(Received 28 November 2006; accepted 26 June 2007; published online 7 September 2007)

We present an analytical expression for the observed signal in time- and phase-resolved pump-probe studies, with particular emphasis on terahertz time-domain spectroscopy. Maxwell’s equations are solved for the response of damped, harmonic oscillators to a driving probe field in the perturbative regime. Our analytical expressions agree with the one previously reported in the literature [Nemec et al., J. Chem. Phys. 122, 104503 (2005)] in the Drude limit; however, they differ in the case of a vibrational resonance. © 2007 American Institute of Physics. [DOI: 10.1063/1.2761915]

I. INTRODUCTION

The use of ultrafast lasers to unravel the dynamics of physical and chemical processes in a variety of systems, ranging from gas-phase dipoles and liquids to monolayers on substrates, is becoming increasingly widespread. The essence of such studies is that the system is brought out of its ground state by an ultrashort excitation pulse (“pump” pulse) and that the relaxation to the (new) equilibrium is followed real time by a second (“probe”) pulse, which can be variably delayed with respect to the first.

In most of these experiments, the temporally integrated intensity of the probe pulse is recorded with a square law detector. As such, the phase information contained in the time-dependent probe field is lost. However, the phase of the field contains information about transient changes in the complex conductivity that is complementary to that contained in the amplitude of the field envelope. In phase-resolved experiments, one detects both the amplitude and phase shift of all components contained in the probe field either through a gating technique (e.g., time-resolved terahertz spectroscopy2–12) or through heterodyning the signal (e.g., two-dimensional infrared13 or interferometric photoelectron spectroscopy14). Though we concentrate here on the experimental analysis of time-resolved terahertz spectroscopy (TRTS)—Refs. 2–10 and 15–18 provide a partial overview of this field—the equations we derive can in principle be applied to any phase-resolved spectroscopy. In addition to the explicit consideration of the phase, the theoretical treatment of these experiments also has to take into account the varying sample response over the range of frequency components contained within the probe pulses.

There have been a number of notable previous efforts in this area, ranging from numerical (e.g., using the finite-difference time-domain pulse propagation method to simulate time-resolved terahertz experiments19) to analytic approaches with varying degrees of complexity.20–22 More recently, a quite general analytical theory was developed by Nemec et al. showing how to extract the transient (third order) conductivity from the experimental data without ad hoc assumptions.23 Subsequent publications from the same group showed how to interpret the measured data in the framework of the most frequently used models.1,24

In this contribution we further generalize the above mentioned work,1,23,24 specifically to accommodate lifetimes of the excited state that are small compared with its scattering time.

II. EXPERIMENTAL SETUP

The central features of a TRTS experimental setup are shown schematically in Fig. 1. A single laser beam is divided into three parts: (i) a pump beam, used to photoexcite the sample; (ii) a generation beam, to generate a terahertz pulse in either a nonlinear crystal25 or a biased emitter,26 and (iii) a delay line.
detection beam, to detect the time-dependent wave form of the transmitted terahertz pulse by electro-optical sampling or using a semiconductor antenna. These three beams can be delayed separately, though only two of the three delays are independent as far as the experimental results are concerned.

The pump-induced differential terahertz field $\Delta E(z,t,t_g)$ at spatial coordinate $z$, and times $t = t_d - t_g$ and $t_e = t_p - t_g$ as defined in Fig. 1, is determined by the temporal response of the material after photoexcitation. However, when material properties change on a time scale that is comparable to the terahertz pulse duration, and different sample properties are probed by the front and tail of the terahertz pulse, the analysis is nontrivial. One of the simplest such cases to consider in transient terahertz experiments is that of a semiconductor photoexcited with a femtosecond laser pulse. This leads to a gas of mobile electrons in the conduction band of the semiconductor, the density of which first increases due to photoexcitation and then decreases due to trapping and recombination. When the time scales of the generation and decay of these mobile electrons are comparable to or faster than the duration of the terahertz pulse, it is very challenging to extract the transient photoconductivity response from the experimentally determined terahertz spectrum.

III. APPROXIMATIONS AND ASSUMPTIONS

The main approximation we make in our analysis is in assuming a small, perturbative response of the system to the pump pulse; this corresponds to neglecting the interaction between the pump-induced dipoles. In the absence of the exciting pump pulse, the terahertz wave form $E_0(z,t)$ induces a polarization $P_0(z,t)$ in the sample. Due to the pump a small but significant fraction of ground-state electrons are excited, and consequently the polarization induced by the terahertz wave form changes, thus giving rise to a change in the propagated wave form $\Delta E(z,t,t_g)$. The specific response of photogenerated charge carriers to the terahertz field is contained within $\Delta E(z,t,t_g)$, which therefore contains information about the charge dynamics. The perturbative approximation applies as long as $\Delta E(z,t,t_g) \ll E(z,t_0)$ throughout the sample, which requires the radiation of the pump-induced dipoles to be sufficiently small, and the sample sufficiently thin for the accumulated phase lag between the electric fields with and without pump to remain close to zero. Then the disturbances $\Delta E$ and $\Delta P$ are linearly proportional both to the probe field and to the excitation intensity.

Other assumptions made in the analysis are (i) that the medium is isotropic, such that the electric and magnetic fields have a linear and mutually orthogonal polarization throughout the beam path; (ii) that the sample is spatially homogeneous, with a material response depending on frequency only; (iii) that the sample thickness exceeds both the dimension of the terahertz wave packet and that of the penetration depth of the pump beam (that is to say, we assume that 100% of the pump light is absorbed in the sample, and that multiple reflections within the sample do not interfere temporally with the main transmitted wave packet); (iv) that there is no dispersion of the pump beam in the sample; (v) that the excited states can be described by a collection of damped harmonic oscillators with identical force constants (i.e., we do not consider inhomogeneous line broadening); and (vi) that the excited charge density decays monexponentially, as in a first order recombination process. These approximations still allow for an analytical treatment, without loosing applicability to a wide range of experimental studies.

IV. MAXWELL’S EQUATIONS

Consider Maxwell’s equations for electromagnetic propagation along a single spatial coordinate $z$, with the electric field $E(z,t,t_g)$ and polarization $P(z,t,t_g)$ polarized along the $x$ axis, and the magnetic field $H(z,t,t_g)$ along the $y$ axis. All involved fields depend parametrically on the delay times $t_p$, $t_g$, and $t_e$ for the pump, generation, and detection delays, respectively (see Fig. 1), with the definitions $t = t_d - t_g$ and $t_e = t_p - t_e$. In SI units Maxwell’s equations read

$$\frac{\partial E(z,t,t_g)}{\partial t} + \frac{\partial P(z,t,t_g)}{\partial t} + \frac{\partial H(z,t,t_g)}{\partial z} = 0,$$

$$\frac{\partial H(z,t,t_g)}{\partial t} + \frac{\partial E(z,t,t_g)}{\partial z} = 0.$$

The detector response equation relates the electric field in the sample to the measured electric field $E_{\text{meas}}(z,t,t_e)$ by means of the detector response function $\psi(t)$,

$$E_{\text{meas}}(z,t,t_e) = \theta(t + T_{\text{win}})\theta(T_{\text{win}} - t) \times \int_0^\infty dt' \psi(t') E(z,t - t',t_e),$$

with $\theta(\tau)$ as the Heaviside’s unit step function vanishing for $\tau < 0$. The two step functions determine the time window within which the terahertz field is sampled. Both the time window and the detector response function limit the resolution of the terahertz measurements.

The polarization in the sample follows directly from the average positions of the charges $x_i(t,t_e)$ and their effective charges $q_i$,

$$P(z,t,t_e) = V^{-1} \sum_{i=1}^{N_i} q_i x_i(t,t_e),$$

with $V$ the volume of the sample and $N_i$ the total number of dipoles. A small fraction of these dipoles are excited by the pump light, their number being $N_e$. The remaining dipoles $(N_i - N_e)$ are not affected by the pump light. Quite generally, the polarization can be written as a Green’s function integral over past times as follows:

$$P(z,t,t_e) = V^{-1} \int dt' E(z,t',t_e) \sum_{i=1}^{N_i} \frac{q_i^2}{m_i} G_i(t - t',t_e),$$

with $G_i(t - t',t_e)$ as the response of the $i$th dipole to an instantaneous impulse $\delta(t - t')$, $q_i$ its effective charge, and $m_i$ its mass. For the ground-state dipoles the temporal evolution is determined by a single Green’s function $G_0(t - t')$, i.e., this function does not have a particle index $i$. The exact expres-
sions for these Green’s functions follow from Eqs. (8) through (10) below. Excited-state dipoles each have their own response, depending on how long they persist in their excited state, before relaxing back to the ground state. Using the differential field \( \Delta E(z, t, t_e) = E(z, t, t_e) - E_0(z, t) \), the polarization can now be separated into three terms,

\[
P(z, t, t_e) = V^{-1} \int dt' E(z, t', t_e) \\
\times \left\{ \sum_{i=1}^{N_e} \frac{q_e^2}{m_g} G_i(t' - t_e) + \sum_{i=1}^{N} \frac{q_i^2}{m_i} G_i(t - t_e) \right\} \\
= P_0(z, t) + \rho_e \int dt' \Delta E(z, t', t_e) \frac{q_e^2}{m_g} G_e(t - t') \\
+ \Delta P(z, t, t_e),
\]

with the total particle density \( \rho = N_e/V \), and

\[
\Delta P(z, t, t_e) = \int dt' E(z, t', t_e) \\
\times \left\{ \sum_{i=1}^{N_e} \frac{q_e^2}{m_i} G_i(t' - t_e) - \rho_e \frac{q_e^2}{m_g} G_e(t' - t_e) \right\},
\]

\[
P_0(z, t) = \rho_i \int dt' E_0(z, t') \frac{q_e^2}{m_g} G_e(t - t'),
\]

with \( \rho_e = N_e/V \). The perturbative limit mentioned in the previous section implies that the full electric field in Eq. (6) is replaced by the primary field (the electric field in the absence of sample excitation by a pump pulse),

\[
\Delta P(z, t, t_e) = \int dt' E_0(z, t') \\
\times \left\{ \sum_{i=1}^{N_e} \frac{q_e^2}{m_i} G_i(t' - t_e) - \rho_e \frac{q_e^2}{m_g} G_e(t' - t_e) \right\},
\]

\[
x_e(t, t_e, \tau) = \theta(t_e - t) \frac{q_e}{m_g} \int dt' E_0(t') G_e(t - t') \\
+ \theta(t_e + \tau - t) \theta(t - t_e) \times \left\{ \frac{q_e}{m_e} \int dt' E_0(t') G_e(t - t') - e(t, t_e) \right\} \\
+ \theta(t - t_e - \tau) \left\{ \frac{q_e}{m_g} \int dt' E_0(t') G_e(t - t') + g(t, t_e, \tau) \right\},
\]

where \( e(t, t_e) \) and \( g(t, t_e, \tau) \) are solutions of the homogeneous equations of motion (see Appendix), with amplitudes determined by the condition that the particle motion is continuous both at the time of excitation \( t_e \) and that of decay back into the ground state, \( t_e + \tau \). Analogously, we define the time-dependent effective charge,
These terms have a straightforward interpretation:

\[ q_e(t, t_e, \tau) = \theta(t_e - t) q_e + \theta(t_e + \tau - t) \theta(t - t_e) q_e + \theta(t - t_e - \tau) q_e. \]  
(13)

This allows for different coupling strengths of the vibrational modes with the driving field, depending on the state (excited or ground) of the oscillator. The average behavior of all excited dipoles is determined by the temporal profile of \( \rho_e(t) \), the density of excited states. In the following we assume it has an exponential decay rate \( \Gamma = 1/\tau_e \):

\[ \rho_e(t) = \rho_e e^{-\Gamma t} \theta(t). \]  
(14)

The polarization follows as a weighted average of the individual dipoles, each with their own lifetime \( \tau \),

\[ \Delta P(t, t_e) = \int_0^\infty d\tau \rho_e(\tau) \{ q_e(t, t_e, \tau) x_e(t, t_e, \tau) - q_e x_e(t) \}. \]  
(15)

It is shown in the appendix that the differential polarization can be written as a sum of three terms,

\[ \Delta P(t, t_e) = \Delta P_{\text{driven}}(t, t_e) + \Delta P_{\text{excitation}}(t, t_e) + \Delta P_{\text{decay}}(t, t_e). \]  
(16)

These terms have a straightforward interpretation:

(i) the term \( \Delta P_{\text{driven}}(t, t_e) \) corresponds to the driven motion of the oscillators in their excited state, during the time interval \( t_s < t < t_e + \tau \);

(ii) the term \( \Delta P_{\text{excitation}}(t, t_e) \) corresponds to the damped transients (free induction decay) created at the time of excitation \( t = t_e \); and

(iii) the term \( \Delta P_{\text{decay}}(t, t_e) \) corresponds to the damped transients created at the (exponentially distributed) times of decay \( t = t_e + \tau \).

Using the Fourier convention,

\[ f(\omega) = \int dt e^{i \omega t} f(t), \]
\[ f(t) = \frac{1}{2\pi} \int d\omega e^{-i \omega t} f(\omega), \]  
(17)

the first two terms can be Fourier transformed to

\[ \Delta P_{\text{driven}}(\omega, \omega_e) + \Delta P_{\text{excitation}}(\omega, \omega_e) = E_0(\omega + \omega_e) \rho_e \Gamma G_g(\omega + \omega_e) \frac{q_e}{m} \left[ \left\{ -1 - \frac{q_e}{G_g(\omega + \omega_e)} \right\} G_e(\omega + i\Gamma) \right], \]  
(18)

and the third to

\[ \Delta P_{\text{decay}}(\omega, \omega_e) = E_0(\omega + \omega_e) \rho_e \Gamma G_g(\omega + \omega_e) \left[ \frac{q_e}{m} \right] \left[ \left\{ -1 - \frac{q_e}{G_g(\omega + \omega_e)} \right\} G_e(\omega + i\Gamma) \right]. \]

VI. DRUDE ELECTRON GAS

The above expressions apply to a driven, damped oscillator, which is temporarily excited into a state with different oscillator characteristics. That is to say, it does not apply to a Drude electron gas. However, our formalism is suitable to describe this case too. This is important for the interpretation of broadband pump-probe terahertz experiments, which probe interferences of the Drude electron gas and vibrational resonances. In this section we show what response may be expected from Drude electrons with finite lifetime \( \tau_e = 1/\Gamma_e \).

The electron cloud is created at time \( t = t_e \) with (by definition) zero position and zero average velocity. After recombination with an ion to a neutral excited state, the Drude electron does not contribute to the photoinduced current anymore. Consequently, the position of a Drude electron with lifetime \( \tau \) is “frozen” from time \( t = t_e + \tau \) onwards,

\[ x_e(t, t_e, \tau) = \frac{q_e}{m_e} \theta(t_e + \tau - t) \theta(t - t_e) \times \int_{t_e}^{t_e + \tau} dt' E_0(t') G_p(t - t') + \theta(t - t_e - \tau) \times \int_{t_e}^{t_e + \tau} dt' E_0(t') G_p(t_e + \tau - t'). \]  
(21)

Here the Drude Green’s function \( G_p(t) \) is a solution of Eqs.
(8) and (9) in the case of vanishing resonance frequency ($\omega_{\text{res}}=0$),

$$G_D(t) = \frac{\theta(t)}{\gamma_D} (1 - e^{-\gamma_D t}),$$

(22)

with $\gamma_D$ as the scattering time of the Drude electrons. Equation (21) cannot be Fourier transformed easily because the second term does not vanish for $t \to \infty$. However, its derivative with respect to the first time variable $t$,

$$\dot{x}_e(t, t, t) = \frac{q_e}{m_e} \theta(t_e + t - t) \theta(t - t_e) \int_{t_e}^{t} dt' E_0(t') \dot{G}_D(t - t'),$$

(23)

can be Fourier transformed without the problem of divergences. The resulting photoinduced current reads

$$\Delta J_{\text{Drude}}(\omega, \omega_v) = E_0(\omega + \omega_v) \Delta \sigma_{\text{Drude}}(\omega, \omega_v),$$

(24)

$$\Delta \sigma_{\text{Drude}}(\omega, \omega_v) = \frac{q_e^2}{m} \frac{\rho_e}{(\Gamma + i \omega_v)(\Gamma + \gamma_D - i \omega)}$$

in agreement with Eq. (33) in Ref. 1. In comparing these expressions, please note that our couple $(\omega_v, \omega)$ corresponds to their $(-\omega_v, \omega)$, as a result of different definitions both in the delay times and in the Fourier transform.

VII. SPATIAL DEPENDENCE

We now turn our attention to the spatial part of the problem. Using the Fourier convention of Eq. (17) we obtain for Eq. (1) the well-known expressions

$$\frac{\partial H(z, \omega, t_e)}{\partial z} = i \omega \{ E_0(z, \omega, t_e) + P(z, \omega, t_e) \},$$

$$\frac{\partial E(z, \omega, t_e)}{\partial z} = i \omega \mu_0 H(z, \omega, t_e).$$

(25)

In the absence of excitation, these equations read

$$\frac{\partial H_0(z, \omega)}{\partial z} = i \omega \{ \epsilon_0 E_0(z, \omega) + P_0(z, \omega) \}$$

$$= i \omega \epsilon_0 E_0(z, \omega) \{ 1 + \chi_0(\omega) \},$$

(26)

$$\frac{\partial E_0(z, \omega)}{\partial z} = i \omega \mu_0 H_0(z, \omega),$$

with the polarization of Eq. (5) written as follows:

$$P(z, \omega, t_e) = P_0(z, \omega) + \epsilon_0 \chi_0(\omega) \Delta E(z, \omega, t_e) + \Delta P(z, \omega, t_e),$$

(27)

$$P_0(z, \omega) = \epsilon_0 \chi_0(\omega) E_0(z, \omega).$$

The susceptibility is linearly related to the ground-state Green’s function,

$$\epsilon_0 \chi_0(\omega) = \frac{q_e^2}{m} G_0(\omega),$$

(28)

in agreement with Eq. (6). Subtracting Eq. (26) from Eq. (25) yields the following equation for the difference fields:

$$\frac{\partial \Delta H(z, \omega, t_e)}{\partial z} = \epsilon_0 \Delta E(z, \omega, t_e) \{ 1 + \chi_0(\omega) \} + i \omega \Delta P(z, \omega, t_e),$$

$$\frac{\partial \Delta E(z, \omega, t_e)}{\partial z} = i \omega \mu_0 \Delta H(z, \omega, t_e).$$

(29)

The separation of the total polarization into three terms as proposed in Eq. (27) has the important consequence that the differential fields $\Delta E$ and $\Delta H$ propagate with the same dielectric constant $\epsilon_0 \{ 1 + \chi_0(\omega) \}$ as the primary fields $E_0$ and $H_0$, the only difference being the source term $\Delta P(z, \omega, t_e)$. The three polarization terms can be interpreted as follows: $P_0$ is the response of $N_g$ ground-state dipoles (i.e., as if none of them had been excited by the pump) to the primary field $E_0$; $\epsilon_0 \chi_0(\omega) \Delta E(z, \omega, t_e)$ is the response of $N_e$ ground-state dipoles to the differential field, and these two terms together describe the response of $N_e$ ground-state dipoles to the total field; the third term, the differential polarization $\Delta P$, describes the response of $N_e$ excited-state dipoles to the total field, minus the response of $N_g$ ground-state dipoles, thereby correcting for the fact that the first two terms assume $N_g$ ground-state dipoles instead of $N_e - N_g$.

Moreover, the fields can be separated into a pump-free part describing the medium in the absence of a pump field, and a differential part ($\Delta E$) describing the response to an exciting pump field. We write, for $z \leq 0$,

$$E(z, \omega, t_e) = E_{\text{in}}(z, \omega) + E_{\text{ref}}(z, \omega) + \Delta E_{\text{ref}}(z, \omega, t_e),$$

$$H(z, \omega, t_e) = H_{\text{in}}(z, \omega) + H_{\text{ref}}(z, \omega) + \Delta H_{\text{ref}}(z, \omega, t_e),$$

(30)

$$P = 0.$$
\[ E(z, \omega, t_e) = E_{in}(z, \omega) + \Delta E_{u}(z, \omega, t_e) + \Delta E_{r}(z, \omega, t_e) + \Delta E_{f}(z, \omega, t_e), \]
\[ H(z, \omega, t_e) = H_{in}(z, \omega) + \Delta H_{u}(z, \omega, t_e) + \Delta H_{r}(z, \omega, t_e) + \Delta H_{f}(z, \omega, t_e), \]
\[ P(z, \omega, t_e) = \varepsilon_0 \chi_3(\omega) E(z, \omega, t_e) + \Delta P(z, \omega, t_e). \]

In general the polarization causes radiation in both the forward and backward directions. For the stationary case (without pump) the effects of the forward and backward radiated fields are fully taken into account by the index of refraction, resulting in a reflected field component at the air-sample interface. In the time-dependent case (with pump) the polarization produces a forward radiated electromagnetic field \( \Delta E_{\text{forw}} \) and a backward radiated field \( \Delta E_{\text{back}} \), respectively [see Fig. 2(b)]. On impinging onto the entrance interface of the sample, the backward traveling wave gives rise to a (backward) transmitted part, represented by the field \( \Delta E_{\text{ref}} \) Eq. (30), and a (forward) reflected part, represented by the field \( \Delta E_{\text{u}} \) in Eq. (31).

Equations (25)–(31) lead to several derived expressions, which we subdivide into four cases: with and without pumping, and before and after the interface. One obtains:

(i) without pumping, before the interface \((z < 0)\),
\[ \frac{\partial E_{\text{in}}(z, \omega)}{\partial z} = i\omega \mu_0 H_{\text{in}}(z, \omega), \]
\[ \frac{\partial H_{\text{in}}(z, \omega)}{\partial z} = i\omega \varepsilon_0 E_{\text{in}}(z, \omega), \]
\[ \frac{\partial E_{\text{ref}}(z, \omega)}{\partial z} = i\omega \mu_0 H_{\text{ref}}(z, \omega), \]
\[ \frac{\partial H_{\text{ref}}(z, \omega)}{\partial z} = i\omega \varepsilon_0 E_{\text{ref}}(z, \omega); \]

(ii) without pumping, after the interface \((z > 0)\),
\[ \frac{\partial E_{\text{u}}(z, \omega)}{\partial z} = i\omega \mu_0 H_{\text{u}}(z, \omega), \]
\[ \frac{\partial H_{\text{u}}(z, \omega)}{\partial z} = i\omega \varepsilon_0 (1 + \chi_3(\omega)) E_{\text{u}}(z, \omega), \]

where the boundary conditions for the air-sample interface imply
\[ E_{\text{u}}(0, \omega) + E_{\text{ref}}(0, \omega) = E_{\text{in}}(0, \omega), \]
\[ H_{\text{u}}(0, \omega) + H_{\text{ref}}(0, \omega) = H_{\text{in}}(0, \omega); \]

(iii) with pumping, before the interface \((z < 0)\),
\[ \frac{\partial E_{\text{ref}}(z, \omega, t_e)}{\partial z} = i\omega \mu_0 \Delta H_{\text{ref}}(z, \omega, t_e), \]
\[ \frac{\partial H_{\text{ref}}(z, \omega, t_e)}{\partial z} = i\omega \varepsilon_0 \Delta E_{\text{ref}}(z, \omega, t_e); \]

(iv) with pumping, after the interface \((z > 0)\),
\[ \frac{\partial E_{\text{u}}(z, \omega, t_e)}{\partial z} = i\omega \mu_0 \Delta H_{\text{u}}(z, \omega, t_e), \]
\[ \frac{\partial H_{\text{u}}(z, \omega, t_e)}{\partial z} = i\omega \varepsilon_0 (1 + \chi_3(\omega)) E_{\text{u}}(z, \omega, t_e), \]
\[ \frac{\partial \Delta E_{\text{back}}(z, \omega, t_e) + \Delta E_{\text{forw}}(z, \omega, t_e)}{\partial z} = i\omega \mu_0 \Delta H_{\text{back}}(z, \omega, t_e) + \Delta H_{\text{forw}}(z, \omega, t_e), \]
\[ \frac{\partial \Delta H_{\text{back}}(z, \omega, t_e) + \Delta H_{\text{forw}}(z, \omega, t_e)}{\partial z} = i\omega \varepsilon_0 (1 + \chi_3(\omega)) \times \{ \Delta E_{\text{back}}(z, \omega, t_e) + \Delta E_{\text{forw}}(z, \omega, t_e) \}
+ i\omega \Delta P(z, \omega, t_e), \]

with the corresponding boundary conditions,
\[ \Delta E_{\text{ref}}(0, \omega, t_e) = \Delta E_{\text{u}}(0, \omega, t_e) + \Delta E_{\text{back}}(0, \omega, t_e), \]
\[ \Delta H_{\text{ref}}(0, \omega, t_e) = \Delta H_{\text{u}}(0, \omega, t_e) + \Delta H_{\text{back}}(0, \omega, t_e). \]

Equations (32)–(34) (without pumping) are solved by the well-known expressions
\[ E_{\text{in}}(z, \omega) = E_{\text{in}}(0, \omega) e^{i\omega z / c}, \]
\[ H_{\text{in}}(z, \omega) = \varepsilon_0 E_{\text{in}}(0, \omega) e^{i\omega z / c}, \]
\[ E_{\text{ref}}(z, \omega) = E_{\text{ref}}(0, \omega) e^{-i\omega z / c}, \]
\[ H_{\text{ref}}(z, \omega) = -\varepsilon_0 E_{\text{ref}}(0, \omega) e^{-i\omega z / c}, \]
\[ E_{\text{u}}(z, \omega) = E_{\text{u}}(0, \omega) e^{i\omega n(\omega) z / c}, \]
\[ H_{\text{u}}(z, \omega) = \varepsilon_0 H_{\text{u}}(0, \omega) e^{i\omega n(\omega) z / c}, \]
\[ E_{\text{u}}(0, \omega) = \frac{2}{1 + n(\omega)} E_{\text{in}}(0, \omega), \]
\[ E_{\text{ref}}(0, \omega) = \frac{1 - n(\omega)}{1 + n(\omega)} E_{\text{in}}(0, \omega), \]

with the index of refraction \( n(\omega) \) defined by the relation \( n^2(\omega) = 1 + \chi_3(\omega) \). Likewise, Eqs. (35)–(37) for the pump-induced field changes are solved by
the fields radiated by the polarized dipoles are defined by

\[ \Delta E_{\text{ref}}(z, \omega, t_p) = \Delta E_{\text{ref}}(0, \omega, t_p) e^{-i\omega t_p / c}, \]

\[ \Delta H_{\text{ref}}(z, \omega, t_p) = -c \varepsilon_0 \Delta E_{\text{ref}}(0, \omega, t_p) e^{-i\omega t_p / c}, \]

\[ \Delta E_{u}(z, \omega, t_p) = \Delta E_{u}(0, \omega, t_p) e^{i\omega_0 z / c}, \]

\[ \Delta H_{u}(z, \omega, t_p) = c \varepsilon_0 \Delta E_{u}(0, \omega, t_p) e^{i\omega_0 z / c}, \]

\[ \Delta E_{u}(0, \omega, t_p) = \frac{n(\omega) - 1}{n(\omega) + 1} \Delta E_{\text{back}}(0, \omega, t_p), \]

\[ \Delta E_{\text{ref}}(0, \omega, t_p) = \frac{2n(\omega)}{n(\omega) + 1} \Delta E_{\text{back}}(0, \omega, t_p), \]

\[ \Delta E_{\text{back}}(z, \omega, t_p) + \Delta E_{\text{frown}}(z, \omega, t_p) = \int dz' \Delta P(z', \omega, t_p) e(z - z', \omega), \]

\[ \Delta H_{\text{back}}(z, \omega, t_p) + \Delta H_{\text{frown}}(z, \omega, t_p) = \int dz' \Delta P(z', \omega, t_p) h(z - z', \omega). \]

The Green’s functions \( e(z, \omega) \) and \( h(z, \omega) \) used to calculate the fields radiated by the polarized dipoles are defined by

\[ e(z, \omega) = \frac{i \omega \mu_0 c}{2n(\omega)} e^{i\omega_0(z/c)} \]

\[ h(z, \omega) = \frac{1}{2z} e^{i\omega_0(z/c)}, \]

providing the solution to the equations

\[ \frac{\partial e(z, \omega)}{\partial z} = i \omega \mu_0 h(z, \omega), \]

\[ \frac{\partial h(z, \omega)}{\partial z} = i \omega \varepsilon_0 n(\omega) e(z, \omega) + \Delta e(z). \]

We now consider the spatiotemporal dependence of the density of excited states, \( \rho_s(z, t) \). In the case of a finite duration of the pump pulse the excited-state population is determined by the relation

\[ \frac{\partial}{\partial t} \rho_s(z, t) = S(z, t) - \Gamma \rho_s(z, t). \]

The rate of charge carrier production, \( S(z, t) \), is given by

\[ S(z, t) = \rho_s(\theta(z) e^{-\alpha z} I(t - n_p z/c), \]

with \( \alpha \) the reciprocal penetration depth of the pump beam, and \( I(t - n_p z/c) \) the intensity profile of the pump beam propagating through the sample assume without dispersion and a corresponding group velocity \( c/n_p \). The “effective index of refraction for group propagation” \( n_p \) is related to the index of refraction \( n(\omega) \) as

\[ n_p = n(\omega_p) - \omega_p \left( \frac{dn(\omega)}{d\omega} \right)_{\omega_p}, \]

with \( \omega_p \) as the center radial frequency of the pump beam. In frequency domain the relative density of excited dipoles can be written as follows:

\[ \rho_s(z, \omega) = \rho_s(\omega) \left( \frac{I(\omega) \theta(z)}{\delta(\omega) - \alpha + i \omega_p z/c} \right), \]

with \( \rho_s(\omega) = \rho_s(\Gamma - i \omega) \). At this point one has all ingredients to perform the spatial integration over the Green’s functions in Eq. (39). When the sample is thick enough to absorb all the excitation light we do not have to take into account the excitation light profile generated by (backward traveling) pump light reflected off the exit interface of the sample. In the thick-sample approximation the integration limits may be extended to infinity,

\[ \Delta E_{\text{frown}}(z \rightarrow \infty, \omega, q) = \int_0^\infty dz' \Delta P(z', \omega, q) e^{(z - z', \omega)}, \]

\[ \Delta E_{\text{back}}(z = 0, \omega, q) = \int_0^\infty dz' \Delta P(z', \omega, q) e^{-(z - z', \omega)}. \]

Using Eq. (18) for \( \Delta P_{\text{driven}} \), Eq. (45) for \( \rho_s \), Eq. (38) for \( E_u \), Eq. (39) for \( \Delta E_{\text{back}} \), and Eq. (40) for \( e \), we obtain the following solution for the transmitted Terahertz wave

\[ F^{(z)} = \frac{\Delta E(\omega_p)}{E_u(\omega = 0, \omega_p)} \Delta \sigma(\omega_p) \frac{I(-\omega_p)}{2n(\omega)} e^{i\omega_0(z/c)} \]

\[ \times \left[ 1 - \frac{n(\omega) - 1}{n(\omega) + 1} \right] \left[ \frac{1}{F^{(z)}} + \frac{n(\omega) - 1}{n(\omega) + 1} \right]. \]

\[ F^{(z)}(z) = \alpha c - i \omega n_p - i(\omega + \omega_p) n(\omega + \omega_p) \pm i \omega n(\omega), \]

with the conductivity \( \Delta \sigma \) defined above in Eq. (20). For an infinitely long sampling window \( (T_u \rightarrow \infty) \) the measured fields are related to the real fields as [see Eq. (25)]

\[ \frac{\Delta E_{\text{meas}}(\omega_p)}{E_{\text{meas}}(\omega = 0, \omega_p)} = \frac{\psi(\omega)}{\psi(\omega + \omega_p)} \Delta E(\omega, \omega_p). \]

This introduces the detector response into Eq. (47) when written in terms of the measured fields. Different expressions for the spatial factor \( F^{(z)}(z) \) in Eq. (47), applying to thin samples, or to samples with low absorption, can be found in the seminal papers.23

\[ \text{VIII. NUMERICAL VALIDATION} \]

In spite of the simplicity of our model (a driven damped harmonic oscillator) the resulting expressions for the polarization in the frequency domain, Eqs. (18) and (19), are quite cumbersome, and we felt the need to validate them independently by comparing them with straightforward numerical solutions for a specific set of conditions. These conditions are (i) the driving field is a continuous-wave field of the form \( E_0(t) = E_0 \cos \omega_0 t \); (ii) the effective charges in the excited and ground states are equal \( (q_e = q_g) \) such that the polarization [Eqs. (18) and (19)] \( \Delta P(t, t_p) \) is linearly related to the posi-
tion difference of the excited- and ground-state oscillators \( x_e - x_g \); (iii) the resonance frequency of the ground state is one-third the frequency of the driving field; and (iv) the damping rates are equal in the excited and ground states.

The analytical solution for the position in the two-dimensional (2D) time domain was retrieved from the polarization by a one-dimensional numerical Fourier transform from \( \omega \) to \( t \); the transform from \( \omega_e \) to \( t_e \) was done trivially using the delta function of the driving field, \( E_0(\omega + \omega_e) = 2 \pi \delta(\omega + \omega_e) + \delta(\omega - \omega_e - \omega_g) \). The numerical calculations are based on Eqs. (12)–(15), with the Green’s function defined in the Appendix [Eq. (A4)]. The results are plotted in Fig. 3.

The numerical results are indistinguishable from the analytical ones. However, when the decay term \( \Delta P_{\text{decay}} \) is neglected, discrepancies arise. This proves, along with the derivation presented in Sec. V, that our solutions can be trusted.

\[
\Delta J_{dc}(\omega, \omega_e) = \Delta \sigma(\omega, \omega_e) E_{dc}(\omega + \omega_e) = 2 \pi \delta(\omega + \omega_e) \Delta \sigma(\omega, \omega_e) E_0.
\]

(49)

Since a dc field has no phase, in the time domain this current depends on its temporal variables only through the difference \( t-t_e \). This is adequately reflected by the introduction of wiggled, single-variable functions as follows:

\[
\Delta \tilde{J}_{dc}(t) = \Delta J_{dc}(t, 0),
\]

\[
\Delta \tilde{J}_{dc}(t-t_e) = \Delta J_{dc}(t, t_e) = \frac{1}{2 \pi} \int d\omega e^{-i\omega(t-t_e)} \Delta \tilde{J}_{dc}(\omega),
\]

(50)

\[
\Delta \tilde{P}_{dc}(\omega) = E_0 \Delta \sigma(\omega, -\omega).
\]

The integrated current surge follows as

\[
\int_{-\infty}^{\infty} dt \Delta \tilde{J}_{dc}(t-t_e) = \Delta \tilde{J}_{dc}(\omega = 0) = E_0 \Delta \sigma(0, 0).
\]

(51)

On the other hand it can be written in terms of the polarization as

\[
\int_{-\infty}^{\infty} dt \Delta \tilde{J}_{dc}(t-t_e) = \int_{-\infty}^{\infty} dt \left( \frac{d}{dt} \Delta \tilde{P}_{dc}(t-t_e) \right) = \Delta \tilde{P}_{dc}(\infty) - \Delta \tilde{P}_{dc}(-\infty)
\]

(52)

\[
\Delta \tilde{P}_{dc}(t) = \Delta \tilde{P}_{dc}(t, 0).
\]

Since the vibrational motion of the oscillator is identical to its motion in the ground state at the times \( t \sim \pm \infty \), it is clear that the above polarization difference must vanish. Hence we find that, for the vibrational model defined in Sec. V, the 2D-frequency dependent conductivity \( \Delta \sigma(\omega, \omega_e) \) must obey the relation

\[
\Delta \sigma_{\text{vibrational}}(0, 0) = 0.
\]

(53)

This is indeed the case for our vibrational expression, Eq. (20). Relation (53) does not apply to Eq. (50) in Sec. IIIC in Ref. 1. From this we deduce that their model does not describe a vibrational oscillator excited at time \( t=t_e \) and decayed back to the ground state at a later time \( t=t_e+\tau \) with some distribution of finite lifetimes \( \tau \).

Relation (53) does not apply to the Drude conductivity [Eq. (24)] because from Eq. (21) it can be seen that the quantities \( x_e(t \rightarrow \infty, t_e, \tau) \) and \( \Delta \tilde{P}_{dc,\text{Drude}}(t \rightarrow \infty) \) do not vanish.

Finally, we added a decay term to the vibrational conductivity published in the literature.\(^1\) The decay term corresponds to the vibrational motion of an oscillator after the decay of the excited state to the ground state. A numerical calculation confirms our analytical results.

satie voor Wetenschappelijk Onderzoek (NWO).” We are grateful for helpful discussions with Petr Kuzel.

APPENDIX: CONTINUITY CONDITIONS

Equation (12) describes the motion of a damped, driven oscillator \( x_e(t, t_e, \tau) \) during three separate periods. Before the moment of excitation, for \( t < t_e \), the motion of the oscillator is determined by the ground-state dynamics [Eq. (8)]. After excitation, for \( t > t_e \), the oscillator obeys excited-state dynamics [Eq. (10)], until the moment that the excitation spontaneously decays back into the ground state, at \( t = t_e + \tau \). From that moment onwards, the oscillator obeys ground-state dynamics again.

For \( t < t_e \), the solution reads

\[
x_e(t, t_e, \tau) = \theta(t_e - t) \frac{q_e}{m_e} \int_{-\infty}^{t_e} dt' E_0(t') G_e(t - t')
\]  
(A1)

and for \( t_e < t < t_e + \tau \),

\[
x_e(t, t_e, \tau) = \theta(t_e + \tau - t) \theta(t - t_e) \left\{ \frac{q_e}{m_e} \int_{-\infty}^{t_e} dt' E_0(t') G_e(t - t') - e(t, t_e) \right\}
\]  
(A2)

with

\[
e(t, t_e) = e_1(t_e) G_e (t - t_e) + e_2(t_e) \dot{G}_e (t - t_e)
\]  
(A3)

as the homogeneous solution of the excited-state dynamics. Using \( \Omega_e = \sqrt{\alpha_{res,e} + \frac{\gamma_e}{2}} \), the Green’s function for the underdamped case \( (\alpha_{res,e} > \gamma_e/2) \) can be written as

\[
G_e(t) = \theta(t) \frac{\sin \Omega_e t}{\Omega_e} e^{-\gamma_e/2}
\]  
(A4)

with the limits

\[
\lim_{t \to 0} G_e(t) = 0, \quad \lim_{t \to 0} \dot{G}_e(t) = 1, \quad \lim_{t \to 0} \ddot{G}_e(t) = -\gamma_e
\]  
(A5)

where the dot indicates a derivative to the (first) time variable. In the case of overdamped dynamics the sine and cosine functions in Eq. (A4) must be replaced with their hyperbolic siblings, and \( \Omega_{e, overdamped} = \sqrt{\gamma_e^2/4 - \alpha_{res,e}^2} \). Continuity of both position and velocity at \( t = t_e \),

\[
\lim_{t \uparrow t_e} x_e(t, t_e, \tau) = \lim_{t \downarrow t_e} x_e(t, t_e, \tau), \\
\lim_{t \uparrow t_e} \dot{x}_e(t, t_e, \tau) = \lim_{t \downarrow t_e} \dot{x}_e(t, t_e, \tau)
\]  
(A6)

when applied to the solutions (A1) and (A2), results in two conditions for the homogeneous amplitudes \( e_{1,2} \),

\[
\frac{q_e}{m_e} \int dt' E_0(t') G_e(t_e - t') = \frac{q_e}{m_e} \int dt' E_0(t') G_e(t_e - t') - e(t_e, t_e),
\]  
(A7)

Consequently, the amplitudes must have the values

\[
e_1(t_e) = \frac{q_e}{m_e} \int dt' E_0(t') \Delta K(t_e - t') + \gamma_e \Delta K(t_e - t'),
\]  
(A8)

\[
e_2(t_e) = \frac{q_e}{m_e} \int dt' E_0(t') \Delta K(t_e - t'),
\]

with

\[
\Delta K(t) = \frac{q_e}{m_e} G_e(t) - \frac{q_e}{m_g} G_g(t).
\]

In the same way we can derive the coefficients for the solution at times after decay of the excited state \( t > t_e + \tau \),

\[
x_e(t, t_e, \tau) = \theta(t - t_e - \tau) \left\{ \frac{q_e}{m_g} \int dt' E_0(t') G_g(t - t') + g(t, t_e, \tau) \right\}
\]  
(A9)

with

\[
g(t, t_e, \tau) = g_1(t_e) G_g (t - t_e - \tau) + g_2(t_e) \dot{G}_g (t - t_e - \tau)
\]  
(A10)

Continuity at time \( t = t_e + \tau \) yields

\[
\frac{q_e}{m_e} \int dt' E_0(t') G_e(t_e + \tau - t') - e(t_e + \tau, t_e)
\]

\[
= \frac{q_e}{m_e} \int dt' E_0(t') G_g(t_e + \tau - t') + g(t_e + \tau, t_e, \tau),
\]  
(A11)

\[
\frac{q_e}{m_g} \int dt' E_0(t') \dot{G}_g(t_e + \tau - t') \left|_{t_e+\tau} - e(t_e, t_e) \right|_{t_e+\tau}
\]

\[
= \frac{q_e}{m_g} \int dt' E_0(t') \dot{G}_g(t_e + \tau - t') \left|_{t_e+\tau} + \dot{g}(t_e, t_e, \tau) \right|_{t_e+\tau},
\]  
with the corresponding solutions for the homogeneous amplitudes \( g_{1,2}(t_e, \tau) \):
Given the coefficients \( e_1(t_e), e_2(t_e), g_1(t_e, \tau), \) and \( g_2(t_e, \tau) \) of the homogeneous solutions [Eqs. (A3) and (A10)], the position of the excited oscillator [Eq. (12)] is determined at all times \( t, t_e, \) and \( \tau \). Threefold integration over the lifetime \( \tau \) [Eq. (15)], and time delays \( t \) and \( t_e \) [Eq. (17)] yields the polarization in 2D-frequency domain.

The homogeneous amplitudes \( e_1(t_e), e_2(t_e), g_1(t_e, \tau), \) and \( g_2(t_e, \tau) \) need only slight adaptation when a difference in equilibrium position \( \Delta x \) of the excited and ground-state oscillators is taken into account. One needs the following additions to the coefficients:

\[
g_1(t_e, \tau) = \gamma_x \Delta x,
\]

\[
g_2(t_e, \tau) = \Delta x,
\]

\[
e_1(t_e) = \gamma_y \Delta x,
\]

\[
e_2(t_e) = \Delta x.
\]

This results in a fourth term in the total polarization [cf. Eqs. (16), (18), and (19)].

\[
\Delta P_{\text{equilibrium}}(\omega, \omega_e) = 2\pi \Delta x \delta(\omega + \omega_e) p_x E_0(\omega + \omega_e)
\]

\[
\times \left\{ q_x \Gamma G_x(\omega) \left[ \frac{\gamma_x - i\omega}{\Gamma - i\omega} - \left( \gamma_x + \Gamma - i\omega \right) \right] \right. 
\]

\[
\times \left( \frac{\gamma_x + \Gamma - 2i\omega}{G_e(\omega + i\Gamma)} \right) - \frac{q_x}{\Gamma + i\omega_e} 
\]

\[
\times \left[ 1 - \frac{G_e(\omega + i\Gamma)}{G_e(\omega + \omega_e)} \right].
\]

These terms can be readily recognized from the 2D-frequency conductivity due to the delta function (broadened in practice by the time resolution of the experimental setup), yielding diagonal lines at \( \omega = -\omega_e \).
