Spin-transfer torques, both reactive and dissipative, induced by temperature gradients in conducting ferromagnets are calculated microscopically for smooth magnetization textures. Temperature gradients are treated à la Luttinger by introducing a fictitious gravitational field that couples to the energy density. The thermal torque coefficients obtained by the Kubo formula contain unphysical terms that diverge towards zero temperature. Such terms are caused by equilibrium components and should be subtracted before applying the Einstein-Luttinger relation. Only by following this procedure a familiar Mott-like formula is obtained for the dissipative spin-transfer torque. The result indicates that a fictitious field that couples to the entropy rather than energy would solve the issue from the outset.

I. INTRODUCTION

A spin current is a flow of angular momentum, which can be transferred to other degrees of freedom and thereby exerts a torque on them. In ferromagnetic conductors, an ordinary (Ohmic) electric current, induced by an applied electric field, is accompanied by a spin current, and this can be utilized to control magnetization dynamics [1,2].

Spin currents can also be induced by a temperature gradient in ferromagnets, which may be used to control magnetization without the need to apply an electric field [3–5]. For permalloy, a temperature gradient of 2 K/μm has been estimated to induce a torque equivalent to that of the electric current density of 10⁹ A/cm² necessary to move magnetic domain walls in permalloy [6,7]. Such a large temperature gradient can be realized in magnetic nanostructures by focused pulsed laser heating. Evidence for thermal torques affecting the magnetization dynamics has been obtained in spin valves [8] and magnetic tunnel junctions [9]. Domain wall motion under a temperature gradient has been observed in magnetic insulators in which spin currents are carried by magnons [10].

In this paper, we calculate spin torques induced by a temperature gradient in a conducting ferromagnet focusing on mobile conduction electrons (not magnons). We consider a general but smooth magnetization texture as described by the Landau-Lifshitz-Gilbert (LLG) equation. We follow Luttinger [11] by treating thermal perturbations in terms of a (fictitious) gravitational field that couples to the energy (or heat) density of the system and exploit the Einstein relation [12]. Thermally induced torques can then be computed by linear response theory in close analogy with the well-studied electrically induced torques, as is shown in the first half of this paper. However, a straightforward calculation leads to a physically wrong contribution which diverges towards zero temperature. The resolution of this difficulty is the main subject of this paper.

A similar problem exists in thermoelectric transport in strong magnetic fields [13–15]. In this case, the problem was resolved by separating the transport current from the magnetization current and applying the Einstein relation to the former. In calculating spin torques, we need to generalize this idea and propose to separate the nonequilibrium and equilibrium components, applying the Einstein relation to the former. The same feature exists in the ‘spin-orbit torques’ due to Rashba-type spin-orbit coupling [16,17].

This paper is organized as follows. After a brief description of spin torques in Sec. II, we define a model in Sec. III. Based on the formulation outlined in Sec. IV, we evaluate explicitly the thermal torque in Sec. V and observe that the result contains an unphysical contribution. The resolution of this problem is described in Sec. VI, and the correct result is given in Sec. VII. A consequence of our results is illustrated in Sec. VIII for thermal torques in the absence of applied electric fields. In Sec. IX, we discuss our procedure in a more general context. The results are summarized in Sec. X. Technical details of the calculations are deferred to the Appendices. Mathematical notations are summarized in the Supplemental Material [18].

II. GENERAL DESCRIPTION OF SPIN TORQUES

The LLG-Slonczewski (LLGS) equation, in which the effects of spin currents are included, reads

\[
\dot{n} = \gamma_0 H_{\text{eff}} \times n + \alpha_0 \dot{n} \times n + \ddot{t},
\]

where \( n = n(x) \) is a unit-vector field representing the spin direction of magnetization, \( x = (r,t) \) denotes the space-time coordinate, and the dot represents the time derivative. The first two terms on the right-hand side are the precessional effects of spin currents and applying the Einstein relation to the former. In calculating spin torques, we need to generalize this idea and propose to separate the nonequilibrium and equilibrium components, applying the Einstein relation to the former. The same feature exists in the ‘spin-orbit torques’ due to Rashba-type spin-orbit coupling [16,17].

For a smooth magnetization texture \( n \), the torques due to an electrically-induced spin current density \( j_s \equiv j_\uparrow - j_\downarrow = \sigma_s E \), where \( \sigma_s \) is the “spin conductivity” [see Eq. (63) below] and \( E \) is the electric field, have the form

\[
\ddot{t}_{\text{el}} = - (v_s \cdot \nabla) n - \beta n \times (v_s \cdot \nabla) n.
\]
Although the dimensionless constant term is caused by spin-relaxation processes in the conduction with the coefficient vector $m$, the spin-relaxation process is expected to produce the second term, $\beta T$ is reduced to calculating the electron spin density in the quantum statistical average. The calculation of the torque $\delta H_{sd}/\delta \mathbf{n}$ by on the magnetization since the effective field seen by $\mathbf{h}_{sd}$ is the impurity potential. In Eq. (8) the summation is carried out over normal and magnetic impurities with scattering strengths $u_i$ and $u_s$, respectively. We assume a uniform and isotropic distribution of impurity positions ($R_i$ and $R'_i$) and impurity-spin direction ($S_i$), respectively, and take a quenched average as

$$V_{\text{imp}}(\mathbf{r})V_{\text{imp}}(\mathbf{r}') = (n_i u_i^2 + \frac{1}{n_i} t_{ij}^2 S_{\text{imp}} \sigma \otimes \sigma) \delta(\mathbf{r} - \mathbf{r}') ,$$

where $n_i$ ($n_s$) is the concentration of normal (magnetic) impurities and $S_{\text{imp}}$ is the magnitude of the impurity spin. Equation (9) is a tensor in spinor space.

We consider a small transverse deviation field $\mathbf{u}$ on top of a static and uniform magnetization pointing in the $z$ direction: $\mathbf{n}(\mathbf{r}) = \hat{z} + \mathbf{u}(\mathbf{r}) \varepsilon^{\sigma \nu} \mathbf{r}$, with $\mathbf{u} \perp \hat{z}$, $|\mathbf{u}| \ll 1$. We may then focus on a single Fourier component with wave vector $\mathbf{q}$ and amplitude $a_\mathbf{q}$ and calculate the induced spin density to first order in $a_\mathbf{q}$ and $\mathbf{q}$. This is sufficient to determine the coefficients $v_s$, $\beta$, $v_T$, and $\beta T$ in Eqs. (2) and (4) [29–31]. The impurity potential $V_{\text{imp}}$ is treated in the Born approximation for the self-energy combined with ladder-type vertex corrections. The renormalized Green function (for $\mathbf{n} = 0$) is given by

$$G_{\alpha}(z) = [\mathbf{z} + \mathbf{h} - \mathbf{k}^2/2m + M \sigma + i \gamma_\alpha \text{sgn}(\text{Im} z)]^{-1} ,$$

with complex frequency $\mathbf{z}$, chemical potential $\mu$, wave vector $\mathbf{k}$, spin projection $\sigma = \pm 1$, and broadening $\gamma_\alpha$. We also define a (kinetic) Fermi energy for each spin, $\varepsilon_\mathbf{F}$.

Then the spin-dependent scattering lifetime, and $\varepsilon_\mathbf{F}$ is the density of states of spin-$\sigma$ electrons at the Fermi energy. At low enough temperatures, $\mu$ equals the Fermi energy $\varepsilon_\mathbf{F}$. We also define a (kinetic) Fermi energy for each spin, $\sigma = \pm 1$, by $\varepsilon_\mathbf{F} = \varepsilon_\mathbf{F} + M \sigma$. As in Ref. [30], we assume a good ferromagnetic metal characterized by the small $\gamma_\alpha/(\mu + \sigma M)$ and $\gamma_\alpha/M$ (collectively denoted by $\gamma$) and retain only terms to the lowest nontrivial order in $\gamma$, viz. $\mathcal{O}(\gamma^{-1})$ for the spin-transfer torque and $\mathcal{O}(\gamma^0)$ for the dissipative correction ($\beta$ term).

## IV. FORMULATION

Thermal torques induced by a temperature gradient $\nabla T$ can be calculated analogous to ordinary current-induced torques due to an electric field $E$ as outlined in the following. Let us consider the general case in which conduction electrons in a ferromagnet are subject to an applied electric field ($E$), chemical-potential gradient ($\nabla \mu$), temperature gradient ($\nabla T$), and applied gravitational field ($-\nabla \psi$). The gravitational potential $\psi$ was introduced by Luttinger [11] as a field which couples to the local energy density $h(x)$, thus driving an energy-current density $j_E$. For convenience, we prefer to work with the field that couples to $h(x) - \mu n(x)$, where $n(x)$ is the local number density, that drives the heat-current density, $j_Q = j_E - \mu j$. Then the nonequilibrium part of the transverse spin polarization, which is responsible for (nonequilibrium) spin torques, can be written as

$$\langle \delta n_{\alpha \beta}(q) \rangle = i \chi_{\alpha \beta}^0 \left( E_i + \frac{1}{e} \nabla_i \mu \right) + \chi_{\alpha \beta,ij}^0 \left( -\nabla_i T + \nabla_i \psi \right) ,$$

where $\chi_{\alpha \beta,ij}$ is the Green function of the spin polarization $n_{\alpha \beta}$, $i$ and $j$ are the local $x$ and $y$ components, $n_{\alpha \beta}$ is the anomalous spin current density, and $\chi_{\alpha \beta,ij}$ is the Green function of the spin polarization $n_{\alpha \beta}$.
where $\chi^a$ and $\chi^a_{\alpha \beta}$ are linear-response coefficients with $\alpha$ and $i$ being spin and spatial indices, respectively. [In Eq. (13), sum over $i = x, y, z$ is assumed.] We use the same coefficient for $E_i$ and $\nabla_i \mu/e$, as well as for $\nabla_i T/T$ and $\nabla_i \psi$. This can be justified by an argument \textit{à la} Einstein [11,12]: under static, finite wavelength, and longitudinal perturbation, the system is in an equilibrium state, implying that nonequilibrium torques should not arise.

Thus we consider the Hamiltonian

$$H_{b,\phi} = \int d^3 x \{ h(x) - (\mu + e \phi(x)) n(x) \} (1 + \psi(x)), \quad \text{(14)}$$

where $\phi$ is the electromagnetic scalar potential, $\psi$ is the gravitational potential, and $h(x)$ is given by Eq. (7). The linear-response coefficients, $\chi^a$ and $\chi^a_{\alpha \beta}$, to the mechanical perturbations, $E_i = -\nabla_i \phi$ and $-\nabla_i \psi$, are given by the standard Kubo formula [11,32]

$$\chi^a = \lim_{\omega \to 0} \frac{K^a_i(q, \omega + i 0) - K^a_i(q, 0)}{i \omega}, \quad \text{(15)}$$

$$\chi^a_{\alpha \beta} = \lim_{\omega \to 0} \frac{K^a_{\alpha \beta}(q, \omega + i 0) - K^a_{\alpha \beta}(q, 0)}{i \omega}, \quad \text{(16)}$$

where the response functions for real frequencies $\omega$ are obtained from those defined in the imaginary time $\tau = it$ or the corresponding Matsubara frequencies $\omega_n = \pi \tau k_B T_0$ ($\lambda$: integer) by analytic continuation $i \omega_n \to \omega + i 0$ in the complex plane [33],

$$K^a_i(q, i \omega_n) = -e \int_0^{\beta} d \tau \langle T_\tau \delta^a(q, \tau) J_i \rangle, \quad \text{(17)}$$

$$K^a_{\alpha \beta}(q, i \omega_n) = \int_0^{\beta} d \tau \langle T_\tau \delta^a_{\alpha \beta}(q, \tau) J_{\alpha \beta} \rangle, \quad \text{(18)}$$

cf. Appendix A. The linear-response coefficients are computed for a uniform background temperature $T_0$ and $\beta_0 = (k_B T_0)^{-1}$ that is perturbed by a small $\nabla T$. For simplicity, we use the notation $T_0$ only here but use $T$ instead of $T_0$ in the remaining sections including the Appendices. On the other hand, we keep the notation $\beta_0$ throughout the paper in order to distinguish it from the $\beta$ term in the LLGS equation. In Eqs. (17) and (18), $J$ is the total charge current (in units of $-e$) and $J_Q$ is the total heat current; they are given by the volume integral of the corresponding current densities (see Appendix B):

$$j(x) = \frac{h}{2m_i} \lim_{x' \to x} (V'(x) - V(x')) \xi(x') c^c(x'), \quad \text{(19)}$$

$$j_Q(x) = \frac{ih}{4m} \lim_{x' \to x} (V'(x) - V(x')) \langle \partial_{x'} - \partial_{x'} \rangle c^c(x') \xi(x') \quad - \frac{ih^2}{4m} \nabla x_{\alpha} [c^c(x') c^c(x)], \quad \text{(20)}$$

where $x = (r, \tau)$ and $x' = (r', \tau')$. Note that the expression (20) is written in the imaginary-time representation [33]. Note also that the last term in Eq. (20) drops out for the total heat current $J_Q$.

The response functions, $K^a_i$ and $K^a_{\alpha \beta,i}$, are nonzero in the presence of magnetization textures, Eq. (10), and we extract $u^a_i$ and $q_i$ from $K^a_i$ and $K^a_{\alpha \beta,i}$. In the next section, we derive the forms [34]

$$K^a_i(q, i \omega_n) = -e M^{-1} (\tilde{b} \delta^a_{\beta \beta} + \tilde{a} \delta^a_{\alpha \beta}) \omega q_i u^a_q, \quad \text{(21)}$$

$$K^a_{\alpha \beta}(q, i \omega_n) = M^{-1} (\tilde{b} \delta^a_{\beta \beta} + \tilde{a} \delta^a_{\alpha \beta}) \omega q_i u^a_q, \quad \text{(22)}$$

where $\delta^a_{\alpha \beta}$ is the Kronecker’s delta and $\epsilon^{a \beta \gamma}$ is the antisymmetric tensor (with $\epsilon^{xy} = 1$) in two dimensions, while $\tilde{a}, \tilde{b}, \tilde{a}_T,$ and $\tilde{b}_T$ are yet unspecified coefficients. These expressions indeed lead to the torques given by Eqs. (2) and (4), with

$$v_s = -\frac{\tilde{a}}{s_{\text{ext}}} (e E + \nabla \mu), \quad \beta = \tilde{b}/a, \quad \text{(23)}$$

$$v_T = -\frac{\tilde{a}_T}{s_{\text{ext}}} (\nabla T + \nabla \psi), \quad \beta_T = \tilde{b}_T/a. \quad \text{(24)}$$

The calculation of the coefficients $\tilde{a}, \tilde{b}, \tilde{a}_T,$ and $\tilde{b}_T$ in Eqs. (21) and (22) is the subject of the next two sections.

Before proceeding, we show that the two cases (electrical and thermal) can actually be calculated simultaneously. In Eqs. (17) and (18), the (imaginary-)time evolution and thermal average are determined by $H$. Since this is a one-body Hamiltonian, $\hat{\epsilon} = [c, H]/i\hbar$ is also a one-body operator. We therefore can use Wick’s theorem to obtain

$$K^a_i(q, i \omega_n) = e T_0 \sum_{n, k} v_k,i \text{tr}[\sigma^a G_{k+q+k}^+(\omega) G_{k+k}], \quad \text{(25)}$$

$$K^a_{\alpha \beta}(q, i \omega_n) = -e T_0 \sum_{n, k} (i \epsilon_n + i \omega_n) \sum_{k, k'} v_{k,i} \text{tr}[\sigma^a G_{k+q+k}^+(\omega) G_{k+k'}], \quad \text{(26)}$$

Here, $\epsilon_n = (2n + 1)\pi k_B T_0$, $G_{k+q+k'}(\omega_n) \equiv G_{k+q+k'}(\epsilon_n) \equiv -\int_0^{\beta} d \tau e^{-i \omega_n \tau} \langle T_\tau c_{k+q+k'}(\tau) c_{k+q+k'} \rangle$ is the exact Green function of $H$ (before the impurity average is taken), $G^+$ is the one with frequency $i \epsilon_n + i \omega_n, v_k,i = h/k \hbar/m$ is the electron velocity, and “$\tau$” means trace in spin space. (Since $H$ includes $u(r)$ and $V_{\text{imp}}$, $G$ has off-diagonal components in both spin and wave vector.) In deriving Eq. (26), we used the relation

$$\langle T_r c_{\alpha}(c^{\dagger}) \rangle = -\langle T_r \hat{c}_{\alpha}(c^{\dagger}) \rangle = \frac{d}{d\tau} G(\tau) + \delta(\tau). \quad \text{(27)}$$

The last term of Eq. (26) is invariant with respect to the translation $\epsilon_n + \omega_n \to \epsilon_n$ and after summing over $\epsilon_n$ does not depend on $\omega_n$. Such terms not depending on $\omega$ (hence $\omega_n$) cancel in Eq. (16), and can be dropped beforehand. Thus we are left only with the first term of Eq. (26), showing that the heat-current vertex is simply governed by the factor $(i \epsilon_n + i \omega_n)/2 v_k$. We confirmed this statement starting from an explicit expression for the heat current (without using the time derivative) in Appendix C. (For many-body Hamiltonians, see Ref. [35].)

V. EXPLICIT CALCULATION

We calculate the torque coefficients, $K^{a\beta}_{ij}$ and $K^{a\beta}_{Q,ij}$ [Eqs. (21) and (22)] by first extracting $q_j$ and $u^a_q$ from $K^a_i$...
and $K^a_{Q,i}$ as

$$K^a_{Q,i}(q,i\omega_n) = -eM K^{a\beta}_{ij}(i\omega_n) q_j u^\beta,$$

(28)

where summing over $j = x,y,z$ and $\beta = x,y$ is implied. Up to the second-leading order in $\gamma$, they are expressed diagrammatically in Fig. 1. These “four-point” diagrams are obtained from the “two-point bubble diagrams” that express the correlation functions of spin and current, Eqs. (17) and (18) or Eqs. (25) and (26), by extracting $u^\beta$ and $q_j$. They read

$$K^{a\beta}_{ij}(i\omega_n) = T \sum_n \phi^{a\beta}_{ij}(i\epsilon_n + i\omega_n,i\epsilon_n),$$

(30)

$$K^{a\beta}_{Q,ij}(i\omega_n) = T \sum_n (i\epsilon_n + i\omega_n/2) \phi^{a\beta}_{ij}(i\epsilon_n + i\omega_n,i\epsilon_n),$$

(31)

where [36]

$$\phi^{a\beta}_{ij}(i\epsilon_n + i\omega_n,i\epsilon_n) = \sum_k v_i v_j [\sigma^a G^+ G^+ \sigma^\beta G^+ G] - [\sigma^a G^+ G^+ G^+ G]$$

$$+ \Gamma_0 \sum_{k,k'} v_i v_j [\sigma^a G^+ G^+ G^+ G]$$

$$- [\sigma^a G^+ G^+ G^+ G]$$

$$+ \Gamma_0 \sum_{k,k'} v_i v_j [\sigma^a G^+ G^+ G^+ G]$$

$$- [\sigma^a G^+ G^+ G^+ G].$$

(32)

After the analytic continuation, $i\omega_n \rightarrow \hbar \omega + i0$, we expand $K^{a\beta}_{ij}$ and $K^{a\beta}_{Q,ij}$ with respect to $\omega$ as

$$K(\omega + i0) - K(0)$$

$$= i\hbar \omega \frac{2\pi}{\epsilon} \int_{-\infty}^{\infty} d\epsilon \left( -\frac{\partial f}{\partial \epsilon} \right) [\text{Re}[\psi^{(1)}(\epsilon,\epsilon)] - \psi^{(2)}(\epsilon,\epsilon)]$$

$$- \frac{\hbar \omega}{2\pi} \int_{-\infty}^{\infty} d\epsilon f(\epsilon) (\partial_\epsilon - \partial_\epsilon') \text{Im}[\psi^{(1)}(\epsilon,\epsilon')]|_{\epsilon' = \epsilon} + \mathcal{O}(\omega^2),$$

(33)

where $f(\epsilon)$ is the Fermi-Dirac distribution function, and $\partial_\epsilon = \partial/\partial \epsilon$, $\partial_\epsilon' = \partial/\partial \epsilon'$. In Eq. (33), $\varphi^{a\beta}_{ij}(\epsilon,\epsilon')$ for $K = K^{a\beta}_{ij}$, and $\varphi^{a\beta}_{ij}(\epsilon,\epsilon')$ for $K = K^{a\beta}_{Q,ij}$; the superscripts on $\varphi^{a\beta}$ specify the analytic continuations, $\varphi^{(1)}(\epsilon,\epsilon') = \varphi(\epsilon + i0,\epsilon' + i0)$, $\varphi^{(2)}(\epsilon,\epsilon') = \varphi(\epsilon + i0,\epsilon' - i0)$, and $\varphi^{(3)}(\epsilon,\epsilon') = \varphi(\epsilon - i0,\epsilon' - i0)$.

After some manipulations, the coefficients can be cast into the form,

$$\tilde{a} = \int_{-\infty}^{\infty} d\epsilon \left( -\frac{\partial f}{\partial \epsilon} \right) A(\epsilon),$$

(34)

$$\tilde{b} = \int_{-\infty}^{\infty} d\epsilon \left( -\frac{\partial f}{\partial \epsilon} \right) B(\epsilon) - \int_{-\infty}^{\infty} d\epsilon f(\epsilon) \partial_\epsilon C(\epsilon),$$

(35)

for electrically-induced torques, and

$$\tilde{a}_T = \int_{-\infty}^{\infty} d\epsilon \left( -\frac{\partial f}{\partial \epsilon} \right) \epsilon A(\epsilon),$$

(36)

$$\tilde{b}_T = \int_{-\infty}^{\infty} d\epsilon \left( -\frac{\partial f}{\partial \epsilon} \right) \epsilon B(\epsilon) - \int_{-\infty}^{\infty} d\epsilon f(\epsilon) \epsilon \partial_\epsilon C(\epsilon),$$

(37)

for thermally induced torques. The terms containing $-\partial f/\partial \epsilon$ are called “Fermi-surface terms,” and those with $f(\epsilon)$ as “Fermi-sea terms” [37]. This separation is not unique in a strict sense, but convenient in practice (at least in the present context) if defined symmetrically ($\epsilon \pm \omega/2$) as in Eq. (33). The functions $A,B$, and $C$ are given by

$$A(\epsilon) = \frac{M^2}{\pi} \sum_\sigma \text{Re} L_{\sigma}(\epsilon),$$

(38)

$$B(\epsilon) = \frac{M^2}{\pi} \sum_\sigma \text{Im} L_{\sigma}(\epsilon),$$

(39)

$$C(\epsilon) = \frac{M^2}{\pi} \sum_\Lambda \text{Im} \sum_{k,k'} v_i v_j \left( G^R_{k\sigma} G^R_{k'\sigma} \right)^2,$$

(40)

with $G^R_{k\sigma} = G^R_{k\sigma}(\epsilon) \equiv G_{k\sigma}(\epsilon + i0)$ and $G_{k\sigma}(\epsilon) \equiv G_{k\sigma}(\epsilon - i0)$ being retarded (R) and advanced (A) Green functions, respectively, and

$$L_{\sigma}(\epsilon) = \sum_k v_i v_j G^R_{k\sigma} G^R_{k\sigma} G^A_{k'\sigma} \left[ 1 + \Gamma_0 \sum_{k'} G^R_{k'\sigma} G^R_{k'\sigma} G^A_{k'\sigma} \right].$$

(41)
In Eqs. (40) and (41), all Green functions share the frequency argument $\epsilon$. Equations (34)–(37) can be rewritten as

\[
\tilde{a} = A_0, \quad \tilde{b} = B_0 - C_0, \quad \tilde{a}_T = A_1, \quad \tilde{b}_T = B_1 - C_1 + c,
\]

where

\[
A_n = \int_{-\infty}^{\infty} d\epsilon \left(-\frac{\partial f}{\partial \epsilon}\right)e^\sigma A(\epsilon),
\]

and similarly for $B_n$ and $C_n$, with

\[
c = \int_{-\infty}^{\infty} d\epsilon f(\epsilon) C(\epsilon).
\]

Using Eq. (6), the torques are obtained as

\[
t_{\text{el}} = \left[A_0 \partial_i n + (B_0 - C_0)(n \times \partial_i n)\right]eE_i,
\]

\[
t^{(\psi)} = \left[A_1 \partial_i n + (B_1 - C_1 + c)(n \times \partial_i n)\right]j_\psi.
\]

Note that as $T \to 0$, $A_1$, $B_1$, and $C_1$ vanish, but $c$ remains finite. The $c$ term in Eq. (47),

\[
\Delta t^{(\psi)} = c(n \times \partial_i n) j_\psi,
\]

is problematic because the Einstein-Luttinger relation (13) leads to a thermally induced torque

\[
\Delta t_{\text{th}} = c(n \times \partial_i n) j_{\psi T}/T,
\]

that diverges as $T \to 0$ (since $c$ is finite as $T \to 0$). This contradicts the thermodynamic law (Nernst theorem) that thermally induced effects should vanish with temperature. Also, the predicted finite $\beta_T$ even in the absence of spin relaxation violates the spin conservation. Therefore, the contribution (48) must be carefully reconsidered.

VI. SUBTRACTION OF EQUILIBRIUM COMPONENTS

To settle the problem encountered in the last section, we note that the combination $-\nabla \psi - \nabla T/T$ in Eq. (13) should be applied only to nonequilibrium components that must be identified beforehand. Even at equilibrium, i.e., without external fields $E_i = 0$ and $\psi = 0$, a finite spin density $\langle \sigma \rangle_{\text{eq}} = (c/M) \nabla^2 n$ exists, which corresponds to the exchange-stiffness torque

\[
t_{\text{eq}} = c(n \times \nabla^2 n).
\]

The coefficient $c$ is the same as in Eq. (45), and represents the contribution of the conduction electrons to the exchange-stiffness constant; see Appendix D for the calculation.

This equilibrium torque is affected by $\psi$ in two ways. First, the torque formula, Eq. (6), acquires an additional factor

\[
t^{(\psi)}_{\text{sd}} = Mn(x) \times \langle \delta(x) \rangle (1 + \psi)
\]

because the $s$-$d$ coupling $h_{sd}$ [Eq. (5)] is multiplied by $(1 + \psi)$ [see Eq. (14)] and so are the effective field, $-\partial H_{sd}/\partial n$, and the $s$-$d$ exchange torque, $-\langle \delta H_{sd}/\partial n \rangle n$ [cf. Eq. (6)] [28]. Secondly, it seems that the spin density $\langle \delta \rangle$ may be modified by $\psi$ (on top of a term proportional to $\partial_\psi \psi$). It turns out, however, that this is not the case; see Eq. (E8) for an explicit expression and Appendix A for a formal derivation. From a general point of view, this reflects the adiabatic nature of the Kubo formula and the conserved nature of the perturbed quantity (energy), as shown in Appendix F. Therefore, the equilibrium spin density $\langle \delta \rangle_{\text{eq}}$ in the previous paragraph (for $\psi = 0$) is not affected by a uniform $\psi$ (namely, in the zeroth-order gradient of $\psi$). Therefore, using Eq. (50) in Eq. (51), we obtain

\[
t^{(\psi)}_{\text{eq}} = c(n \times \nabla^2 n)(1 + \psi),
\]

(The suffix $\text{eq}$ means that this does not exhaust the equilibrium torque in the presence of $\psi$.) The total torque is the sum of Eq. (52) and Eq. (47); the former contains all torques proportional to $\psi$, and the latter those proportional to $\partial_\psi \psi$. Focussing on terms containing $c$

\[
t^{(\psi)}_{\text{eq}} + \Delta t^{(\psi)} = -\partial_\psi j^{(\psi)}_{\text{sd}},
\]

where

\[
j^{(\psi)}_{\text{sd}} = -c(n \times \partial_i n)(1 + \psi)
\]

is the spin-current density carried by the $n$ field in the presence of $\psi$. The right-hand side of Eq. (53) represents the (generalized) exchange-stiffness torque in the presence of $\psi$, which we identify as the total equilibrium torque. By subtracting this equilibrium component, we identify the nonequilibrium component to be Eq. (47) without the offensive $c$ term. The replacement, $\partial_\psi \psi \to \partial_\psi \psi T/T$, should be enforced only in this nonequilibrium component such that

\[
t_{\text{th}} = [A_1 \partial_i n + (B_1 - C_1)(n \times \partial_i n)] \partial_\psi T/ T,
\]

behaves regularly (namely, vanishes) as $T \to 0$.

The above procedure, Eqs. (52)–(55), may be better understood by subjecting an insulating ferromagnet (without mobile $s$ electrons) to $\psi$. Its Lagrangian is given by

\[
L = \int d^3x \left\{ hS\dot{\psi} \cos \theta - \frac{J}{2} (\nabla n)^2 (1 + \psi) \right\},
\]

where $(\theta, \phi)$ represents the direction of $n$. Note that $\psi$ couples only to the energy density $J(\nabla n)^2/2$ (anisotropy, damping, etc. are neglected for simplicity), and not to the kinetic term (first term). The variational principle leads to the equation of motion [28]

\[
hS \dot{n} = J \partial_\psi [n \times \partial_i n (1 + \psi)],
\]

whose right-hand side precisely corresponds to Eq. (53). This supports the identification of the equilibrium torque in the preceding paragraph. The subtraction procedure becomes necessary because the equilibrium component $J(n \times \partial_i n)(\partial_\psi \psi)$ contained in Eq. (57) creeps into the Kubo-formula result.

This kind of difficulty has been noted for thermal transport in magnetic fields. To resolve it, the authors of Refs. [13–15] proposed to extract the transport current by subtracting the magnetization current, and then to apply the substitution $\partial_\psi \psi \to \partial_\psi \psi T/T$ to the transport current. In this procedure, it is essential that the expressions for electric and heat currents are modified by $\psi$ [as in Eq. (51)]. As we have seen in this section, precisely the same features exist in the calculation of (ordinary) spin torques.
VII. RESULT

We thus arrive at expressions for the nonequilibrium torque

\[ \mathbf{t}_{\text{tot}} = \mathbf{t}_e + \mathbf{t}_h, \]

\[ \mathbf{t}_e = [A_0 \nabla \mathbf{n} + (B_0 - C_0)(\mathbf{n} \times \nabla \mathbf{n})] \mathbf{J}_e, \]

\[ \mathbf{t}_h = [A_1 \nabla \mathbf{n} + (B_1 - C_1)(\mathbf{n} \times \nabla \mathbf{n})] \frac{\mathbf{J}_h}{T}, \]

where the coefficients are given by (44) with [30]

\[ A(\varepsilon) = \frac{\hbar}{2e} \sigma_s(\varepsilon), \quad B(\varepsilon) - C(\varepsilon) = \frac{\hbar}{2e} \beta(\varepsilon) \sigma_s(\varepsilon), \]

and thus

\[ \mathbf{t}_e = \frac{\hbar}{2e} \mathbf{E}_i \int d\varepsilon \left( -\frac{\partial F}{\partial \varepsilon} \right) \sigma_s(\varepsilon) \nabla \mathbf{n} + \mathbf{v}_n \times \mathbf{J}_e \right|_{\mathbf{E} = 0}, \]

\[ \mathbf{t}_h = \frac{\hbar}{2e} \mathbf{E}_i \int d\varepsilon \left( -\frac{\partial F}{\partial \varepsilon} \right) \beta \sigma_s(\varepsilon) \nabla \mathbf{n} + \mathbf{v}_n \times \mathbf{J}_e \right|_{\mathbf{E} = 0}, \]

where the electric field \( \mathbf{E} \) in \( \mathbf{t}_h \) is replaced by the temperature gradient \( \nabla T \) in \( \mathbf{t}_e \). \( \mathbf{t}_e(\varepsilon) \) is defined by the total integrand of Eq. (61) including the prefactor.

For sufficiently low temperatures, the Sommerfeld expansion

\[ \int_{-\infty}^{\infty} d\varepsilon F(\varepsilon) \left( \frac{\partial F}{\partial \varepsilon} \right) = F(0) + \frac{\pi^2}{6} F''(0)(k_B T)^2 + \cdots \]

can be used to evaluate as \( A_0 = 0, \quad A_1 = -\frac{\pi^2}{3} A'(0) (k_B T)^2 \), etc. Here, the prime originally refers to the \( \varepsilon \) derivative, but it can be redefined to be the \( \varepsilon_F \) derivative, since \( \varepsilon \) and \( \varepsilon_F \) appear only as \( \varepsilon + \varepsilon_F \) in the unperturbed Green function, Eq. (11), and the factor \( \varepsilon \) in Eqs. (36) and (37) does not appear in \( F''(0) \). Hence

\[ \tilde{a}_T = \frac{\pi^2}{3} \frac{d\tilde{a}}{d\varepsilon_T} (k_B T)^2, \quad \tilde{b}_T = \frac{\pi^2}{3} \frac{d\tilde{b}}{d\varepsilon_T} (k_B T)^2, \]

or

\[ \tilde{t}_h = \frac{\pi^2}{3} (k_B T)^2 \tilde{a} \int_{E - \nabla T}^{E_T} \tau(e) \right|_{e \rightarrow -\nabla T}. \]

These are ‘Mott formulas’ for the thermally induced spin-transfer torques in terms of the \( \varepsilon_F \) derivative of the electrical counterpart.

Explicitly, the total torque is written as

\[ \mathbf{t}_{\text{tot}} = \frac{\hbar}{2eS_{\text{tot}}} \left\{ \left( j_s^{\text{tot}} \cdot \nabla \right) \mathbf{n} + \beta \mathbf{n} \times \left( j_s^{\text{tot}} \cdot \nabla \right) \mathbf{n} \right\} + \beta' \mathbf{n} \times \left( j_{Q,s} \cdot \nabla \right) \mathbf{n}, \]

where

\[ j_s^{\text{tot}} = \sigma_s(E + S_s \nabla T), \quad S_s = \frac{\pi^2 k_B^2}{3e} \frac{\sigma_s'}{\sigma_s} T, \]

with \( S_s \) reflecting the spin dependence of the Seebeck coefficient, and

\[ j_{Q,s} = \frac{\pi^2 k_B^2}{3e} \sigma_s T \nabla T \]

is the ‘spin-heat’ current density, i.e., spin-polarized part of the heat-current density (multiplied by \( -\varepsilon \)). The second and the third terms in the brackets of Eq. (69) follow from \( (\beta \sigma_s') = \beta \sigma_s' + \beta \sigma_s \). While the first and the second terms are the ordinary spin-transfer torque and the \( \beta \) term due to thermoelastic spin current, the third term (with \( \beta' \)) is the spin torque directly driven by the heat current.

Although the present calculation is based on a specific model (as to the band structure and the spin-relaxation process), the principal result, Eq. (65), relating the thermal torques to the electrical ones, will hold quite generally. The same relation has also been derived for the so-called ‘spin-orbit torque’ [16,17].

Hals et al. [25] derived \( \beta_T \) by scattering theory and evaluated it numerically for finite-length wires of magnetic semiconductors. They did not encounter unphysical divergences because their formalism focuses on the dissipation into contacts to the magnet, which automatically excludes any equilibrium components.

VIII. APPLICATIONS

To illustrate the implications of the microscopic result, we consider now a temperature gradient without external electric field, \( \mathbf{E}_{\text{ext}} = 0 \). The spin torque depends on the type of the circuit (closed or open) because of the internal field \( \mathbf{E}_{\text{int}} \), where \( \mathbf{E} = \mathbf{E}_{\text{ext}} + \mathbf{E}_{\text{int}} \). The total spin torque (69) may then be rewritten as

\[ \mathbf{t}_{\text{tot}}(\mathbf{E}_{\text{ext}} = 0) = \frac{\hbar}{2eS_{\text{tot}}} \left( 1 + \beta_{\text{eff}} \mathbf{n} \times \mathbf{v}_n \right) \left( j_s^{\text{tot}} \cdot \nabla \right) \mathbf{n}. \]

where \( j_s^{\text{tot}} \) is proportional to \( \nabla T \) and \( \beta_{\text{eff}} \) is an effective beta parameter. For a closed circuit, \( \mathbf{E} = 0 \), the thermal spin-transfer torque is governed by the thermoelastic spin current \( j_s^{\text{closed}} \), the thermal \( \beta \) term by

\[ \beta_{\text{closed}} = \frac{\pi^2 k_B^2}{3e} \beta \sigma_s' \left( \frac{\sigma_s'}{\sigma_s} + \frac{\beta}{\beta'} \right) T \nabla T, \]

or

\[ \beta_{\text{closed}} = \beta + \frac{\beta' \sigma_s}{\sigma_s'}. \]

For open circuits \( j_s^{\text{open}} = \sigma_s(E + S_s \nabla T) = 0 \) with \( \sigma_s = (e^2/m)(\nu_1 \tau_1 + \nu_2 \tau_2) \) and \( S_s = (\pi^2 k_B^2/3e) \sigma_s / \sigma_s T \), the thermal spin-transfer torque is governed by \( j_s^{\text{open}} = \sigma_s(S_s - S_s) \nabla T \).
The thermal $\beta$ term then reads
\begin{equation}
\beta_T^{\text{open}} f_s^{\text{open}} = \frac{\pi^2 k_B^2}{3e} \beta T \sigma_s \left( -\frac{\sigma'_s}{\sigma_c} + \frac{\sigma'_c + \beta'}{\beta} \right) \mathcal{N}_T, \tag{75}
\end{equation}
where
\begin{equation}
\beta_T^{\text{open}} = \beta + \beta' \left( \frac{\sigma'_s}{\sigma_s} - \frac{\sigma'_c}{\sigma_c} \right)^{-1}. \tag{76}
\end{equation}
Thus, the thermal $\beta_T$ differs from the electrical one ($\beta$) when $\beta' \neq 0$.

In the present model (7) with parabolic electron dispersion and high electron densities, $\sigma_c$ depends on $E_F$ only weakly [39] and the thermoelectric spin current ($\propto \sigma'_s$) is vanishingly small, whereas $\sigma'_s/\sigma_c \approx 1/E_F$ and $\beta'/\beta = (v'_s + v'_c)/(v_s + v_c) \approx 1/2E_F$ if $E_F \pm M$ are not too small compared to $E_F$.

Therefore, in closed circuits, the thermal spin-transfer torque is dominated by the thermal $\beta$ term $\propto \beta' \sigma_c T \mathcal{N}_T$ driven by the spin-heat current, Eq. (71). By opening the circuits, both torques change sign by the effect of $E_s$ ($\propto -\sigma'_s/\sigma_c$).

A domain wall can therefore be driven into opposite directions in closed and open circuits. In real materials, such features of course depend on the details of spin-relaxation mechanism and band structure, but the driving by spin-heat currents dominates when the energy dependence (at the Fermi level) of the spin conductivity is weak (such that thermoelectric spin currents are suppressed) while that of $\beta$ is strong.

**IX. GENERAL ASPECTS**

In this section, we draw some general conclusion out of the analysis in the previous sections. For this purpose, it is convenient to shift the (off-shell) energy variable $E$ as $E \rightarrow \mu - \mu$, so that the Fermi-Dirac distribution function is explicitly $\mu$ dependent but the Green functions are not. Without introducing new functions, we redefine $f(E) = (e^{\beta(\mu-E)} + 1)^{-1}$ instead of $f(E) = (e^{\beta E} + 1)^{-1}$, and $G(E) = (e - \varepsilon_k + \cdots)^{-1}$ instead of $G(E) = (e + \mu - \varepsilon_k + \cdots)^{-1}$, and similarly for $B(e)$ and $C(e)$. (We focus on $\mathcal{N}$ and $\beta_T$.)

Following Luttinger’s prescription, we considered the linear response to a field $\Psi$ which couples to the energy (or heat) density. Thermal response functions have been obtained from the electrical response functions by simply introducing an $(e - \mu)$ factor inside the $E$ integral. This “$(e - \mu)$-factor prescription” works well for the Fermi-surface term,
\begin{equation}
\chi_{\text{el}}^{\text{surface}} = \int_{-\infty}^{\infty} dE \left( -\frac{\partial f}{\partial E} \right) B(E), \tag{77}
\end{equation}
\begin{equation}
\chi_{\text{th}}^{\text{surface}} = \int_{-\infty}^{\infty} dE \left( -\frac{\partial f}{\partial E} \right) (e - \mu) B(E). \tag{78}
\end{equation}

On the other hand, for the Fermi-sea terms, it leads to an unphysical contribution that can be repaired by subtracting the equilibrium components, leading to
\begin{equation}
\chi_{\text{el}}^{\text{sea}} = \int_{-\infty}^{\infty} dE f(E) D(E), \tag{79}
\end{equation}
\begin{equation}
\chi_{\text{th}}^{\text{sea}} = \int_{-\infty}^{\infty} dE f(E) (e - \mu) D(E) - \int_{-\infty}^{\infty} dE f(E) C(E). \tag{80}
\end{equation}
where $D(E) \equiv -\partial E / \partial C(E)$. The first term in $\chi_{\text{th}}^{\text{sea}}$ includes the $(e - \mu)$ factor for the heat (or heat-current) vertex, while the second term subtracts the equilibrium component. By integration by parts,
\begin{equation}
\chi_{\text{th}}^{\text{sea}} = \int_{-\infty}^{\infty} dE \left[ (e - \mu) f(E) - \Omega(E) \right] D(E), \tag{81}
\end{equation}
where
\begin{equation}
\Omega(E) = -\frac{E}{\mu} \int_{-\infty}^{\infty} dE f(E) = -T \ln(1 + e^{\beta(\mu-E)}), \tag{82}
\end{equation}
assuming that $\varepsilon C(e) \rightarrow 0$ as $\varepsilon \rightarrow -\infty$. We note that $\Omega(E)$ is nothing but the grand-canonical free energy for fermions at energy $\varepsilon$ [40]. Since the first term in the brackets of Eq. (81) represents the (average) energy, $E(\varepsilon) = \varepsilon f(\varepsilon)$, the terms in the brackets can be regarded as $E(\varepsilon) - \mu f(\varepsilon) = \Omega(E) - F(\varepsilon) = TS(\varepsilon)$, where $F(\varepsilon) = \Omega(E) + \mu f(\varepsilon)$ is the corresponding Helmholtz free energy, and
\begin{equation}
S(\varepsilon) = \frac{E}{\mu} \int_{-\infty}^{\infty} dE f(E) + \ln(1 + e^{\beta(\mu-E)}) \tag{83}
\end{equation}
is the entropy. Thus we obtain the suggestive expression,
\begin{equation}
\chi_{\text{th}}^{\text{sea}} = T \int_{-\infty}^{\infty} dE S(\varepsilon) D(E). \tag{84}
\end{equation}

Since the entropy behaves regularly and vanishes in the limit $T \rightarrow 0$, so does $\chi_{\text{th}}^{\text{sea}}/T$ [41]. The unphysical divergence has thus been removed.

If we define
\begin{equation}
\Phi(T, \mu) = \int_{-\infty}^{\infty} dE \Omega(E) D(E), \tag{85}
\end{equation}
and note the relations, $f(E) = -\partial \Omega(E)/\partial \mu$ and $S(E) = -\partial \Omega(E)/\partial T$,
\begin{equation}
\chi_{\text{el}}^{\text{sea}} = -\frac{\partial}{\partial \mu} \Phi(T, \mu), \tag{86}
\end{equation}
\begin{equation}
\chi_{\text{th}}^{\text{sea}} = -T \frac{\partial}{\partial T} \Phi(T, \mu). \tag{87}
\end{equation}
which look very much like thermodynamic formulas. Similar expressions are possible for the Fermi-surface terms as well [42]. A formula similar to Eq. (86) has been derived by Stˇreda for the Fermi-sea term of the Hall conductivity [43].

The above considerations suggest the following prescription for the calculation of thermal response functions. Given the electrical response functions, Eqs. (77) and (79), the thermal response functions, Eqs. (78) and (84), are obtained by the replacement,
\begin{equation}
f(E) \rightarrow TS(E). \tag{88}
\end{equation}
This prescription works for the Fermi-surface term as well, since $(-\partial f/\partial \varepsilon)$ is replaced by
\begin{equation}
T \left( -\frac{\partial S}{\partial \varepsilon} \right) = (e - \mu) \left( -\frac{\partial f}{\partial E} \right), \tag{89}
\end{equation}
which is identical with the $(e - \mu)$-factor prescription for the Fermi-surface term, leading to Eq. (78). Although we did not derive this procedure from first principles, it suggests that a (fictitious) field that couples to the entropy density (times temperature), rather than to the energy (or heat) density, has more direct relevance for the problem.
X. SUMMARY

We presented a microscopic model calculation of spin torques induced by a temperature gradient in a conducting ferromagnet. Based on the observation that Luttinger’s prescription leads to an unphysical result, we recognized that the Einstein relation should be applied only to the nonequilibrium contributions; the equilibrium component from the Kubo formula should therefore be removed before applying the Einstein relation.

In the subtraction procedure, we noted (i) the modification of the torque formula by \( \psi [\text{Eq. (51)}] \), but (ii) the absence of a linear response to \( \psi \) (not \( \nabla \psi \)); the latter reflects the adiabatic nature of the Kubo formula and the conservation of energy (to which the field \( \psi \) couples). We note that a field that couples to the entropy density appears to directly lead to the desired results, but a formal proof is still necessary.

A general thermoelectric relation between thermal and electrical torques \( \text{Eq. (65)} \) leads to a generalized Mott formula \( \text{Eq. (68)} \) for sufficiently low temperatures. When the dissipative correction (\( \beta \) term) depends on energy, an additional \( \beta_T \) term beyond the simple thermoelectric effect (due to spin currents induced by temperature gradients) arises that can be important when the energy dependence of the spin conductivity is weak and/or that of the density of states is strong.

Note added. Recently, a paper appeared [44] in which thermal transport phenomena are studied by introducing a thermal vector potential. The terms which lead to the unphysical divergence at zero temperature presumably automatically cancel by the diamagnetic current associated with this thermal vector potential. However, at the end of the day Tatara calculates an equivalent of our Eqs. (A5)–(A8), and both his and our treatment (before the subtraction procedure) should give the same results. Tatara demonstrates that the weak-field thermal Hall effect vanishes for zero temperature, but only to leading order in the electron scattering rate. However, this does not resolve the divergence we address here, which originates from the higher-order scattering terms. The thermal vector potential is therefore not a substitute for the subtraction technique proposed here. Tatara mentions in passing that the thermal spin torque is well behaved at zero temperature. However, this is because the divergence has already been removed in the starting expression of his Ref. [20] rather than by the thermal vector potential.

ACKNOWLEDGMENTS

HK would like to thank Erik van der Bijl for valuable discussion in the final stage of the present work. We also thank Gen Tatara for candid discussions. This work was supported by Grants-in-Aid for Scientific Research (Nos. 21540336, 25400339, and 25247056) from the Japan Society for the Promotion of Science (JSPS).

APPENDIX A: LINEAR RESPONSE TO GRAVITATIONAL FIELD

Here we summarize some formulas of the linear response to a "gravitational potential" \( \psi \), which couples to the energy density of the system, as considered by Luttinger [11]. To be specific, let us take \( \psi(r,t) = \psi_q e^{(q \cdot r - \omega t)} \). Then the perturbation is described by

\[
H' = \psi_q h(-q)e^{-i\omega t}, \tag{A1}
\]

where \( h(q) \) is the Fourier component of the energy density \( h(x) \). (In this paper, \( h \) actually means \( h - \mu n \), as stated just above Eq. (13).) To first order in \( \psi \), the response of a physical quantity \( \hat{A} \) is expressed as

\[
\langle \hat{A} \rangle _\psi = -K_0(q, \omega + i0) \psi_q e^{-i\omega t}. \tag{A2}
\]

The response function \( K_0(q, \omega + i0) \) is obtained from

\[
K_0(q, i\omega_\lambda) = \int_0^{\beta T} d\tau e^{i\omega_\lambda \tau} \langle \hat{\tau} \hat{A}(\tau) h(-q) \rangle \tag{A3}
\]

by analytic continuation, \( i\omega_\lambda \to i\omega + i0 \). Let us introduce the heat-current operator \( J_Q \) by the continuity equation for the energy (measured from the chemical potential),

\[
\frac{\partial}{\partial t} h(x) + \nabla \cdot J_Q = 0. \tag{A4}
\]

In the Fourier \( (q) \) and imaginary-time \( (\tau) \) representation, \( \partial_\tau h(-q) = h q \cdot J_Q(-q) \). Using this in Eq. (A3) after integration by parts,

\[
K_0(q, i\omega_\lambda) = \frac{\hbar q_i}{i\omega_\lambda} [K_i(q, i\omega_\lambda) - K_i(q, 0)], \tag{A5}
\]

where

\[
K_i(q, i\omega_\lambda) = \int_0^{\beta T} d\tau e^{i\omega_\lambda \tau} \langle \hat{\tau} \hat{\lambda}(\tau) j_Q(\tau) \rangle. \tag{A6}
\]

The factor \( i\omega_\lambda \) in Eq. (A5) is combined with \( \psi_q \) in Eq. (A2) to yield \( \nabla \psi \). When \( \nabla \psi \) is uniform and static, we can take the limit \( q \to 0 \) and \( \omega \to 0 \) in the coefficient [Eq. (A6)] and obtain

\[
\langle \hat{A} \rangle _\psi = \lim_{\omega \to 0} \frac{K_i(\omega + i0) - K_i(0)}{i\omega} (-\nabla \psi), \tag{A7}
\]

\[
K_i(i\omega) = \int_0^{\beta T} d\tau e^{i\omega \tau} \langle \hat{\tau} \hat{\lambda}(\tau) J_Q(\tau) \rangle, \tag{A8}
\]

where \( J_Q \equiv J_Q(q = 0) \) is the total heat current. An explicit form of \( J_Q \) is studied in Appendix B and given in Eq. (20).

APPENDIX B: EXPRESSIONS OF HEAT-CURRENT DENSITY

Here, we derive the expression for the heat-current density, \( J_Q \), using Eq. (A4). Let us consider the following two forms of Hamiltonian density,

\[
h^{(1)}(x) = \frac{\hbar^2}{2m} (\nabla c)^*(\nabla c) + \nabla^2 Vc, \tag{B1}
\]

\[
h^{(2)}(x) = -\frac{\hbar^2}{4m} [c^\dagger (\nabla^2 c)^* + (\nabla^2 c)^\dagger c] + \nabla^2 Vc, \tag{B2}
\]

where

\[
V(r) = -Mn \cdot \sigma - \mu + V_{\text{imp}}(r). \tag{B3}
\]

They differ from each other by a total divergence,

\[
\hat{h}^{(1)}(x) - \hat{h}^{(2)}(x) = \frac{\hbar^2}{4m} \nabla^2 \rho, \tag{B4}
\]
where $\rho = c^\dagger c$ is the (number) density. Using the field equation,

$$i\hbar \dot{c}(x) = -\frac{\hbar^2}{2m} \nabla^2 c + V c,$$

and its conjugate, we can rewrite the above as follows;

$$\hat{h}^{(1)}(x) = \frac{i\hbar}{2} (c^\dagger \dot{c} - \dot{c}^\dagger c),$$

$$\hat{h}^{(2)}(x) = \frac{i\hbar}{2} (c^\dagger \dot{c} - \dot{c}^\dagger c).$$

To derive the expression for $\dot{J}_Q$, we use Eq. (A4) and first take a time derivative of Eqs. (B1) and (B2), and then use Eq. (B5). The results are

$$\dot{J}^{(1)}_Q(x) = -\frac{\hbar^2}{2m} [c^\dagger (\nabla c) + (\nabla c^\dagger) \dot{c}],$$

$$\dot{J}^{(2)}_Q(x) = -\frac{\hbar^2}{2m} [c^\dagger (\nabla c) + (\nabla c^\dagger) \dot{c}] + \frac{\hbar^2}{4m} \nabla \dot{\rho},$$

$$= \frac{\hbar^2}{4m} \lim_{x' \to x} (\nabla - \nabla') (\dot{c}(x) c^\dagger(x'),$$

where $x = (r, t), x' = (r', t')$. In Fourier components ($r \to q$), they read

$$\dot{h}^{(1)}(q) = \frac{i\hbar}{2} \sum_k (c_k^\dagger \dot{c}_k - \dot{c}_k^\dagger c_k) - \frac{\hbar^2}{4m} q^2 \rho_q,$$

$$\dot{h}^{(2)}(q) = \frac{i\hbar}{2} \sum_k v_k (c_k^\dagger \dot{c}_k - \dot{c}_k^\dagger c_k) - \frac{\hbar^2}{4m} i q \dot{\rho}_q,$$

$$= \frac{\hbar^2}{4m} \xi_k,$$

$$\dot{J}_Q^{(q)} = q \to 0,$$
account only \( \varphi_1 \) (including vertex corrections), in accordance with the observation made around Eq. (26).

**APPENDIX D: EQUILIBRIUM EXCHANGE TORQUE**

Here we calculate the equilibrium exchange torque, Eq. (50), to show that it indeed has the same coefficient \( c \) [Eq. (45)] as the problematic term, Eq. (48). In the presence of a static magnetization texture, Eq. (10), the equilibrium spin density to the first order in \( \mathbf{u}_q \) reads

\[
\langle \hat{\sigma}^q \rangle \sigma_{ij} = M J^{\alpha\beta}(q) \mathbf{u}_q^\alpha, \tag{D1}
\]

where

\[
J^{\alpha\beta}(q) = -T \sum_n \sum_k \text{tr}[\sigma^\alpha G_{k+q}(i\varepsilon_n)\sigma^\beta G_k(i\varepsilon_n)]
\]

\[
= J^{\alpha\beta}(0) + J^{\alpha\beta}_{ij} \varphi_{ij} + O(q^4). \tag{D2}
\]

In the second line, we expanded \( J^{\alpha\beta}(q) \) with respect to \( q \) with coefficients \( J^{\alpha\beta}(0) = (\rho_s/M)\delta^{\alpha\beta} \), where \( \rho_s = n_+ - n_- \) is the conduction electron spin polarization for uniform \( \mathbf{n} \), and

\[
J^{\alpha\beta}_{ij} = \frac{1}{2} T \sum_n \sum_k v_i v_j \text{tr}[\sigma^\alpha G G_{k+q} \sigma^\beta G_k]
\]

\[
= \delta^{\alpha\beta} T \sum_n \sum_k v_i v_j (G_1 G_k)^2 \tag{D3}
\]

with \( G \equiv G_k(i\varepsilon_n) \) and \( G_\alpha \equiv G_{k\alpha}(i\varepsilon_n) \). Standard procedure leads to

\[
J^{\alpha\beta}_{ij} = -\frac{1}{\pi} \delta^{\alpha\beta} \int_{-\infty}^{\infty} d\varepsilon f(\varepsilon) \sum_k v_i v_j \text{Im}[G^\alpha_1(\varepsilon)G^\beta_0(\varepsilon)]^2
\]

\[
= -\delta^{\alpha\beta} \frac{1}{M^2} \int_{-\infty}^{\infty} d\varepsilon f(\varepsilon) C(\varepsilon)
\]

\[
= -\frac{c}{M^2} \delta^{\alpha\beta}, \tag{D4}
\]

where we used Eqs. (40) and (45). This gives the spin density,

\[
\langle \hat{\sigma} \rangle \sigma = \rho_s \hat{z} + \langle \hat{\sigma} (q) \rangle \sigma = \rho_s \hat{z} + (c/M) \nabla^2 \mathbf{u} = \rho_s \mathbf{n} + (c/M) \nabla^2 \mathbf{n}, \tag{50}
\]

and the torque, Eq. (50).

**APPENDIX E: RESPONSE TO SCALAR POTENTIALS**

Here we directly calculate the linear response to the scalar potentials of electric (\( \phi \)) and gravitational (\( \psi \)) fields. This confirms our assertion that no terms proportional to \( \psi \) arise (next to those with \( \partial_\alpha \hat{\psi} \)), which is crucial for the procedure proposed in Sec. VI. It also serves as a check of Eqs. (A7) and (A8).

The linear response of the s-electron spin density to \( \phi \) or \( \psi \) may be expressed as

\[
\langle \hat{\sigma} \rangle_\phi = -e (A_\phi - i\omega B_\phi)/M, \tag{E1}
\]

\[
\langle \hat{\sigma} \rangle_\psi = (A_\psi - i\omega B_\psi)/M, \tag{E2}
\]

respectively, retaining the terms up to first order in \( \omega \), i.e., the frequency of \( \phi \) or \( \psi \). The coefficients are

\[
A_\phi = -C_0 \partial_\alpha \partial_\beta \rho_s, \tag{E3}
\]

\[
B_\phi = C_0 (\nabla^2 \mathbf{n})_\phi + [B_0 \partial_\alpha \mathbf{n} - A_0 (\mathbf{n} \times \partial_\alpha \mathbf{n})] \partial_\beta \phi, \tag{E4}
\]

\[
A_\psi = (c - C_1) \partial_\alpha \partial_\beta \rho_s \psi - e (\nabla^2 \mathbf{n}) \psi, \tag{E5}
\]

\[
B_\psi = C_1 (\nabla^2 \mathbf{n}) \psi + [B_1 \partial_\alpha \mathbf{n} - A_1 (\mathbf{n} \times \partial_\alpha \mathbf{n})] \partial_\beta \psi, \tag{E6}
\]

where \( A_\alpha, B_\alpha, C_\alpha \), and \( c \) are given by Eqs. (44) and (45). The second term in Eq. (E5) is a correction similar to the second term in Eq. (26) treating the heat vertex by the factor \( i(\varepsilon_n + \omega)/2 \). Each factor \( (i\omega)^{-1} \) in Eqs. (E4) and (E6) reflects conservation of electron number and energy, respectively, and comes from ladder-type vertex correction [45,46]. Therefore, even in the static limit, \( \omega \rightarrow 0 \), the \( B_\phi \) and \( B_\psi \) terms survive in Eqs. (E1) and (E2) and lead to

\[
M \langle \hat{\sigma} \rangle_\phi = -e [B_0 - C_0] \partial_\alpha \mathbf{n} - A_0 (\mathbf{n} \times \partial_\alpha \mathbf{n})] \partial_\beta \phi, \tag{E7}
\]

\[
M \langle \hat{\sigma} \rangle_\psi = [B_1 - C_1 + c] \partial_\alpha \mathbf{n} - A_1 (\mathbf{n} \times \partial_\alpha \mathbf{n})] \partial_\beta \psi. \tag{E8}
\]

Note that the terms proportional to \( \phi \) or \( \psi \) (but not \( \partial_\alpha \phi \) or \( \partial_\alpha \psi \)) cancel exactly, which reflects the adiabatic nature of the Kubo formula (see Appendix F) and is crucial for the procedure described in Sec. VI. Torques obtained from Eqs. (E7) and (E8) agree with Eqs. (46) and (47), confirming the validity of Eqs. (A7) and (A8).

**APPENDIX F: RESPONSE TO STATIC AND UNIFORM SCALAR POTENTIALS**

In this Appendix, we consider \( \phi \) and \( \psi \) that are static and uniform. The response to such potentials can be compared with equilibrium theory.

The perturbation is described by the Hamiltonian

\[
H' = -e N \phi + K \psi, \tag{F1}
\]
where $K = H - \mu N$, $N$ is the total number of electrons, and $H$ is the Hamiltonian of the (unperturbed) system. (We neglect the nonlinear perturbation proportional to $\phi \psi$.) Let us consider the adiabatic and isothermal response of a physical quantity $\hat{A}$,

$$\delta (\hat{A})_{ad} = e^{\chi^B_0(0)} \phi - \chi^B_0(0) \psi, \quad (F2)$$

$$\delta (\hat{A})^T = e^{\chi^T_0(0)} \phi - \chi^T_0(0) \psi, \quad (F3)$$

respectively. The response functions are given by the static limit of

$$\chi^B_0(\omega) = \frac{i}{\hbar} \int_0^\infty dt e^{i(\omega + i\delta)(t)} \langle [\hat{A}(t), \hat{B}] \rangle, \quad (F4)$$

$$\chi^T_0(i\omega_n) = \int_0^{\beta_0} d\tau e^{i\omega_n \tau} \langle T_\tau \hat{A}(\tau) \Delta \hat{B} \rangle, \quad (F5)$$

where $\Delta \hat{B} = \hat{B} - \langle \hat{B} \rangle$, with $\hat{B} = N$ or $K$ [47]. Since $\hat{B}$ commutes with $K$, we have

$$\chi^B_0(\omega) = 0, \quad (F6)$$

$$\chi^T_0(i\omega_n) = \beta_0 \langle \Delta \hat{A} \Delta \hat{B} \rangle \delta_{\omega_n,0}, \quad (F7)$$

where $\Delta \hat{A} = \hat{A} - \langle \hat{A} \rangle$. Therefore, the adiabatic response vanishes,

$$\delta (\hat{A})_{ad} = 0. \quad (F8)$$

The Kubo formula corresponds to this case [47]. The isothermal response (F7) can be expressed by the thermodynamic formula,

$$\chi^T_0(0) = \frac{\partial}{\partial \mu}(\hat{A}), \quad (F9)$$

$$\chi^B_k(0) = -\beta_0 \frac{\partial}{\partial \beta_0}(\hat{A}) = T \frac{\partial}{\partial T}(\hat{A}), \quad (F10)$$

for $B = N$ and $K$, respectively, leading to

$$\delta (\hat{A})^T = e^{\phi} \frac{\partial}{\partial \mu}(\hat{A}) - \psi T \frac{\partial}{\partial T}(\hat{A}). \quad (F11)$$

This is natural since $e^{-\beta_0(K+H')} = e^{-\beta_0[(1+\psi)K - e\phi N]}$ is nothing but $e^{-\beta_0K} = e^{-\beta_0[H - e\phi N]}$ with $\beta_0$ and $\mu$ modified by $\delta \beta_0 = \beta_0 \psi$ and $\delta \mu = e\phi$, respectively.

Here we are interested in $\hat{A} = \hat{a}_+^T$ with equilibrium value (see Appendix D)

$$\langle \hat{a}_+ \rangle = c \hat{\nabla}_{\parallel}^2 n / M, \quad (F12)$$

where $c$ is given by Eq. (45). Since $\partial c / \partial \mu = C_0$ and $T(\partial c / \partial T) = C_1$, the isothermal response is given by

$$\delta \langle \hat{a}_+ \rangle^T = (e\phi C_0 - \psi C_1) \hat{\nabla}_{\parallel}^2 n / M. \quad (F13)$$

The susceptibilities read $\chi^T_0 = C_0 \hat{\nabla}_{\parallel}^2 n / M$ and $\chi^B_k = C_1 \hat{\nabla}_{\parallel}^2 n / M$. The adiabatic susceptibilities, $\chi^T_{ad}$ and $\chi^B_{ad}$, are obtained by subtracting the corrections due to changes in $T$ and $\mu$ [47], giving $\chi^T_{ad} = \chi^T_k = 0$, consistent with Eq. (F8). We recognize these isothermal components (F13) in Eqs. (E3) and (E5), which are eventually canceled by the corresponding terms in Eqs. (E4) and (E6), resulting in a vanishing adiabatic response to static and uniform $\phi$ and $\psi$.

[26] Equivalent relations can be written for the Stoner model.
[34] The letter $\beta$ is used for the coefficient of the $\beta$ term as well as for the spin index (such as $\varepsilon^{\alpha\beta}$ and $u^{\beta}q$), but we hope no confusion will arise; the latter appears only as indices while the former never appears as indices.
[36] In Eq. (32), $\sigma^{\beta}$ can be moved to the position adjacent to $\sigma^{\alpha}$ by reversing the spin, $\sigma^{\uparrow} \rightarrow -\sigma^{\uparrow}$, in $G$, which allows making use of $\sigma^{\alpha}\sigma^{\beta} = \delta^{\alpha\beta} + i\varepsilon^{\alpha\beta\gamma}$. This dependence on $\alpha$ and $\beta$ was exploited in Eqs. (21) and (22).
[37] Since $f(\varepsilon)$ is multiplied by a total derivative $\partial C(\varepsilon)$ in the Fermi-sea term in $\tilde{b}$ [second term in Eq. (35)], this term can be transformed into a Fermi-surface term by partial integration. However, this is specific to the present case; in general such a total-derivative form does not appear at the formal Green function level, see Ref. [17].
[38] We define a closed circuit in terms of an electrical short, i.e., a situation in which the two ends of the sample have different temperatures but identical electrochemical potential (as in Ref. [6]). In other words, the circuit is closed by either an ideal ammeter (closed circuit) or voltmeter (open circuit).
[39] If we neglect magnetic impurities, $\tau^{-1} \propto n_0$ [Eq. (12)] and thus $\sigma_0 \propto \sum \sigma n_0 \tau_0 \propto \sum \sigma \varepsilon n_0 = 2M$ does not depend on $\varepsilon_0$. Magnetic impurities give rise to $\varepsilon_0$-dependent terms in $\sigma_0$ with a relative magnitude $\sim (n_0 u_0^2 S_{\text{imp}}/n_i u_i^2)^2$.
[40] Note that $s$ is the off-shell energy and does not need to correspond to real energy levels of the system.
[41] If $D(\varepsilon)$ were a (single-particle) density of states, $\chi_{\text{sea}}$, $\chi_{\text{sea}}^T$, and $\Phi$ [defined in Eq. (85)] would represent the number, entropy, and the grand-canonical free energy, respectively. The ‘unsubtracted’ $\chi_{\text{sea}}^T$ [first term of $\chi_{\text{sea}}^T$ in Eq. (80)] then corresponds to an energy, which does not vanish at zero temperature because of Fermi degeneracy.
[42] With $\Psi \equiv \int_{-\infty}^{\infty} d\varepsilon f(\varepsilon)B(\varepsilon)$, we have $\chi_{\text{surf}} = \partial \Psi / \partial \mu$ and $\chi_{\text{surf}}^T = T(\partial \Psi / \partial T)$.
