Abstract

The Riemann problem for the unsteady, one dimensional Euler equations together with the constant-covolume equation of state is solved exactly. The solution is then applied to the Random Choice Method to solve the general initial-boundary value problem for the Euler equations. The iterative procedure to find p^* , the pressure between the acoustic waves, involves a single algebraic (non-linear) equation, all other quantities follow directly throughout the x - t plane, except within rarefaction fans, where an extra iterative procedure is required.

1. Introduction

The ideal-gas kinetic theory assumes that molecules occupy a negligible volume and that they do not exert forces on one another. In applications such as in combustion processes, these assumptions are no longer accurate descriptions of the problem. In this paper we incorporate covolume, that is to say, we assume that molecules occupy a finite volume b, so that the volume available for molecular motion is v - b. The resulting thermal equation of state is

$$p(v - b) = RT \tag{1}$$

Here p, v, R and T are pressure, volume, the gas constant and absolute temperature respectively, with $v = 1/\rho$; ρ is density.

If one were to assume intermolecular forces as well, then the Van der Waals' equation of state would result. However, we are only interested in eq. (1) where b is constant (with dimensions m^3/kg). Corner [1] reports on experimental results for a good range of solid propellants, where he observed that the covolume b varied very little, i.e. $0.9 \times 10^{-3} \, m^3/kg \leqslant b \leqslant 1.1 \times 10^{-3} \, m^3/kg$. The best values of b lead to errors no greater than 2% and thus we feel there is some justification in using eq. (1) with b = constant, when modelling gas dynamical events associated with solid propellant burning.

The main motivation of the present work is to extend the applicability of the Random Choice Method (RCM) to model gas dynamical events arising from, and coupled with, combustion phenomena. Since RCM uses the exact solution of the Riemann problem, our first task will be to devise an efficient Riemann solver. In Ref. [2] we derived a number of covolume relations and indicated a solution strategy based on the Newton-Raphson Nethod applied to a 3 x 3 system of algebraic equations. For rarefaction fans we also suggested a similar approach to solve another 3 x 3 system. The resulting Riemann solver was found to be more efficient than that based on the Godunov iteration when applied to the special case b = 0 (ideal gas), but the net gains were limited.

The present Riemann solver is much more efficient; it is an extension of that proposed in Ref.[3] for ideal gases. The two iteration procedures that are present (one the pressure p* between the acoustic waves and the other for the density ρ inside rarefaction fans) involve a single algebraic equation. The Newton-Raphson Method works well in both cases.

The implementation of RCM using the exact Riemann solver is carried out on a non-staggered grid, whereby the solution to the next time level is advanced in a single step. This programming strategy has a number of advantages over the more common staggered grid approach. Simplicity is one of them. Use of irregular/adaptive grids is another. The original idea appears to be due to Colella [4].

The remaining part of this paper is organised as follows: Section 2 defines the Riemann problem and delineates the solution strategy. In section 3 we collect the covolume relations required to solve the problem. In section 4 we solve the Riemann problem. In section 5 we describe the implementation of RCM. In section 6 we solve a shock-tube problem exactly by direct application of the present Riemann solver and approxiately via the Random Choice Method. Results are compared and discussed. Finally, in section 7 we draw some conclusions and indicate areas of applications of present results.

2. The Riemann Problem

We consider the Riemann problem for the unsteady one-dimensional Euler equations together with the covolume equation of state (1) with constant b, namely

$$U_{\dagger} + F(U)_{\chi} = 0 \tag{2}$$

$$U(x,t_0) = \begin{cases} U_1, & x \leq x_0 \\ U_r, & x \geq x_0 \end{cases}$$
 (3)

where $-\infty < x < \infty$, $t > t_0$. Here U = U(x,t) with x and t denoting space and time respectively. In eq. (2) subindices denote partial differentiation, as usual. U and F(U) are vectors of conserved variables and fluxes respectively. These are given by

$$U = \begin{bmatrix} \rho \\ \rho u \\ E \end{bmatrix}, \quad F(U) = \begin{bmatrix} \rho u \\ \rho u^2 + p \\ (E + p)u \end{bmatrix}$$
 (4)

where u is velocity, e is specific internal energy and E is total energy given by

The initial condition (3) consists of two constant states U_1 and U_r .

Note that equation (1) serves as a closure condition for system (2), which has three differential equations and four unknowns. A corresponding caloric equation of state gives an expression for the specific internal energy in eq. (5) in terms of the unknowns of system (2).

The solution of the Riemann problem (1) - (5) for $t > t_0$ can be represented in the half x - t plane as in Fig. 1.

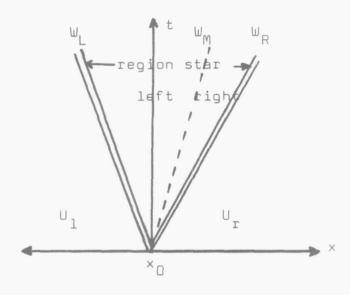

Fig. 1: Solution of Riemann problem with data U_1 and U_r

There are three waves present: W_L , W_M and W_R . The middle wave W_M is always a contact discontinuity, the left wave W_L is either a shock or a rarefaction and the right wave W_R is either a shock or a rarefaction. Hence, there are four possible wave patterns. The region star between waves W_L and W_R is characterised by having pressure $p^* = \text{constant}$ and velocity $u^* = \text{constant}$ with $\rho = \rho_1^*$ between W_L and W_M (star left) and $\rho = \rho_T^*$ between W_M and W_R (star right). In the portion of the half x-t plane to the left of wave W_L the solution is equal to the constant state W_L (data). Similarly W_L in the region to the right of wave W_R . The solution W_L at a time W_L inside a rarefaction fan (W_L or W_R) varies smoothly with W_L .

The principal step of the solution procedure is the determination of the solution in the region star. We call this the star step. A feature of the present Riemann solver is that the star-step consists of a single (non-linear) algebraic equation for the pressure p*. Other quantities in the region star follow directly. Clearly, the solution for p* must be found iteratively, since the type of waves \mathbf{W}_{L} and \mathbf{W}_{R} is not known a-priori. This must be determined as part of the solution.

The star-step requires equations connecting U_1 (data) to U_1^* and U_r (data) to U_r^* . In each situation one must derive equations for the case in which the connecting wave is a shock or a rarefaction. These equations are manipulated in such a way that the velocities u_1^* and u_r^* are expressed as

$$u_1^* = f_1(p^*, U_1)$$

 $u_r^* = f_r(p^*, U_r)$
(6)

But $u_1^* = u_r^*$ gives a single algebraic non-linear equation for the unknown p^* , i.e.

$$f(p^*, U_1, U_r) \equiv f_1(p^*, U_1) + f_r(p^*, U_r) = 0$$
 (7)

A certain amount of work is involved in determining the form of the functions f_1 and f_r in equations (6), and thus f in eq. (7).

Once p* is known from eq. (7) all other quantities in region star follow directly from explicit relations. If both waves W_L and W_R are shocks then the solution of the Riemann problem has been determined everywhere in the half x - t plane. However if a rarefaction fan is present the solution inside it requires another iterative procedure. This is unlike the ideal-gas case, where the solution inside rarefaction fans follows directly from the star step (also iterative). We present an economical way of finding the solution inside rarefaction fans. Instead of solving a 3 x 3 non-linear system (as suggested in Ref. [2]) we solve a single non-linear equation for the density ρ . Other quantities follow directly.

Next, we collect some basic relations for shock and rarefaction waves and derive covolume expressions for the internal energy and the sound speed. These will be later utilised in the star step.

3. Covolume relations

Here we collect some of the covolume equations derived in Ref. 2. There, we showed that the specific internal energy e is given by

$$e = \frac{p(1 - b\rho)}{\rho(\gamma - 1)} \tag{8}$$

and the sound speed c is given by

$$c = \left[\frac{p_{\gamma}}{\rho (1 - b_{\rho})}\right]^{\frac{1}{2}} \tag{9}$$

Here γ denotes ratio of specific heats, as usual. The derivation of equations across shocks and rarefactions is now dealt with separately.

3.1 Shock relations

Consider the case of a right travelling shock wave of speed S_r . In the steady frame of reference attached to the shock the usual equations for mass momentum and energy apply. In Ref. [2] we formulated the solution of the star step in terms of the pressure p* and two parameters M_l and M_r . In the present paper the solution strategy is different, but expressions for M_r and M_l are still useful. For a right moving wave (shock or rarefaction) M_r is defined as

$$M_{r} = \frac{p^{\star} - p_{r}}{u^{\star} - u_{r}} \tag{10}$$

For a right travelling shock, the steady shock relations give

$$M_{r}^{2} = \frac{\rho_{r}(p^{*} - p_{r})D_{R}}{D_{R} - 1}$$
 (11)

where $D_R = \rho_r^*/\rho_r$ is the density ratio across the shock wave. Also, the standard Hugoniot relation can be written as

$$e^* - e_r = \frac{1}{2} \left(\frac{p_r}{p_r} \right) \left[\frac{(P_R + 1)(D_R - 1)}{D_R} \right]$$
 (12)

where $P_R = p^*/p_r$ is the pressure ratio across the shock. Substitution of e from eq. (8) into eq. (12) gives a relationship between P_R and D_R across the shock i.e.

$$D_{R} = \frac{(\gamma + 1)P_{R} + (\gamma - 1)}{(\gamma - 1 + 2b\rho_{r})P_{R} + (\gamma + 1) - 2b\rho_{r}}$$
(13)

which, if used in eq. (11), leads to

$$M_{r} = \left\{ \left[\frac{(\gamma + 1)}{2} \frac{\rho_{r} p_{r}}{(1 - b\rho_{r})} \right] \left[P_{R} + \frac{(\gamma - 1)}{(\gamma + 1)} \right] \right\}^{\frac{1}{2}}$$
(14)

Similarly, for the left travelling wave W_L a parameter M_1 can be defined as follows

$$M_{1} = -\frac{(p^{*} - p_{1})}{(u^{*} - u_{1})} \tag{15}$$

which, after using appropriate relations, becomes

$$M_{1} = \left\{ \frac{\left(\gamma + 1\right) \rho_{1} p_{1}}{2 \left(1 - b\rho_{1}\right)} \right] \left[P_{L} + \frac{(\nu - 1)}{(\gamma + 1)}\right]^{\frac{1}{2}}$$
(16)

Here $P_L = p*/p_1$ is the pressure ratio across the left moving shock.

3.2 Rarefaction relations

In order to obtain expressions for $\rm M_{1}$ and $\rm M_{r}$ in the case in which waves $\rm W_{L}$ and $\rm W_{R}$ are rarefaction waves we need the generalised Riemann invariants and the isentropic relations. For a left rarefaction

$$J_L = u + \frac{2c}{(\gamma - 1)} (1 - b\rho) = constant$$
 (17)

and

$$\frac{\rho_1^*}{(1-b\rho_1^*)} = \frac{\rho_1}{(1-b\rho_1)} P_L^{1/\gamma}$$
 (18)

For a right rarefaction we have

$$J_{R} = u - \frac{2c}{(\gamma - 1)} (1 - b_{\rho}) = constant$$
 (19)

and

$$\frac{\rho_r^*}{(1-b\rho_r^*)} = \frac{P_r}{(1-b\rho_r)} P_R^{1/\gamma}$$
(20)

Use of eqs. (17) - (18) gives for M_1

$$M_{1} = \frac{(\gamma - 1)}{2} \left[\frac{\rho_{1} p_{1}}{\gamma (1 - b\rho_{1})} \right]^{\frac{1}{2}} \left[\frac{1 - P_{L}}{1 - P_{L} 2\gamma} \right]$$
 (21)

and use of eqs. (19) - (20) gives for M_r

$$M_{r} = \frac{(\gamma - 1)}{2} \left[\frac{\rho_{r} p_{r}}{\gamma (1 - b\rho_{r})} \right]^{\frac{1}{2}} \left[\frac{1 - P_{R}}{1 - P_{R} \frac{\gamma - 1}{2\gamma}} \right]$$
 (22)

We now return to eq. (6). Note that for a left wave, from definition (15) for M_{1} we have

$$u^* = u_1 + \frac{(p_1 - p^*)}{M_1}$$

or

$$u^* = u_1 + f_1(p^*, U_1)$$
 (23)

where

$$f_{1} = \begin{cases} (1 - P_{L}) \left[\frac{2(1 - b\rho_{1})p_{1}}{(\gamma + 1)\rho_{1}} \right]^{\frac{1}{2}} & \text{if } P_{L} \geqslant 1 \\ \frac{2(1 - b\rho_{1})C_{1}}{(\gamma - 1)} \left[1 - P_{L} \right]^{\frac{\gamma - 1}{2\gamma}} & \text{if } P_{L} < 1 \\ (rarefaction) \end{cases}$$
 (24a)

Similarly, for a right wave definition (10) gives

$$u^* = u_r - f_r(p^*, U_r)$$
 (25)

where

$$f_{r} = \begin{cases} (1 - P_{R}) \left[\frac{2(1 - b\rho_{r})p_{r}}{(\gamma + 1)\rho_{r}} \right]^{\frac{1}{2}} & \text{if } P_{R} \geqslant 1 \\ \frac{2(1 - b\rho_{r})C_{r}}{(\gamma - 1)} \left[1 - P_{R} \right] & \text{if } P_{R} \leqslant 1 \\ & \text{(26a)} \end{cases}$$

$$(26a)$$

$$(26b)$$

$$(26b)$$

We have now completely determined the problem for the $\underline{\text{star-step}}$. From eqs. (23) and (25) the single equation (7) for p* results, where f_1 and f_r are given by eqs. (24) and (26) respectively.

4. Algorithm for the solution of the Riemann problem

Here we use all relations developed in section 3 to implement an efficient algorithm for completely solving the Riemann problem with constant covolume in the half plane x - t.

As pointed out in section 2 the solution procedure consists basically of the star-step and the rarefaction fan step. The principal part of the star step is the solution of an equation for the pressure p^* in region star. The rarefaction fan step consists of finding the complete solution inside a rarefaction fan; its principal step is the solution of a single equation for the density ρ , Both steps contain an iteration. We shall deal with each of them separately.

4.1 The star step

The main part here is the determination of p^* by solving the single non-linear algebraic equation

$$f(p^*, U_1, U_r) \equiv f_1(p^*, U_1) + f_r(p^*, U_r) + u_1 - u_r = 0$$
 (27)

where f_1 and f_r are given by eqs. (24) and (26). We do this by a Newton-Raphson iteration procedure of the form

$$p_{(k)}^{*} = p_{(k-1)}^{*} + \delta_{(k-1)}$$
 (28)

where

$$\delta_{(k)} = -f(p_{(k)}^*, U_1, U_r)/f_{(k)}^*$$

Here k denotes the iteration and $\delta_{(k)}$ is an increment at the k-th iteration.

The method requires evaluation of derivatives

$$f'(k) = \frac{d}{dp^*} f(p^*, U_1, U_r) |_{p^* = p^*(k)}$$

at the known point $p^* = p^*_{(k)}$ and an initial (guess) value p^*_0 . An economical guess value would be $p^*_0 = \frac{1}{2}(p_1 + p_r)$, but it could be inaccurate which can increase the number of iterations for convergence. We say that iteration procedure has converged to the solution at iteration k = K if

$$CHA = \frac{|p_{K}^{*} - p_{(K-1)}^{*}|}{p_{(K)}^{*}} \leq TOL$$
 (29)

where TOL is a chosen tolerance, e.g. $TOL = 10^{-4}$ is found to give sufficiently accurate solutions.

An accurate (although expensive) guess value p_0^* can be found if we assume that both acoustic waves W_L and W_R are rarefaction waves, that is in evaluating f_1 and f_r in eq. (27) for p^* , eqs. (24b) and (26b) apply. Algebraic manipulations give a closed form solution for p_0^* as

$$p_{0}^{*} = \left\{ \frac{(1 - b\rho_{1})C_{1} + (1 - b\rho_{r})C_{r} + \frac{(\gamma - 1)}{2}(u_{1} - u_{r})}{\frac{(\gamma - 1)}{(1 - b\rho_{1})C_{1}/p_{1}^{2\gamma}} + (1 - b\rho_{r})C_{r}/p_{r}^{2\gamma}} \right\} \frac{2\gamma}{(\gamma - 1)}$$
(30)

Clearly if both W_L and W_R are rarefaction waves, then eq. (30) gives the exact solution for p*. But even if the assumption leading to eq. (30) is not true the estimate p_0^* is quite accurate [3] even for cases involving shocks of strength of about 3. The reason for this is that the rarefaction and shock branches of the p - u curve (see Ref. [5]) have 1st and 2nd continuous derivatives at their intersection point. Thus a continuation of, say, a shock branch via the rarefaction branch is a good approximation for data states U_1 and U_r that are sufficiently close, in a given sense.

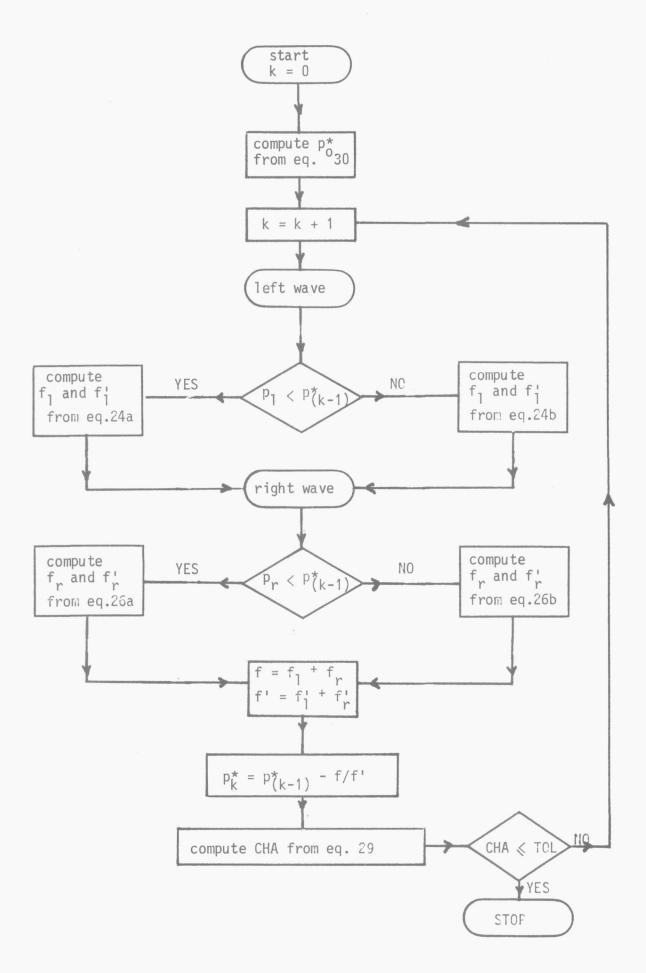

Figure 2: Algorithm for finding p*

If the solution of the Riemann problem is used in a local sense, as applied to the Random Choice Method, then there may well be one or two genuine discontinuities (shocks or contacts) in the flow field at a given time. Thus typically 98% of the local Riemann problems have data with close states and thus p_0^* as given by eq. (30) is very accurate. A single iteration is performed in most, if not all, of these cases.

Fig. 2 illustrates the algorithm for solving eq. (27) for p*. Once p* has been found u* follows directly from any of eqs. (23) or (25). In practice, it is advisable to take a mean value. The determination of ρ_1^* and ρ_r^* (Fig. 1) depends now on the type of waves W_L and W_R. For instance if W_R is a shock wave then ρ_r^* follows directly from eq. (13). If W_L is a shock wave we use the counterpart of eq. (13) to find ρ_1^* . If W_L is a rarefaction then eq. (18) gives ρ_1^* ; if W_R is a rarefaction eq. (20) gives ρ_r^* . Thus, the complete solution of the Riemann problem in the region star has been obtained.

A simple but important Riemann problem is that arising at boundaries. The solution has closed form and is given in the next section.

4.2 The Riemann problem at a moving boundary

Consider the right boundary and assume this is given by a piston moving with known speed $V_{\rm p}$. If reflections are to be allowed then the following boundary conditions apply

$$\rho_{r} = \rho_{1}$$
, $u_{r} = -u_{1} + 2V_{p}$, $p_{r} = p_{1}$ (31)

Here subscript I denotes last grid point inside the computational domain, and subscript r denotes fictitious grid point immediately to the right of the piston.

The Riemann problem with data (31) has solution as depicted in Fig.1 with $u^* = V_p$ and W_L and W_R both of the same type, i.e. they are both rarefactions or both shocks.

Now we find the pressure p* explicitly. It is easy to see that the functions f_1 and f_r in eq. (27) are identical and that $f_1 + u_1 - V_p = 0$.

If $\rm V_p > u_1$ then both $\rm W_L$ and $\rm W_R$ are rarefaction waves and the solution for $\rm p^*$ is

$$p^* = p_1 \left[1 - \frac{(\gamma - 1)(V_p - u_1)}{2(1 - b\rho_1)C_1} \right]^{\frac{2\gamma}{\gamma - 1}}$$
(32)

If $V_{\rm p}\leqslant u_{\rm l}$ then both $W_{\rm L}$ and $W_{\rm R}$ are shock waves with

$$p^* = p_1 \left[\frac{2\alpha_1 + (u_1 - V_p)^2 + (u_1 - V_p)\sqrt{4\alpha_1(1 - \beta) + (u_1 - V_p)^2}}{2\alpha_1} \right]$$
(33)

with

$$\alpha_{1} = \frac{2(1 - b\rho_{1})p_{1}}{(\gamma + 1)\rho_{1}} \quad , \quad \beta = \frac{\gamma - 1}{\gamma + 1}$$

$$(34)$$

For the left boundary the analysis is identical and the result is

$$p^* = p_r \left[1 - \frac{(\gamma - 1)(u_r - V_p)}{2(1 - b\rho_r)C_r} \right]^{\frac{2\gamma}{\gamma - 1}}$$
(35)

if $V_p < u_r$ (2 rarefactions)

and
$$p^* = p_r \left[\frac{2\alpha_r + V_p - u_r)^2 + (V_p - u_r)\sqrt{4\alpha_r(1 - \beta) + (V_p - u_r)^2}}{2\alpha_r} \right]$$
(36)

if $\rm V_p>u_r$ (2 shocks), where α_r is given in eq. (34) with $\rho_1,\; p_1$ replaced by $\rho_r,\; p_r.$

The problem that remains is the determination of the solution inside rarefaction fans.

4.3 Solution inside rarefaction fans

We only consider one case in detail. Suppose the left travelling wave W_L is a rarefaction wave as illustrated in Fig.3. Consider a general point Q (\hat{x}, \hat{t}) inside the rarefaction fan bounded by characteristics $\frac{dx}{dt} = u_1 - c_1$ (head) and $\frac{dx}{dt} = u^* - c_1^*$ (tail). A characteristic ray through the origin and Q has slope $\frac{dx}{d\hat{t}} = u - c$ in the x - t plane, where both u and c are unknowns of the problem. Then

$$u = \frac{\hat{X}}{\hat{T}} + c \tag{37}$$

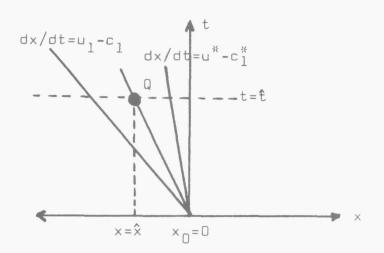

Figure 3: Point $Q(\hat{x}, \hat{t})$ inside rarefaction fan centered at (0,0).

Use of the left Riemann invariant J_L given by eq. (17) and of eq. (37) gives

$$c[1 + \frac{2}{(Y - 1)} (1 - b_{\rho})] = J_{L}(U_{1}) - \frac{\hat{x}}{\hat{t}}$$
 (38)

Now using definition (9) of sound speed and isentropic relation (18), with ρ_1^* replaced by ρ , at point Q we obtain

$$p = p_1 \left(\frac{1 - b\rho_1}{\rho_1} \right)^{\gamma} \quad \left(\frac{\rho}{1 - b\rho} \right)^{\gamma}$$
 (39)

Further algebraic manipulations give

$$F_{L} = \rho^{(\gamma-1)}(\gamma + 1 - 2b\rho)^{2} - \beta_{1}(1 - b\rho)^{\gamma+1} = 0$$
 (40)

and

$$\frac{\partial F_{L}}{\partial \rho} = (\gamma + 1) [b\beta_{1} (1 - b\rho)^{\gamma} + (\gamma + 1 - 2b\rho)(\gamma - 1 - 2b\rho)\rho^{\gamma - 2}]$$
 (41)

where the constant $\boldsymbol{\beta}_1$ is given by

$$\beta_{1} = \frac{\left\{ (\gamma - 1) \left[J_{L} (U_{1}) - \frac{\hat{x}}{\hat{t}} \right] \right\}^{2}}{\gamma p_{1} (\frac{1 - b p_{1}}{p_{1}})}$$
(42)

Eq. (40) is a non-linear algebraic equation for ρ . We solve this using a combination of the Newton-Raphson and the Secant Methods. Once ρ is found, to a given accuracy, the pressure p follows immediately from eq. (39). The sound speed c is now known from eq. (9) and velocity u follows directly from eq. (37).

For the case of a right rarefaction the analysis is entirely analogous. The equation for ρ inside the fan is

$$F_{R} = \rho^{(\gamma-1)} (\gamma + 1 - 2b\rho)^{2} - \beta_{r} (1 - b\rho)^{\gamma+1} = 0$$
 (43)

where

$$\beta_{r} = \frac{\left[\hat{x}/\hat{t} - u_{r} + \frac{2c_{r}}{(\gamma - 1)}(1 - b\rho_{r})\right]^{2}}{\gamma p_{r}(\frac{1 - b\rho_{r}}{\rho_{r}})^{\gamma}}$$
(44)

Then p follows from an equation like eq. (39) with ρ_1 , p_1 replaced by ρ_r , p_r . The sound speed c follows from the definition (9) and u is given by

$$u = \hat{x}/\hat{t} - c \tag{45}$$

The exact solution of the Riemann problem with constant covolume is now known everywhere in the half x - t plane (Fig. 1).

5. The Random Choice Method (RCM) with covolume

In this section we describe the way the exact solution of the Riemann problem can be used locally to obtain (numerically) the global solution of the general initial-boundary value problem for the Euler equations.

Consider the system of equations (2) in a finite domain $0 \leqslant x \leqslant L$ subject to a general initial data at a time t_n , say. If the spatial domain is

discretised into M cells of size Δx and the general data is approximated by piece-wise constant functions then the original problem has been replaced by a sequence of local Riemann problems Rp(i, i+1) for i = 1, ... M - 1. In addition, there are two more boundary Riemann problems RP(0,1) and RP(M, M+1). Data for RP(i, i+1) consists of two constant states U_i^n (left) and U_{i+1}^{n} (right). The discrete problem is illustrated in Fig. 4. Each local Riemann problem has solution as depicted in Fig. 1 and can be solved exactly by the method of section 4. Now the solution is valid locally for a restricted range of space and time, i.e. before wave interaction occurs. For a sufficiently small time increment ΔT the local solutions are unique in their respective domains so that the global solution at time $t_{n+1} = t_n + \Delta T$ is uniquely defined for $0 \leqslant x \leqslant L$. Within cell i (Fig.4), the solution is composed of the exact solutions of RP(i-1, i) and RP(i, i+1). We denote this exact solution by V_i^{n+1} . Note that $V_i^{n+1}(x, t_{n+1})$ depends on $x(x_i < x < x_{i+1})$; it is not constant, in general. In fact, there may be strong discontinuities transversing cell i. In order to advance the numerical solution in time, a procedure to update U_i^n to U_i^{n+1} is required. The Random Choice Method ([4], [6]) takes

$$U_{i}^{n+1} = V_{i}^{n+1}(Q_{i})$$
 (46)

where $Q_i = (x_i + \theta_n \Delta x, t_n + \Delta T)$ is a point at a "random" position within cell i. Here θ_n is a pseudo-random number in the interval [0,1].

We remark that a more well known version of RCM advances the solution in two steps using a staggered grid [6]. The one-step RCM on a non-staggered grid as presented here is simpler to implement and has a number of advantages over the staggered-grid version. This is most evident when source terms depending on x and t are incorporated; also when using higher-order versions [7], or hybrid schemes [8], or irregular grids [9], the one-step RCM facilitates coding enormously.

Two more aspects of the method require attention, namely, the choice of the time-step size ΔT and the generation of the pseudo-random numbers θ_n . The choice of ΔT is dictated by the requirement that no waves should interact. This is the CFL condition. A popular version [4] for RCM is

$$\Delta T = C_S \Delta x / S_{max}$$
 (47)

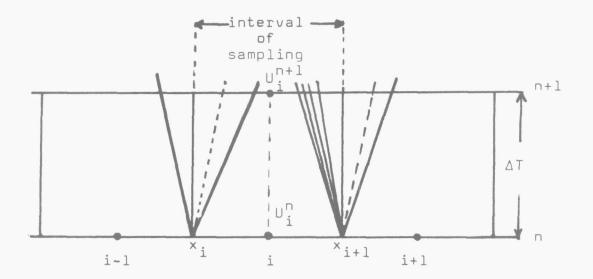

Fig. 4: Solution of local Riemann problems RP(i-1,i) and RP(i,i+1) affecting cell i.

where the coefficient C_S is chosen within the interval (0, $\frac{1}{2}$] and S_{max} is the maximum wave speed present at time t_n , i.e.

$$S_{\text{max}} = \max_{i} \{ |u_i^n| + c_i^n \}$$
 (48)

The CFL condition (47) chooses ΔT in such a way that no wave is allowed to transverse more than half a cell size. This is convenient to implement, but one could do better by monitoring intersection points within each cell and then choosing ΔT appropriately.

Concerning the sequence $\{\theta_n\}$, it has been established [4] that Van der Corput sequences give best results. Truly random numbers are not as adequate. A general Van der Corput sequence [10] $\{\theta_n\}$ depends on two parameters k_1 , k_2 with $k_1 > k_2 > 0$, both integer and relatively prime. Then the (k_1, k_2) van der Corput sequence $\{\theta_n\}$ is formally defined as follows

$$\theta_{n} = \sum_{i=0}^{m} A_{i}k_{1}^{-(i+1)}$$

$$(49)$$

where

$$A_{j} = k_{2}a_{j} \pmod{k_{1}} \tag{50}$$

and

$$n = \sum_{i=0}^{m} a_i k_i^i$$
 (51)

Eq. (49) says that the n-th member $\theta_n \epsilon [0,1]$ of the (k_1, k_2) van der Corput sequence is a summation of m terms involving powers of k_1 . The coefficients A_i are defined by eqs. (50) and (51). First, the nonnegative integer n is expressed in scale of notation with radix k_1 (base k_1) by eq. (51). e.g. $k_1 = 2$ gives the binary expansion of n.

Table I contains coefficients a_i of eq. (51) for $k_1=2$ and $k_1=3$ for ten values of n. The next stage is to find the "modified" coefficients A_i from eq. (50), i.e. A_i is the remainder of dividing k_2a_i by k_1 ($A_i < k_1$). The simplest case is $k_2=1$, then $A_i=a_i$ V_i . Table II(a) shows the coefficients A_i for ten values of n when $k_1=3$ and $k_2=2$. Having found A_i for i=0, . . . , m, the actual members θ_n of the sequence are computed from eq. (49). Table II(b) shows the first 10 members of two van der Corput sequences.

The final stage to implement RCM is the sampling procedure. Fig. 4 shows that the updated value U_i^{n+1} depends on sampling the exact solution of the Riemann problems RP(i-1,i) and RP(i,i+1). Note that for each cell i we only solve one Riemann problem, except for i = 1. Given the CFL condition (47) we sample the right half of the solution of RP(i-1,i) if $0 < \theta_n < \frac{1}{2}$ or the left half of the solution of RP(i,i+1) if $\frac{1}{2} < \theta_n < 1$. The sampling procedure itself, irrespective of the value of θ_n , has two main cases to consider, namely (A) the sampling point Q_i lies to the left of the contact discontinuity $\frac{dx}{dt} = u^*$ and (B) Q_i lies to the right of the contact discontinuity. Each case has two possible wave configurations. Figs. 5 and 6 show these configurations for cases (A) and (B) respectively.

Consider case (A), i.e. Q_i is to the left of $\frac{dx}{dt}$ = u*. The flow chart of Fig. 7 shows the detailed sampling procedure. One proceeds to sample the wave pattern of Fig. 5a if the left wave is a shock wave, i.e. $p^* > p_1$. Otherwise the wave configuration of Fig. 5b is sampled (left rarefaction). For the shock case there are two possible regions, namely behind the shock (region star left) or in front of the shock (left state). For the rarefaction case there are three possible regions. If Q_i lies to the right of the tail of the rarefaction $\frac{dx}{dt} = u^* - c_1^*$, then we assign the solution

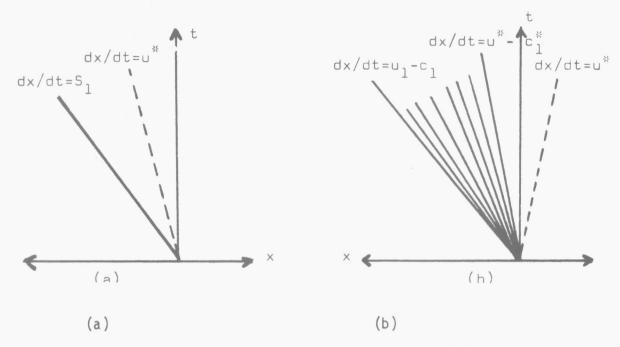

Figure 5: Wave configuration for case A when Q_i is to the left of contact: (a) W_L is shock, (b) W_L is rarefaction.

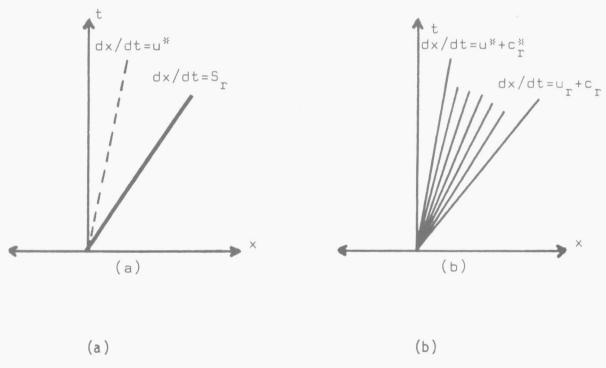

Figure 6: Wave configuration for case B where Q_i is to the right of contact: (a) W_R is shock, (b) W_R is rarefaction.

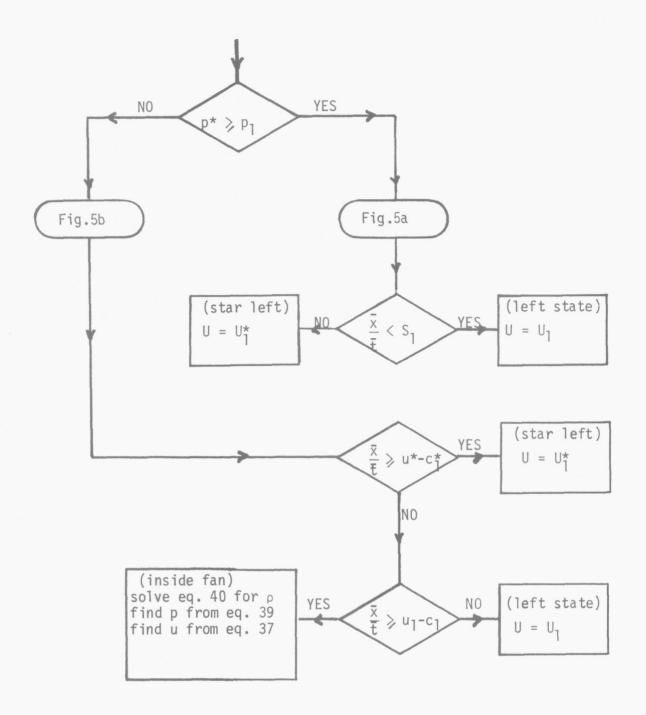

Figure 7: Sampling procedure for case (A), Q_i lies to the left of contact discontinuity $\frac{dx}{dt}$ = u* (see Fig. 5)

corresponding to the region star left. If Q_i lies to the left of the rarefaction head $\frac{dx}{dt} = u_1 - c_1$ then the data state U_1 is assigned to the solution. Finally, if Q_i lies inside the rarefaction fan the non-linear eq. (40) must be solved to find ρ ; the pressure p is found from eq. (39) and the velocity u is found from eq. (37).

Case (B), Q_i lies to the right of the contact discontinuity, is entirely similar to case (A) just described; it is its mirror image (see Fig. 6).

The application of the solution of the Riemann problem with covolume to the Random Choice Method has been described. The resulting numerical technique to solve the one-dimensional unsteady Euler equations with general data and boundary conditions of practical interest can now be applied to a variety of problems in which covolume is important. Note that the present Riemann solver applies directly to the ideal-gas case (b = 0). Indeed, if covolume is not needed, then it is more efficient to exclude covolume in all equations.

In Ref. [3], details of the ideal gas algorithm are given, including FORTRAN programs for the Riemann solver and its implementation in the Random Choice Method.

6. Application to shock-tube problems

Shock-tube problems are special cases of a Riemann problem and can therefore be solved exactly by direct application of the present Riemann solver. Also, as gas dynamical problems they can be solved approximately by solving the Euler equations numerically. This is done here by use of RCM which in turn utilises, locally, the exact solution of the Riemann problem.

First, as a partial validation of the method, we solved the shock-tube problem with data as given in Table IIIa. This is the ideal-gas case (b \equiv 0) and has a similarity solution. Fig. 8 shows results. They are coincident, as they should be. The second shock-tube problem is defined by data of Table IIIb. This is a case with covolume. Fig. 9 shows a comparison between the ideal case (b \equiv 0) and the non-ideal case (b \equiv 10⁻³ m³/kg).

Differences are relatively small. The ideal gas case gives a stronger shock but a weaker contact discontinuity. Also the rarefaction for the ideal case is slightly weaker, but overall variations in ρ , u, p inside the rarefaction fan are small. Variation in internal energy are appreciable. This

has implications for ignition criteria.

Fig. 10 shows a comparison between the exact solution and the numerical solution (obtained by RCM) of the covolume shock tube problem.

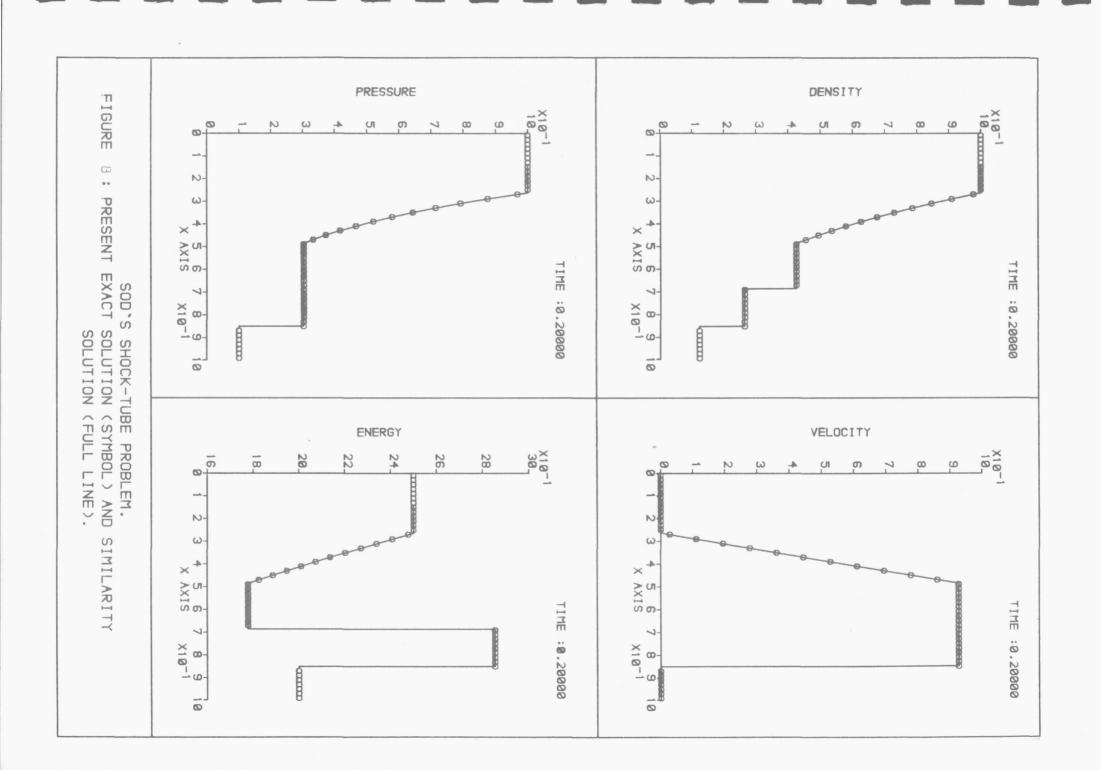

(a) ideal case	(b) non-ideal case
$b = 0.0$ $\gamma = 1.4$	b = 0.001 (m ³ /kg) $\gamma = 1.3$
$ \rho_1 = 1.0 $, $\rho_{r_1} = 0.125$ $ u_1 = 0.0 $, $u_r = 0.0$ $ \rho_1 = 1.0 $, $\rho_r = 0.1$ $ x_0 = 0.4 $	$\rho_1 = 100.0$ $\rho_r = 1.0$ (kg/m ³) $u_1 = 0.0$ $u_r = 0.0$ (m/s) $p_0 = 100.0$ $p_r = 0.1$ (MPa) $x_0 = 0.4$

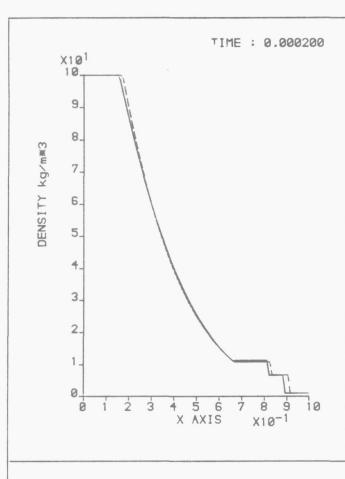

Table III: Data for two shock-tube problems.

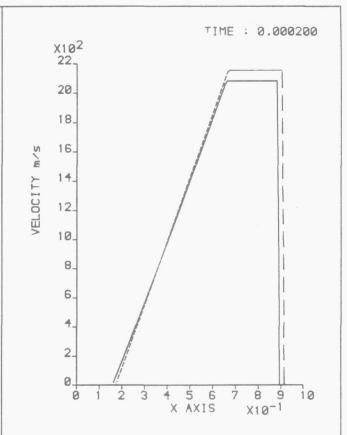

7. Conclusions

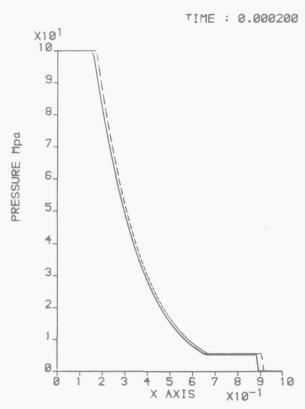

An efficient method for solving exactly the Riemann problem with constant covolume has been presented. The Riemann solver can be directly applied to shock-tube problems. The corresponding ideal-gas version of the Riemann solver is very fast by current standards, Ref. [3].

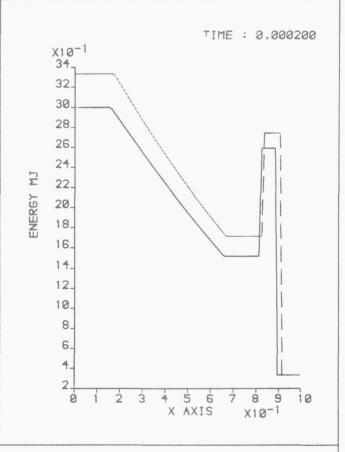

The solution has been applied to the Random Choice Method to solve numerically the general initial boundary value problem for the unsteady one-dimensional Euler equations with the constant covolume equation of state.

APPENDIX

A FORTRAN 77 program for the Random Choice Method using the constant covolume Riemann solver is included.

There is a DRIVER (main program) and a set ofsevenoubroutines.

DRIVER Program

There are 3 one-dimensional arrays for density D, velocity U and pressure P. Also there is an array RN that holds the random numbers required for the calculations; if more than 10000 time steps are required then its dimension will have to be changed. The common block CPGAMMA contains various constants involving the ratio of specific heats GAMMA. STATES contains data for Riemann problem RP(U_{ℓ},U_{ℓ}). STARSO contains solution u* and p* of Riemann problem as well as sound speeds c_{ℓ} and c_{ℓ} . COVOLU contains expressions involving the covolume B and B itself. GAMTOL has GAMMA and the tolerance TOL.

The following data is read in:

TUBLEN: length

M : It defines spatial discretion (e.g. M=100)

NOTIST : Number of time steps (e.g. 200)

NOPROF : No. of profiles (times) to be printed out (e.g. 10)

TOL : Tolerance for iterative solution procedures.

CFLCOE : Coefficient for CFL - condition (0<CFLCOE<½) in calculating time

step size AT.

GAMMA : Ratio of specific heats γ (e.g. 1.3)

B : covolume (e.g. 0.001m³/kg)

Main loop 0001 is for time stepping. Loop 0003 solve M+1 Riemann problems and updates solution by sampling Riemann problem solutions.

Also, there are the following subroutines:

SUBROUTINES RPCOV - this is our Riemann solver for the constant covolume equation of state.

SUBROUTINE SAMCOV - it samples solution of Riemann problem RP(U_{ℓ} , U_{r}). SUBROUTINE RARFAN - computes quantities inside rarefaction fans. It solves iteratively for density ρ first.

SUBROUTINE VDCK12 - this generates random number sequences (k_1, k_2) starting at NRNØ.

SUBROUTINE ICDATA - gives initial condition and calculates various constants to be used throughout the computations. SUBROUTINE CFLCON - calculates ΔT according to CFL condition. SUBROUTINE OUTPUT - it prints out ρ ,u,p and e for specified times.
