via the Bi^{3+} D-band. For $\text{NaYGeO}_4:0.005\text{Tb}^{3+}$ and $\text{NaYGeO}_4:0.004\text{Bi}^{3+}, 0.005\text{Tb}^{3+}$, they can be charged via $\text{Tb}^{3+} 4f \rightarrow 5d$ transition and $\text{Tb}^{3+} \rightarrow \text{CB IVCT}$.

3.4. Exploring anti-counterfeiting applications by using electron liberation from Bi^{2+}

For the development of advanced applications like anti-counterfeiting and X-ray imaging, the optically stimulated luminescence and stability after exposure to water for the developed storage phosphors have been evaluated. Fig. 10(a) first shows the TL glow curves of the optimized $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ after exposure to X-rays with 60–1200 s duration time. The inset in Fig. 10(a) shows that the integrated TL intensity appears to linearly increase with increasing the X-ray exposure time, indicating the potential application as a dosimeter for X-ray detection. The same applies for $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ in Fig. S11. Fig. 10(b) shows the TL glow curve of $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ after exposure to water for 1 h. The integrated TL intensity does not decrease, suggesting good chemical stability after exposure to moisture.

Optically stimulated luminescence properties are important for storage phosphors. Fig. 10(c) and S15–S16 shows the TL glow curves of $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ after 254 nm UV-light charging followed by different energy photon stimulation. The TL intensity decreases with 365, 396, 656, 850 nm, and WLED stimulation. It means that stored charge carriers can be removed by light stimulation. Fig. 10(d) further shows that the stored charge carriers are removed by an optically stimulated $\text{Tb}^{3+} 4f \rightarrow 4f$ emission process. The phosphor area stimulated by illumination light like 656 nm laser in Fig. 10(e3) has less stored charge carriers and then provides less Tb^{3+} afterglow. This feature can be used to display the text of “0, 1, and a” from the $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ based afterglow film in the dark in Fig. 10(g1)–(g3). The similar applies for $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ in Fig. S17–S18. For $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$, 58% of stored charge carriers

Fig. 8. (a)–(d) Isothermal decay curves of lanthanide and/or Bi^{3+} doped NaYGeO_4 , $\text{NaLuF}_4:\text{Tb}^{3+}$, the state-of-the-art $\text{BaFBr}(\text{I}):\text{Eu}^{2+}$, $\text{SrAl}_2\text{O}_4:\text{Eu}^{2+}, \text{Dy}^{3+}$, $\text{Al}_2\text{O}_3:\text{C}$ single crystal chip, and transparent garnet afterglow phosphors after exposure to X-ray charging or 254 nm UV-light charging at RT (303 K).

Fig. 9. (a) 2D contour plot of RT iso-thermal decay curves as a function of charging wavelength for NaYGeO₄:0.004Bi³⁺, 0.005Nd³⁺. A comparison of TL excitation (TLE) curves with the PL excitation (PLE) spectra for (b) NaYGeO₄:0.004Bi³⁺, 0.005Nd³⁺, (c) NaYGeO₄:0.005Tb³⁺, and (d) NaYGeO₄:0.004Bi³⁺, 0.005Tb³⁺. The PLE spectra of NaYGeO₄:0.005Tb³⁺ (λ_{em} = 545 nm) and NaYGeO₄:0.004Bi³⁺ (λ_{em} = 402 nm) recorded at RT are also given in (c)-(d).

can be removed by 20 s WLED stimulation in Fig. 10(c). Particularly, 93% of stored charge carriers in NaYGeO₄:0.004Bi³⁺ can be removed by 300 s WLED stimulation as shown in Fig. S17(b), implying good optically stimulated luminescence performance.

To explore anti-counterfeiting application by using the afterglow phenomenon, Fig. S19(a)-(h) shows the afterglow photographs and persistent luminescence spectra of the optimized NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺ and the optimized transparent garnet afterglow ceramics after exposure to 254 nm UV-light charging for 120 s. Strong afterglow photographs can be recorded for in the optimized NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺ powder sample after removing the 254 nm UV-light for 100 s. The 100 s afterglow intensity from NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺ is higher than that of the transparent garnet GAGG:Ce³⁺, Cr³⁺ and is comparable to that of YAGG:Tb³⁺, Cr³⁺ and YAGG:Pr³⁺, Cr³⁺ transparent garnet ceramics as shown in Fig. S19(g).

The optimized NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺ powder afterglow phosphor was dispersed into silicone gel to produce an afterglow film A in Fig. 11(a1)-(a5) and Fig. S20. A text of "HQU EXIT" is visible to the naked eye in the dark by selective charging the film A with a paper mask of "HQU EXIT" as demonstrated in Fig. 11(b1)-(b3). A QR code was printed on a sheet of paper as shown in Fig. 11(c1). Film A was first charged by 254 nm UV-light and then was placed underneath the sheet

of the paper. Because of the strong afterglow from the optimized NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺, the QR code is visible in the dark and can be easily scanned by a smart mobile phone to read out the hidden information of "This is a nice persistent luminescence material" as demonstrated in Fig. 11(c1)-(c3). Fig. S19(b1)-(b3) further demonstrates that film A has good ductility by stretching it with hands. Fig. S19(c1)-(c3) shows that the information of text of "HQU EXIT" can be stored in film A for more than 3 h and then can be read out by heating the film A to about ~ 353 K. Fig. S23(b1)-(b3) shows that afterglow film A can be stretched by hands, indicating the flexibility feature of this film.

To add new anti-counterfeiting features to film A, different concentration of CsPbI₃ quantum dots (QDs) was added to form film B in Fig. 12(b1) and film C in Fig. 12(c1). The CsPbI₃ QDs concentration in film C is much higher than that in film B and as a result, the photoluminescence color can be tailored from dark pink to bright orange red as shown in Fig. 12(b2) and 12(c2). Efficient energy transfer from the afterglow produced by NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺ to CsPbI₃ quantum dots is not observed. It means that efficient afterglow color change does not appear in film B and film C. An anti-counterfeiting application is supposed by using the highly efficient photoluminescence of CsPbI₃ QDs and the intense afterglow from NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺. This idea was testified and shown in Fig. 12(c3) and Fig. 12(c4) where the color of the text of "CsPbI₃ QD" can be changed from red under 254 nm

Fig. 10. TL glow curves measured at $\beta = 1$ K/s for NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺ after exposure to (a) X-ray with different duration time, (b) water for 1 h, and (c) 20 s optical stimulation by different excitation sources. (d) RT isothermal decay curves of NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺ after 850 nm laser stimulation. (e)-(g) Information display using the optically stimulated emission phenomenon in NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺.

UV-light illumination to green by stopping 254 nm UV-light illumination in the dark.

To further explore color tuning for anti-counterfeiting application, afterglow spectra were studied in bismuth and lanthanides co-doped NaYGeO₄. Fig. 1 predicts that, like Tb³⁺, Pr³⁺ also can act as a hole trapping and recombination centre but then with red emission. Fig. S25 (c)-S25(d) show the RT isothermal afterglow spectra and decay curves for NaYGeO₄:0.004Bi³⁺, 0.005Pr³⁺ after 254 nm UV-light charging. Characteristic Pr³⁺ 4f $\rightarrow$ 4f afterglow emissions appear. We therefore added Pr³⁺ in NaYGeO₄:Bi³⁺, Tb³⁺ to explore tailorable afterglow color. Fig. 13(a) shows the afterglow spectra of Bi³⁺ and/or lanthanides doped NaYGeO₄ after 254 nm UV-light charging. For NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺, 0.002Pr³⁺, Bi³⁺ ³P₁ $\rightarrow$ ¹S₀, both Tb³⁺ and Pr³⁺ typical 4f $\rightarrow$ 4f transitions appear in 300–675 nm range as evidenced in the afterglow spectrum in Fig. 13(a) and the photoluminescence emission, excitation spectra, RT isothermal afterglow and decay curves in Fig. S25.

White afterglow with color coordinate of (0.33, 0.35) appears in NaYGeO₄:0.003Bi³⁺, 0.008 Tb³⁺, 0.002Pr³⁺ after 254 nm UV-light charging as shown in Fig. 13(c) and Fig. S26. Fig. S27 shows the TL glow curves of NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺, 0.002Pr³⁺ after exposure to X-ray and 254 nm UV-light. TL glow peaks near 335 K in Fig. S27 (a) and near 314 K in Fig. S27(b) emerge, which result in the white afterglow. Film D in Fig. 13(d1) was made by using

NaYGeO₄:0.003Bi³⁺, 0.008 Tb³⁺, 0.002Pr³⁺ and silicone gel. A white afterglow film appears in the dark in Fig. 13(d3), which has a color coordinate of (0.30, 0.32) in Fig. 13(c). A text of "WHITE BiTbPr" appears in the dark in Fig. 13(d5) by selecting charging the film D with a paper mask in Fig. 13(d4). Fig. 13(d6) shows that about 40 h afterglow can be measurable in NaYGeO₄:0.003Bi³⁺, 0.008 Tb³⁺, 0.002Pr³⁺ after 254 nm UV-light charging.

3.5. Exploring X-ray imaging applications by using electron liberation from Bi²⁺

We explored the resolution of film A in Fig. S30(a1) for X-ray imaging. A paper mask with resolution from 0.25 mm to 10 mm was made by using a sheet of paper as shown in Fig. S30(a2). Film A was placed underneath the paper mask and can be selectively charged by 254 nm UV-light in Fig. S30(a3). The afterglow photographs in Fig. S30(a4)-(a6) show that a resolution of 0.25 mm (~ 4 lp/mm) can be obtained from film A upon 254 nm UV-light charging. Film E was made by using NaYGeO₄:0.004Bi³⁺ and silicone gel. Both films A and E have been testified for X-ray imaging as shown in Fig. 14. X-ray imaging photographs for objects of capsules with a metal spring in Fig. 14(a1)-(b4), an insect in Fig. S29(a1)-(a3), a chip in Fig. S29(a4)-(a6) are visible in the dark because of the thermally stimulated luminescence of Bi³⁺ ³P₁ $\rightarrow$ ¹S₀ transition in NaYGeO₄:0.004Bi³⁺ from film E and Tb³⁺ 4f $\rightarrow$ 4f

Fig. 11. Proof-of-concept anti-counterfeiting application by using $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ dispersed in silicone gel film A. Panels a1)–a5) show the preparation process of afterglow film A. Panels b1)–b3) and c1)–c3) show the application of the Tb^{3+} afterglow from film A to show the text of “HQU EXIT” and a QR code on a sheet of paper in the dark.

Fig. 12. Proof-of-concept anti-counterfeiting application by combining X-ray or UV-light charged Tb^{3+} afterglow and high PL quantum efficiency of CsPbI_3 quantum dots (QDs). a1) is $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ based film A. a2) shows the Tb^{3+} afterglow from film A after X-ray charging. a3) is the CsPbI_3 QD under 365 nm UV-light illumination. Panels b1)–b3) show the CsPbI_3 -QDs-less film B and panels c1)–c4) show the CsPbI_3 -QD-rich film C and its application to show the text of “ CsPbI_3 QDs”.

transitions in $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ from film A upon heating to about 343 K. The other X-ray imaging of a chicken bone is visible in the dark as demonstrated in Fig. S28.

We further explored X-ray imaging with film A by using large electric wires and connector plugs in size of $\sim 5 \times 5 \text{ cm}^2$ as imaging object in Fig. 14(c1)–14(c4). With the increase of X-ray power from 30 W to 60 W, a X-ray imaging photograph for the electric wires and connector plugs gradually appears to be visible in the dark as shown in Fig. 14(c2)–(c4). The X-ray imaging resolution for film A was testified in Fig. 14(d1). A X-ray imaging resolution of about 3.5 lp/mm emerges in film A in the dark in Fig. 14(d2). Fig. 14(d3) shows a X-ray imaging resolution test using $(\text{C}_8\text{H}_{20}\text{N})_2\text{MnBr}_4$ phosphor based screen. The ratio of signal to

background noise in film A in Fig. 14(d2) is higher than that in $(\text{C}_8\text{H}_{20}\text{N})_2\text{MnBr}_4$ phosphor based screen in Fig. 14(d3). The above results suggest that the developed $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ can be used for X-ray imaging.

4. Discussion

4.1. Electron de-trapping process from Bi^{2+} for determining VRBE at $\text{Bi}^{2+} {}^2P_{1/2}$

The VRBE diagram of NaYGeO_4 in Fig. 1(a) that was constructed in ref. [31] predicts that Bi^{3+} can act as a $0.85 \pm 0.5 \text{ eV}$ deep electron

Fig. 13. (a) Afterglow spectra after 254 nm charging, (b) RT iso-thermal decay curves, and (c) afterglow color coordinates for lanthanide and/or Bi³⁺ doped NaYGeO₄. (d1)–(d5) NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺, 0.002Pr³⁺ based silicone gel afterglow film D and its application to show text of “WHITE BiTbPr” in the dark. (d6) 40 h RT iso-thermal decay curve for NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺, 0.002Pr³⁺.

capturing centre, while Bi³⁺, Ce³⁺, Pr³⁺, and Tb³⁺ act as 1.48 eV, 3.80 eV, 2.0 eV, and 2.13 eV deep hole capturing centres. Fig. 1 still contains a large error of ± 0.5 eV for the prediction of Bi²⁺ electron trapping depth in NaYGeO₄ and NaLuGeO₄. The predicted VRBE in the Bi²⁺ ground state in NaYGeO₄ and NaLuGeO₄ in Fig. 1 is based on the statistical result that the average VRBE in the Bi²⁺ ground state in 15 inorganic compounds emerges in the range from about -3.5 to -4 eV [45]. There are three main methods to determine the vacuum referred binding energies in the ground and excited states of Bi²⁺. Based on the VB $\rightarrow$ Bi³⁺ charge transfer and the VRBE in the valence band (VB) of a compound, one may estimate the VRBEs in Bi²⁺ ground and excited states by further adding the energies of the characteristic Bi²⁺ transitions from $2p_{1/2}$ to $2p_{3/2}(1)$, $2p_{3/2}(2)$, and $2s_{1/2}$ [46]. Katayama *et al.* used this method in ref. [47] to determine the VRBE in the Bi²⁺ ground state location in MgGeO₃ where a value of -3.8 eV was obtained. The second method to estimate the VRBE in the Bi²⁺ $2p_{1/2}$ ground state is to determine the energy barrier for thermal quenching of Bi²⁺ $2p_{3/2} \rightarrow 2p_{1/2}$ emission in a compound [45,46,48]. Awater *et al.* used this method to determine the VRBE in Bi²⁺ $2p_{1/2}$ ground state in Li₂BaP₂O₇ to -3.84 eV

in ref. [46]. Unfortunately, photoluminescence of Bi²⁺ was not observed in the germanate compounds of this work and the Bi²⁺ level locations can not be derived by this method.

Fig. 1(a) predicts that the electron trap depth (0.85 ± 0.5 eV) of Bi³⁺ is about 1.33 ± 0.5 eV and $\sim 0.63 \pm 0.5$ eV less than the hole trap depths of Bi³⁺, Tb³⁺, and Pr³⁺. If this is correct, then electron liberation from Bi²⁺ and recombination with holes at Pr⁴⁺, Tb⁴⁺, and Bi⁴⁺ would give rise to a same TL glow peak but with characteristic emission from Pr³⁺, Tb³⁺, and Bi³⁺. One then can estimate the Bi²⁺ $2p_{1/2}$ ground state location by a thermoluminescence study, which is the third method to determine Bi²⁺ level location in an inorganic compound. The low-temperature TL emission (TLEM) spectra in Fig. 4 shows that a common TL glow peak near 270 K with Bi³⁺ emission in NaYGeO₄:0.004Bi³⁺ in Fig. 4(b), with Tb³⁺ emission in NaYGeO₄:0.004Bi³⁺, 0.005Tb³⁺ in Fig. 4(c), and with Pr³⁺ emission in NaYGeO₄:0.004Bi³⁺, 0.005Pr³⁺ in Fig. 4(d) was observed. This 270 K TL glow peak, named as Bi²⁺ TL peak, is absent in NaYGeO₄:0.005 Tb³⁺ in Fig. 4(a) when Bi³⁺ is absent. This indicates that there is an electron release process from Bi²⁺. Upon thermal stimulation at about 270 K, the captured electrons are released

Fig. 14. Proof-of-concept X-ray imaging by using (a1)-(a4) $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ based film and (b1)-(b4) $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ based film. (c1)-(c4) X-ray irradiation dose and (d1)-(d2) X-ray imaging resolution test for the $\text{NaYGeO}_4:0.003\text{Bi}^{3+}, 0.008\text{Tb}^{3+}$ based optical storage film A. The thickness of the wire connectors used in (c1) is ~ 2 cm. (d3) X-ray imaging using manganese halide $(\text{C}_8\text{H}_{20}\text{N})_2\text{MnBr}_4$ based scintillating film (reproduced with permission from Ref.[44], copyright 2021, Wiley).

from Bi^{2+} to recombine with holes trapped at Bi^{4+} , Tb^{4+} , or Pr^{4+} to produce typical $\text{Bi}^{3+} {}^3\text{P}_1 \rightarrow {}^1\text{S}_0$ and Tb^{3+} or $\text{Pr}^{3+} 4f \rightarrow 4f$ transitions. The electron trap depth of Bi^{3+} electron trapping centre in NaYGeO_4 has been calculated in Table 1 to about 0.64 eV. The VRBE in the $\text{Bi}^{2+} {}^2\text{P}_{1/2}$ ground state in NaYGeO_4 then can be deduced to ~ -3.29 eV by subtracting the trap depth from the conduction band bottom VRBE. The above obtained ~ -3.29 eV for $\text{Bi}^{2+} {}^2\text{P}_{1/2}$ ground state level location in NaYGeO_4 should be treated as indicative because the Bi^{2+} trap depth was determined based on a assumption that there is a first-order TL recombination kinetics and there is zero distribution in Bi^{2+} trapping

depth. Fig. S6(c)-S6(e) demonstrated that there is a distribution in Bi^{2+} trapping depth and the Bi^{2+} trap depth increases from ~ 0.45 eV to ~ 0.80 eV with increasing T_{clean} from 308 K to 353 K in Fig. S6(e). The VRBE in the $\text{Bi}^{2+} {}^2\text{P}_{1/2}$ ground state in NaYGeO_4 can also be deduced to between ~ -3.1 and ~ -3.45 eV in NaYGeO_4 . This value appears within the average range from ~ -3.5 eV to -4 eV for the VRBE in the Bi^{2+} ground state in inorganic compounds.

Fig. 4(b)-4(d) shows that the Bi^{3+} emission is absent in $\text{NaYGeO}_4:0.004\text{Bi}^{3+}, 0.005\text{Tb}^{3+}$ and $\text{NaYGeO}_4:0.004\text{Bi}^{3+}, 0.005\text{Pr}^{3+}$. Fig. 1 predicts that the hole trap depth of Bi^{3+} is less deep than that of

Tb³⁺ and Pr³⁺. It means that Tb³⁺ and Pr³⁺ are more stable hole capturing centres than Bi³⁺. During X-ray exposure, free holes prefer to be trapped by more stable Tb³⁺ and Pr³⁺ hole capturing centres, rather than by Bi³⁺ hole capturing centre. This leads to the absence of Bi³⁺ ³P₁→¹S₀ emission in NaYGeO₄:0.004Bi³⁺,0.005 Tb³⁺ and NaYGeO₄:0.004Bi³⁺,0.005Pr³⁺ as shown in Fig. 4(c) and 4(d). The same also applies for Fig. 13(a3) and Fig. 13(a4).

Fig. 1(b) predicts that Bi³⁺ can act as an about 0.75 ± 0.5 eV deep electron trap in NaLuGeO₄ and NaYGeO₄, and is about 1.38 ± 0.5 eV less deep than that of Tb³⁺ hole capturing centres. Fig. 1(b) further predicts that the VRBE at the conduction band bottom of NaLuGeO₄ is about 0.1 eV lower than that of NaYGeO₄. If the above predictions are correct, the Bi³⁺ electron trapping depth will increase when Lu³⁺ is substituted by Y³⁺ in NaLu_{1-x}Y_xGeO₄. The change of the Bi³⁺ electron trapping depth is verified by the thermoluminescence study of NaLu_{1-x}Y_xGeO₄:0.01Bi³⁺ in Fig. 5(a) and NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺,0.008Tb³⁺ in Fig. 5(b) where Bi³⁺ acts as the electron trapping centre, while the Bi³⁺ in Fig. 5(a) and the Tb³⁺ in Fig. 5(b) acts as the hole trapping and recombination centres. Fig. 5(a)-5(b) shows that, with the increase of x in NaLu_{1-x}Y_xGeO₄:0.01Bi³⁺ and NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺,0.008Tb³⁺, the Bi²⁺ TL glow peak gradually shifts about 68–50 K towards higher temperature, corresponding about 0.13 eV increase of electron trap depth as listed in column 4 of Table 1. The shifting of the Bi²⁺ TL glow peak is due to the increased activation energy of electron liberation from Bi²⁺ because of conduction band rising with increasing x in NaLu_{1-x}Y_xGeO₄. For x = 0 in Fig. 5(b), the electron trap depth of Bi³⁺ electron trapping centre in NaLuGeO₄ has been determined to be ~ 0.50 eV in Table 1. The VRBE in the Bi²⁺ ²P_{1/2} ground state in NaLuGeO₄ then can be deduced to ~ -3.22 eV by subtracting the trap depth from the conduction band bottom VRBE. This value is close to that of ~ -3.29 eV for Bi²⁺ ²P_{1/2} in NaYGeO₄ and appears within the average range from ~ -3.5 eV to -4 eV for the VRBE in the Bi²⁺ ground state in inorganic compounds.

4.2. Designing afterglow phosphors based on electron liberation from Bi²⁺ for anti-counterfeiting application

For a same sample of x = 1, a TL glow peak near 283 K was observed in Fig. 5(b) and a TL glow peak near 311 K was observed in Fig. 5(c). For x = 1 in Fig. 5(c), there is 30 s delay time at 303 K between 254 nm UV-light and TL-readout. Fig. S6(c)-S6(e) have already demonstrated that there is a distribution in Bi²⁺ trapping depths in x = 1 sample. A part of stored charge carriers therefore has been faded at 303 K prior to the start of TL-readout and then a higher TL glow peak appears for x = 1 in Fig. 5(c). The 311 K TL glow peak for x = 1 is still attributed to the electron liberation from Bi²⁺ and recombination with holes captured at Tb⁴⁺. The same applies for the TL glow peaks near 303 K for x = 0–0.75 in Fig. 5(c). Fig. 5(d)-5(e) show that Tb³⁺ afterglow phosphor can be designed by using electron release from Bi²⁺ and changing x in NaLu_{1-x}Y_xGeO₄:0.003Bi³⁺,0.008Tb³⁺ resulting in conduction band engineering.

Fig. 7(c) shows that the integrated TL intensity of NaYGeO₄:0.003Bi³⁺,0.008Tb³⁺ after exposure to 254 nm UV-light is about 1.3 times higher than that of NaYGeO₄:0.004Bi³⁺. After X-ray charging in Fig. 7(b), the integrated TL intensity of NaYGeO₄:0.004Bi³⁺ is about 4 times higher than that of NaYGeO₄:0.003Bi³⁺,0.008 Tb³⁺. One should realize that charge carrier formation process induced by X-rays and UV-light charging is different. For X-ray charging, mobile free electrons and holes are created [31,49,50]. For UV-light charging, mobile electrons and holes are formed by a photo-induced ionization process from the excited states of a luminescence centre in compound like in Eu²⁺,Tm³⁺-codoped Ca₃Si₂O₇ in ref.[51]. Fig. 9(b)-9(d) shows the TL excitation (TLE) plots for NaYGeO₄:0.005 Tb³⁺ and NaYGeO₄:0.004Bi³⁺,0.005 Tb³⁺. The two phosphors can be charged via the Tb³⁺ 4f → 5d and Tb³⁺ → CB IVCT transitions or Bi³⁺ D-band. Fig. S6(b) compares the TL glow curves for NaYGeO₄:0.003Bi³⁺,0.008Tb³⁺ charged by X-rays and 254 nm UV-light. The TL peak appears at ~ 30 K

higher by X-ray charging than that by 254 nm UV-light charging. One possible reason is that free charge carriers created by X-rays are prefer captured by stable and deeper Bi²⁺ trapping depth since there is a distribution in Bi²⁺ trapping depth as evidenced in Fig. S6(c)-S6(e). Another possible reason is that the T_{max} is smaller when the hole and electron trap centers are close by and center-to-center recombination is expected. With photon excitation those centers are being filled preferentially. The Bi³⁺ electron trap filled with photon excitation or with X-rays can therefore be equally deep below the CB-bottom. However with center-to-center recombination the electron needs not be thermally excited to the CB. The similar applies to Bi³⁺ co-doped NaYGeO₄ in Fig. 7(b) and 7(c), NaYGeO₄:yBi³⁺,0.008 Tb³⁺ (y = 0.001–0.012) in Fig. S13(b) and S13(c), and NaYGeO₄:0.003Bi³⁺,0.008Tb³⁺,0.002Pr³⁺ in Fig. S27.

Because of the intense afterglow from NaYGeO₄:0.004Bi³⁺ and NaYGeO₄:0.003Bi³⁺,0.008Tb³⁺ as demonstrated in Fig. 3(h)-3(i), 8, and Fig. S19-S20, this direct afterglow can be used as illumination light source to display text and QR code in the dark as shown in Fig. 11 and S23. Color-tailorable afterglow has been explored for anti-counterfeiting application. Fig. S24 shows the PLE, PL or absorption spectra for NaYGeO₄:0.01Tb³⁺ and CsPbI₃ quantum dots (QDs). There is an overlap between the absorption spectrum of CsPbI₃ QDs and the PL spectrum of NaYGeO₄:0.01Tb³⁺ in 300–650 nm, indicating the possible energy transfer from NaYGeO₄:0.01Tb³⁺ to CsPbI₃ QDs via a reabsorption process. However, the particle size of NaYGeO₄:0.004Bi³⁺,0.005Tb³⁺ and NaYGeO₄:0.003Bi³⁺,0.008 Tb³⁺ in Fig. S1 is much larger than that of CsPbI₃ QDs. The re-absorption of the afterglow from NaYGeO₄:0.003Bi³⁺, 0.008 Tb³⁺ by CsPbI₃ QDs may not efficient and this leads to the difficulty to largely tailor the afterglow color in Fig. 12.

Color-tailorable afterglow was further explored by designing electron traps, hole traps, and recombination centres in NaYGeO₄. Fig. 1(a) shows that the VRBE in the Nd²⁺ ground state is inside the conduction band. It means that Nd³⁺ can not act as an electron capturing centre but can act as a luminescence centre with Nd³⁺ 4f → 4f emission in the infrared range via energy transfer from Bi³⁺ to Nd³⁺ in NaYGeO₄[52]. This prediction is evidenced by the Bi³⁺ and Nd³⁺ infrared afterglow in Fig. 3(d) and the TLEM spectrum of NaYGeO₄:0.004Bi³⁺,0.005Nd³⁺ in Fig. 6(c). Fig. 1(a) predicts that Pr³⁺ can act as a hole capturing and recombination centre in NaYGeO₄. White afterglow appears in Bi³⁺, Tb³⁺,Pr³⁺-codoped NaYGeO₄ as demonstrated in Fig. 13 and Fig. S26-27 where Bi³⁺ acts as an electron trap, while Bi³⁺, Tb³⁺, and Pr³⁺ act as hole trapping and recombination centres.

4.3. X-ray imaging application exploration

X-ray imaging was testified by using the prepared films with different objects in Fig. 14 and S28-S29 and a resolution of 3.5 lp/mm for X-ray imaging was obtained in Fig. 14(d2). To further increase the resolution for the X-ray imaging, the particle size of the storage phosphors needs to be decreased further by ball milling or synthesizing nano-sized phosphor. The optimized NaYGeO₄:0.003Bi³⁺,0.008 Tb³⁺ has been further evaluated for X-ray imaging application. Fig. 10(a) shows that the integrated TL intensity for NaYGeO₄:0.003Bi³⁺, 0.008Tb³⁺ increases linearly with increasing X-rays exposure time, indicating the possible application as X-rays dosimeter. Fig. 10(b) shows that NaYGeO₄:0.003Bi³⁺,0.008 Tb³⁺ has good chemical stability after exposure to water, which is important for practical application. Fig. 10(c)-10(d) and S15-S18 shows that the stored charge carriers in NaYGeO₄:0.004Bi³⁺,0.008 Tb³⁺ and NaYGeO₄:0.004Bi³⁺ can be excited by different light source to generate optically stimulated Tb³⁺ and Bi³⁺ luminescence. One then may design X-ray imaging application using this feature[49].

5. Conclusions

Photoluminescence spectroscopy, vacuum referred binding energy

diagram (VRBE), and thermoluminescence technique have been combined to investigate the capturing and transport processes of electrons and holes in $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4$ in order to develop storage phosphors for X-ray imaging and anti-counterfeiting applications. In $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.004\text{Bi}^{3+},0.005\text{Ln}^{3+}$ ($\text{Ln} = \text{Tb}$ or Pr), the Bi^{3+} ion acts as an electron capturing centre, while Bi^{3+} and Ln^{3+} act as the hole capturing and recombination centres. The trapped electrons are liberated from Bi^{2+} to recombine with holes captured at Bi^{4+} or Ln^{4+} to generate characteristic $\text{Bi}^{3+} {}^3\text{P}_1 \rightarrow {}^1\text{S}_0$ emission and Tb^{3+} or $\text{Pr}^{3+} 4f \rightarrow 4f$ transitions. The trap depth of Bi^{3+} electron capturing centre has been determined to about 0.64 eV by thermoluminescence study. The VRBE in the $\text{Bi}^{2+} {}^2\text{P}_{1/2}$ ground state is then derived to -3.29 eV in NaYGeO_4 . The electron trap depth produced by Bi^{3+} codopant in $\text{NaLu}_{1-x}\text{Y}_x\text{GeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ solid solutions can be adjusted, by increasing x , resulting in conduction band engineering. Good afterglow phosphors were developed by using electron liberation from Bi^{2+} in Bi^{3+} and/or Tb^{3+} doped NaYGeO_4 . The integrated TL intensity of the optimized $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ after exposure to X-rays is about 4.5 and 1.1 times higher than that of the state-of-the-art $\text{BaFBr}(\text{D})\text{:Eu}^{2+}$ storage phosphor. Intense initial $\text{Tb}^{3+} 4f \rightarrow 4f$ afterglow appears in $\text{NaYGeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ and more than 40 h afterglow can be measurable in $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ after X-ray charging. We have shown proof-of-concept color tailoring for anti-counterfeiting applications by combining perovskite CsPbI_3 quantum dots (QD) with finely designed charge carriers in NaYGeO_4 where Bi^{3+} acts as an electron trap while both Tb^{3+} and Pr^{3+} act as the hole trapping and recombination centres. Proof-of-concept X-ray storage application was demonstrated in the optimized $\text{NaYGeO}_4:0.004\text{Bi}^{3+}$ and $\text{NaYGeO}_4:0.003\text{Bi}^{3+},0.008\text{Tb}^{3+}$ phosphors which were dispersed in the silicon gel based flexible X-ray imaging films. This work not only provides with experimental evidence on the VRBE in $\text{Bi}^{2+} {}^2\text{P}_{1/2}$ ground state in NaYGeO_4 and NaLuGeO_4 , but also shows that how to design and develop good afterglow phosphors for anti-counterfeiting and X-ray imaging by deeply studying and controlling the trapping and de-trapping processes of charge carriers in bismuth and/or lanthanides doped inorganic compounds. Therefore, this work can accelerate the development of afterglow phosphors in a rational way instead of by the typical trial-and-error method.

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Acknowledgements

This work is financially supported by the National Natural Science Foundation of China (No. 12104170) and partly by Scientific Research Funds of Huaqiao University (No. 21BS106). We thank the support from Instrumental Analysis Center of Huaqiao University. We acknowledge Ou et al. in ref. [1] and Jian Xu for providing samples of $\text{NaLuF}_4\text{:Tb}(15 \text{ mol}\%)\text{@NaYF}_4$ and transparent $(\text{Y}, \text{Ga})_3\text{Al}_2\text{Ga}_3\text{O}_{12}$ garnet afterglow ceramics for comparison studies in this work.
