1. INTRODUCTION

This master’s thesis investigates the equivalence of streams as presented by [EHK11, Ste08]. In the process some morphic properties of the Toeplitz words as first described by [JK69] are discovered. The terminology of theoretical computer science and mathematics shows some discrepancies: In theoretical computer science words of infinite length are usually called streams and referred to as symbolic sequences in mathematics. Similarly, morphisms are what mathematicians usually refer to as substitutions. Notation is formally introduced starting in section 2 but will be informally used in the introduction.

The first part of this section is a proper introduction into the subject. The two subsections will be used to describe two original results: The first has to do with prime degrees, the second one has to do with arithmetic subsequences.

Finite state machines were first described by neurophysiologists Warren McCulloch and Walter Pitts in the 1943 paper “A Logical Calculus Immanent in Nervous Activity”. Their pioneering work made significant contributions to the neural network theory, theory of automata, theory of computation and cybernetics. Later, two computer scientists, G.H. Mealy and E.F. Moore, generalized the theory to much more powerful machines in separate papers, published in 1955-56. The finite-state machines, Mealy machine and the Moore machine, are named in recognition of their work.¹

¹“The Intellectual Excitement of Computer Science”, Eric Roberts, Stanford University

Date: May 2, 2011.
Automata theory emerged to be important in the field of compiler design. It is closely tied to the notion of regular languages. One focus of this thesis is the ordering obtained by applying transducers, a special type of finite state machine, to streams. The type of transducer considered in this document has been called pure sequential transducer in [Sak09], simply finite-state transducer in [AS03] and also sequential transducer in other literature. Denote $\Sigma^*$ the collection of all words over some finite alphabet $\Sigma$. In this thesis the term transducer will refer to:

Definition 1.1. A finite state transducer (which will be abbreviated to FST or transducer) is a sextuple $A = (Q, \Sigma, \delta, q_0, \Delta, \lambda)$ where

- $Q$ is a finite set of states
- $\Sigma$ is a finite set, the input alphabet
- $\delta \subseteq Q \times \Sigma \times \Delta^* \times Q$ is a transition relation
- $q_0 \in Q$ is the initial state
- $\Delta$ is a finite set, the output alphabet
- $\lambda : Q \times \Sigma \to \Delta^*$ is the output function

Suppose $q_1, q_2 \in Q, a \in \Sigma, b \in \Delta^*$ then

$$(q_1, a, b, q_2) \in \delta$$

describes the edge from state $q_1$ to state $q_2$ that takes input $a$ and generates output $b$. Assume the transition relation to be deterministic: For all $q_1 \in Q, a \in \Sigma$ there is exactly one $q_2 \in Q, b \in \Delta^*$ such that

$$(q_1, a, b, q_2) \in \delta$$

An elementary example of a transducer that performs the shift operator $\sigma$ on a infinite word (stream) is given in Figure 1. Transitions between states are made by following the arrow, where $a|a'$ takes input $a$ and gives output $a'$. Let $a, b \in \Sigma^\infty$ be single-sided streams over some alphabet $\Sigma$. Suppose that there is some transducer $A$ such that $A(a) = b$, then this is indicated by the notation:

$$a \triangleright b$$

Suppose there are some transducers $A, B$ such that $A(a) = b$ and $B(b) = a$. Then $a, b$ are equal under transducers and share the same degree. This is indicated by:

$$a \bowtie b$$

Then $\triangleright$ induces a partial ordering on streams, where $\bowtie$ indicates equivalence between streams. Note that the alphabets $\Sigma, \Delta$ will be restricted to $\{0, 1\}$, as higher order alphabets do not change the partial ordering as mentioned by [EHK11]. The degree of stream $a$ includes the sequences that $a$ can both transduce to and which can

\[ \text{Figure 1. Example of a transducer. It follows that } a \triangleright \sigma(a) \text{ for any stream } a. \]
be transduced back to $a$ as well. There are countable many different transducers, but there are uncountable many infinite words. So there are uncountably many degrees. Some classes of streams are closed under transducers:

- morphic streams, [AS03]
- eventually recurrent streams, [EHK11]

A special notion is reserved for degrees that include every transduction of every sequence in the degree, excluding any periodic sequences. A degree is called prime if for every sequence in the degree the output under a transducer (the transduct) can be transduced back to the original sequence, or is a periodic sequence. Finite sequences are counted as periodic. One of the main results in [EHK11] is the fact that the degree of $\Pi$ is prime:

$$\Pi = 10100100010000100000\ldots$$

A proof is given in section 9 of this document. Eventually periodic and periodic sequences are transducer equivalent because transducers can add and remove arbitrarily long prefixes. The degree of (eventually) periodic sequences is also prime, as every sequence can be transduced to a periodic sequence. The degree of periodic sequences will be considered the zero or trivial degree.

Two other known structures exists in the transducer ordering of streams: A collection of streams $\{A_i\}_{i \in \mathbb{N}}$ is called an infinite ascending chain if for every $i$:

\[
A_{i+1} \triangleright A_i \quad A_i \not\triangleleft A_{i+1}
\]

Opposed to this is the notion of an infinite descending chain for a collection $\{D_i\}_{i \in \mathbb{N}}$ holds:

\[
D_i \triangleright D_{i+1} \quad D_{i+1} \not\triangleleft D_i
\]

Examples of such chains are given in [EHK11]. In Section 10 an infinite descending chain based on the classic Fibonacci sequence is constructed, which has not been mentioned before. The degree of the Thue-Morse sequence includes the period-doubling sequence $v_2$, and is conjectured to be prime by [EHK11]. The Thue-Morse word (TM) is the fixed point of substitution $g$, starting on zero:

\[
g(0) \rightarrow 01 \\
g(1) \rightarrow 10 \\
TM = g^\infty(0) = 01010010011010110\ldots
\]

The $n$-th letter of Thue-Morse is equal to the parity of the number of ones in the binary expansion of $n$, with even giving zero and odd a one. See lemma 3.3 for a proof. The degree of Thue-Morse includes the period doubling word $v_2$:

\[
TM \circ v_2
\]

The period doubling word $v_2$ is the fixed point of the following substitution $k$:

\[
k(0) \rightarrow 01 \\
k(1) \rightarrow 00 \\
v_2 = k^\infty(0) = \{\max_b 2^b|n\}_{n \in \mathbb{N}} = \{v_2(n)\}_{n \in \mathbb{N}} = 0100010101000100\ldots
\]
The $n$-th letter of the period doubling sequence is given by the parity of the number of leading zeros in the binary expansion of $n$. A proof is given in lemma 3.4. The notation for $v_2$ is ambiguous: $v_2$ refers to the period doubling sequence but also to the function $v_2(n)$ which determines the $2$-adic valuation of $n$.

1.1. **Prime streams.** It is shown in [Ste08] that the degree of the Thue-Morse sequence includes all of its arithmetic subsequences. That is, for any integers $a, b > 0$ holds:

$$TM \circ \{TM(a + bn)\}_{n \in \mathbb{N}}$$

For a proof see theorem 7.7. One would expect a similar result for the period doubling sequence, but this turns out to be difficult. For the period doubling sequence it is shown as an original result that for integers $a, b > 1$ with $b$ odd:

$$v_2 \succ \{v_2(a + bn)\}_{n \in \mathbb{N}} \circ \{v_2(2a + bn)\}_{n \in \mathbb{N}}$$

The first line however, is true for any stream. The second line is proven in section 8. For $b$ even, $\{v_2(a + bn)\}_{n \in \mathbb{N}}$ is either periodic or is transducer equivalent to $b$ odd. At this moment it is not known if $\{v_2(a + bn)\}_{n \in \mathbb{N}} \succ v_2$ holds in general. If this were not to be the case, then the degree of Thue-Morse would not be prime. If the affirmative would be the case, then this does not assert the prime property of Thue-Morse.

1.2. **Arithmetic subsequences.** Suppose Thue-Morse would be prime. One of the least implications would be that Thue-Morse, the period doubling sequence and all of the arithmetic subsequences would be transducer equivalent. To get a feeling of the objects involved, I tried making a (counter) example to the stated claims. I conjured that perhaps the morphisms associated with these sequences could be indicators for transducer equivalence. As little was known regarding the morphic structure of the mentioned sequences, I decided describing these morphisms would be a first step.

The arithmetic subsequences of the period doubling word $v_2$ exhibit a property that has not been mentioned in literature before. To understand the property, the following definition is necessary:

**Definition 1.2.** The rotated Toeplitz substitution $\rho_{a, k^m}$ is a substitution created by taking the iterated substitution $k^m$ and rotating it by $a$

$$k^m(c) = d_0d_1 \ldots d_n$$

$$\rho_{1,k^m}(c) = d_n d_0 \ldots d_{n-1}$$

$$\rho_{a,k^m}(c) = d_{n-a+1} \ldots d_n d_0 \ldots d_{n-a}$$

where $c \in \{0, 1\}$.

The rotated Toeplitz substitution is a substitution in its own right, as opposed to being an operator on the Toeplitz substitution. For example:

$$k^3(0) = 01000101$$

$$k^3(1) = 01000100$$

$$\rho_{1,k^3}(0) = 10100010$$

$$\rho_{1,k^3}(1) = 00100010$$

$$\rho_{2,k^3}(0) = 01010001$$

$$\rho_{2,k^3}(1) = 00010001$$
Now fix some \( m \in \mathbb{N} \) and an integer \( 0 < q < 2^m - 1 \). Then by theorem 3.8 \( \{ v_2(q + (2^m - 1)n) \}_{n \in \mathbb{N}} \) is the fixed point of
\[
\rho_{q+1,k^m}
\]
starting on \( v_2(q) \). In other notation:
\[
\rho_{q+1,k^m}^\infty(v_2(q)) = \{ v_2(q + (2^m - 1)n) \}_{n \in \mathbb{N}} = \{ v_2\left(\frac{q}{2^m - 1} + n\right) \}_{n \in \mathbb{N}}
\]
For example, \( \{ v_2\left(\frac{1}{3} + n\right) \}_{n \in \mathbb{N}} \) is the fixed point of the substitution \( \rho_{2,k^2} \):
\[
\begin{align*}
k^2(0) &= 0100 \\
k^2(1) &= 0101 \\
\rho_{2,k^2}(0) &= 0001 \\
\rho_{2,k^2}(1) &= 0101
\end{align*}
\]
A 2-adic rational number other than zero may be associated with an arithmetic subsequence of the period doubling word. Zero is not included because \( v_2(0) \) is not properly defined. Any non-zero 2-adic rational number \( r \) has an associated Toeplitz sequence:
\[
\{ v_2\left(\frac{r}{2^l - 1} + n\right) \}_{n \in \mathbb{N}}
\]
The number 1 is associated with the period doubling sequence itself:
\[
\{ v_2(1 + n) \}_{n \in \mathbb{N}} = \{ v_2(n) \}_{n \in \mathbb{N} \geq 0} = k^\infty(0)
\]
For \( r \geq 2^l - 1 \), the associated sequence is a suffix of
\[
\{ v_2\left(\frac{r'}{(2^l - 1)} + n\right) \}_{n \in \mathbb{N}}
\]
where \( r' \in \{ 1, 2, \ldots, 2^l - 1 \} \) such that \( r' = r \mod 2^l - 1 \). Applying a rotated Toeplitz substitution to an arithmetic subsequence of the period doubling word yields another arithmetic subsequence of the period doubling word. Theorem 4.1 shows that:
\[
\rho_{q+1,k^m}(\{ v_2\left(\frac{r}{2^l - 1} + n\right) \}_{n \in \mathbb{N}}) = \{ v_2\left(\frac{2^m r}{2^l - 1} - q + n\right) \}_{n \in \mathbb{N}}
\]
The rotated Toeplitz substitution theorems also apply to a generalization of \( v_2 \). Let \( p \) be a prime, then:
\[
\begin{align*}
k_p(0) &= 0^p - 1 \\
k_p(1) &= 0^p - 1 \\
v_p &= k^\infty_p(0) \\
&= \{ \max_b p^b | n \mod 2 \}_{n \in \mathbb{N} \geq 0}
\end{align*}
\]
For more details see section 3, section 4 and appendix A. A more general connection between streams and morphisms is provided by a theorem of Cobham. It connects the notion of \( k \)-automatic sequences with fixed points of morphisms. Thue-Morse, the period doubling word and their arithmetic subsequences are themselves 2-automatic sequences:
Theorem 1.3 (Cobham). Let $k \geq 2$. Then a sequence is $k$–automatic if and only if it is the image, under a 1-uniform substitution, of a fixed point of a $k$-uniform substitution.

For a proof see section 5. The morphisms usually run over higher-order alphabets and a coding on the fixed point of said morphism is needed to construct the automatic sequence. The arithmetic subsequences of $v_p$ can be described as proper fixed points of rotated morphisms: No coding is needed. This specific property has not been described before. The connection between operations on p-adic numbers and applying morphisms on streams as described in theorem 4.1 is novel.

The arithmetic subsequences of Thue-Morse can also be described elegantly as proper fixed points of morphisms. I have not found the time to include this result in my thesis.

Further research on morphisms could consider general subsequences of streams. Morphic streams different from Thue-Morse and the period doubling sequence should also been considered. One problem would be: characterize streams that are transducer equivalent to all their arithmetic subsequences.

2. On words

Let $\Sigma$ be a finite collection of distinct objects, a so called set. Let $\Sigma^m$ be the set of all finite sequences $a_1 \ldots a_m$ with $a_j \in \Sigma$ for $1 \leq i \leq m$. Elements of $\Sigma$ are called letters, and elements of $\Sigma^m$ are called words over $\Sigma$ of length $m$. Note: $m$ is a natural number; $\Sigma^0 = \epsilon$, where $\epsilon$ is the empty word having no letters, and $\Sigma^1$ can be identified with $\Sigma$. The set $\Sigma^m$ can be identified with the cartesian product $\Sigma \times \Sigma \times \ldots \times \Sigma$, but its elements are written without the usual commas and parentheses. Taken from [Chi09].

Definition 2.1. Write

$$
\begin{align*}
\Sigma^+ & = \cup_{m \geq 1} \Sigma^m \\
\Sigma^* & = \cup_{m \geq 0} \Sigma^m \\
& = \Sigma^+ \cup \epsilon
\end{align*}
$$

If $a = a_1 \ldots a_m, b = b_1 \ldots b_n \in \Sigma^*$, define $ab \in \Sigma^{m+n}$ to be $a_1 \ldots a_m b_1 \ldots b_n$. This gives a (closed) binary operation on $\Sigma^*$ and $\Sigma^+$ called concatenation. It is associative: $a(bc) = (ab)c$ and $ac = ca = a$. Thus $\Sigma^+$ is a semigroup called the free semigroup on $\Sigma$. A semigroup with an identity element (word $\epsilon$) is called a monoid. $\Sigma^*$ is a monoid and is called the free monoid over $\Sigma$. Recall that a monoid such that every element has a inverse is called a group. Denote the length of a word $a$ by $|a|$. Define $a^n$ with $n \in \mathbb{N}$ by: $a^0 = \epsilon, a^{n+1} = a^n a$.

If $a$ is a word over the set $\Sigma$ (which is also called the alphabet), a factor of $a$ is a word $c \in \Sigma^*$ such that $a = bcd$ for some $b,d \in \Sigma^*$. If $b = \epsilon$, then $c$ is called a prefix of $a$. If $d = \epsilon$, then $c$ is called a suffix of $a$. If $c \neq a$ then $c$ is called a pure factor.

A language is any subset $L \subseteq \Sigma^*$. $L$ is a collection of words over the alphabet $\Sigma$. For example, we may denote $L = \{1^n0^n|n \in \mathbb{N}\}$. Then $L$ is the language over the alphabet $\{0,1\}$ containing all words that are constructed by taking ones followed by an equal amount of zeros.

Words may also be of infinite length: Suppose $a \in \Sigma^\infty$. Then $a$ is a (single sided) infinite word or stream and note $a = a_0a_1a_2 \ldots$ with $a_i \in \Sigma$ for $\forall i \in \mathbb{N}$.

Denote $s_k(n)$ the expansion of integer $n$ over base $k$, with the most significant bit to the left. Each $s_k(n)$ starts with an 1 except for $s_k(0) = \epsilon$.

Suppose $a \in \{0,1\}^*$ then $\overline{a}$ denotes the conjugate of $a$, given by interchanging every 1 with 0 and vice versa.
3. On Toeplitz substitutions

**Definition 3.1.** A substitution is a map \( h : \Sigma^+ \to \Delta^* \) such that
\[
h(ab) = h(a)h(b)
\]
for all \( a, b \in \Sigma^+ \).

In computer science, substitutions are usually referred to as *morphisms*. For example see [AS03]. Suppose that for all \( a \in \Sigma \) the length of the substitution is constant: \( |h(a)| = k \) for some \( k \in \mathbb{N} \). Then the substitution \( h \) is of uniform length \( k \).

**Definition 3.2.** A substitution is prolongable on symbol \( a \in \Sigma \) if \( h : \Sigma^+ \to \Sigma^* \) for some alphabet \( \Sigma \) and if for some \( a \in \Sigma \) it holds that \( h(a) = ab \) for some \( b \in \Sigma^* \) such that \( h^n(b) \neq \epsilon \) for all \( n \in \mathbb{N} \).

Denote the limit of a prolongable substitution by
\[
\lim_{n \to \infty} h^n(a) = abh(b)h^2(b)\ldots.
\]
Note that \( \lim_{n \to \infty} h^n(a) \) is a fixed point of prolongable substitution \( h \), because
\[
h(\lim_{n \to \infty} h^n(a)) = h(abh(b)h^2(b)\ldots) = h(a)h(b)h^2(b)h^3(b)\ldots = abh(b)h^2(b)h^3(b)\ldots = \lim_{n \to \infty} h^n(a)
\]
Denote the *Thue-Morse substitution* \( g : \{0, 1\}^+ \to \{0, 1\}^* : \)
\[
g(0) \to 01
\]
\[
g(1) \to 10
\]
Then iterate the substitution on starting word \( w = 0 \) in the following fashion:
\[
g(0) = 01
\]
\[
g^2(0) = 0110
\]
\[
g^3(0) = 01101001
\]
\[
g^4(0) = 0110100110010110
\]
\[
\ldots \ldots
\]
The Thue-Morse substitution is prolongable on zero\(^2\) and by taking the limit the infamous *Thue-Morse stream* is obtained:
\[
\lim_{n \to \infty} g^n(0) = 01101001100101101001011100110011010010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001001100110010011001100100110011001...\

The Thue-Morse stream was first implicitly described in a 1851 paper of Prouhet, and was later independently discovered most notably by Thue (1906) and Morse (1921) [AS99]. For historical reasons it is often called the Thue-Morse word. The Thue-Morse word has some amazing properties and shows up in seemingly unrelated subjects. It is an infinite non-periodic word that is *strongly cubefree*: There is no factor in Thue-Morse of the form \( x^2a \) where \( a \) is the first letter of the non-empty word \( x \). For every factor that does occur in the Thue-Morse sequence however, it occurs infinitely often. There are several ways to construct the Thue-Morse word. For the sake of future discussion, we will exhibit one other way to construct the Thue-Morse sequence. For a more complete overview of the Thue-Morse word see [AS99, Ste08, Klo02].

\(^2\)It is also prolongable on 1. The limit is equal to the conjugate of Thue-Morse.
Lemma 3.3. Denote $s_2(n)$ the base-2 expansion of integer $n$. Let

$$T(n) = \{\text{number of occurrences of } 1 \text{ in } s_2(n)\} \mod 2$$

Then $\{T(n)\}_{n\in\mathbb{N}}$ equals the Thue-Morse word.

Proof. Proof by induction. It is clear that

$$g^m(0) = T(0), T(1), \ldots, T(2^m - 1)$$

is true for $m = 2$. Assume that for a given $m$ the equation holds. It is to be shown the equation also holds for $m + 1$. From the definition of the function $TM()$ follows that

$$TM(2n) = TM(n)$$
$$TM(2n + 1) = 1 - TM(n)$$

Compute $g^{m+1}(0)$ by using the induction hypothesis, expanding the substitution using the above equations:

$$g^{m+1}(0) = g(g^m(0))$$
$$= g(TM(0), TM(1), \ldots, TM(2^m - 1))$$
$$= TM(0), 1 - TM(0), TM(1), 1 - TM(1), \ldots, TM(2^m - 1), 1 - TM(2^m - 1))$$
$$= TM(0), TM(1), TM(2), TM(3), \ldots, TM(2^{m+1} - 2), TM(2^{m+1} - 1)$$

□

It follows from a deep result of [Mah29] that $\xi = \sum_{n=0}^{\infty} T(n) 2^{-n}$ is a transcendental number. Later, this fact was proven in a more concise way by [Dek77]. It should be noted that the works of Mahler initially attracted the attention of a small group of specialists. Only relatively recently has his work become more popular. Currently, some of Mahler’s results and conjectures are the focus of intense research.\(^3\)

There is another substitution of uniform length 2 that shows similar properties to Thue-Morse, the Toeplitz substitution $k$:

$$k(0) = 01$$
$$k(1) = 00$$

Then call $\lim_{n \to \infty} k^n(0)$ the Toeplitz word:

$$\lim_{n \to \infty} k^n(0) = 0100010100010001010001010001010001000100010001\ldots$$

The Toeplitz word is also known as the period doubling sequence.

Lemma 3.4. Define for $n \in \mathbb{N}_0$ :

$$ord_2(n) = \max\{b : 2^b | n\}$$
$$v_2(n) = \{ord_2(n)\} \mod 2$$

Then $\{v_2(n)\}_{n\in\mathbb{N}_0}$ denotes the period doubling word.

Proof. Proof by formal induction. It is clear that

$$k^m(0) = v_2(1), v_2(1), \ldots, v_2(2^m)$$
holds for \( m = 2 \) and \( m = 1 \). Assume the above holds for \( m \) and \( m - 1 \). It shall be shown the equation also holds for \( m + 1 \). From the definition of \( v_2(n) \) follows that:

\[
\begin{align*}
  v_2(4n) &= v_2(n) \\
  v_2(1 + 4n) &= v_2(1) = 0 \\
  v_2(2 + 4n) &= v_2(2) = 1 \\
  v_2(3 + 4n) &= v_2(3) = 0
\end{align*}
\]

In particular:

\[
\begin{align*}
  k_2^2(0) &= 0100 \\
  k_2^2(1) &= 0101
\end{align*}
\]

Compute \( k_2^{m+1}(0) \) by using the induction hypothesis and expanding the substitution. The final step follows from the relations \( v_2(n) = v_2(4n) \) etc. as above.

\[
\begin{align*}
  k_2^{m+1}(0) &= k_2^2(k_2^{m-1}(0)) \\
  &= k_2^2(v_2(1), \ldots, v_2(2^{m-1})) \\
  &= 0, 1, 0, v_2(1), \ldots, 0, 1, 0, v_2(2^{m-1}) \\
  &= v_2(1), v_2(2), v_2(3), v_2(4), \ldots, v_2(2^{m+1} - 3), v_2(2^{m+1} - 2), v_2(2^{m+1} - 1), v_2(2^{m+1})
\end{align*}
\]

The here mentioned constructions of the Thue-Morse and the period doubling word have long been known in literature. A first generalization of the period doubling word was given by [JK69], who used a construction originally conceived by O. Toeplitz. The period doubling morphism can be generalized in two ways. The first way generalizes \( v_2 \) to \( v_p \) with \( p \) a prime. It is described at the end of this section and also in Appendix A. The second generalization gives rise to the rotated Toeplitz substitutions and I think this is a new result.

For starters, define the rotated substitution:

**Definition 3.5 (rotated substitution).** Let \( h \) be a prolongable substitution over alphabet \( \Sigma \). For all \( c \in \Sigma, m \in \mathbb{N} \) there is \( n \in \mathbb{N} \) and \( d \in \Sigma^* \) so that

\[
h^m(c) = d = d_0 d_1 \ldots d_n
\]

The rotated substitution \( \rho_{i,h^m} \) is a substitution created by taking substitution \( h^m \) and rotating it by \( i \):

\[
\begin{align*}
  \rho_{1,h^m}(c) &= d_n d_0 \ldots d_{n-1} \\
  \rho_{i,h^m}(c) &= d_{n-i+1} \ldots d_n d_0 \ldots d_{n-i}
\end{align*}
\]

For example:

\[
\begin{align*}
  k_3(0) &= 01000101 \\
  k_3(1) &= 01000100 \\
  \rho_{1,k^3}(0) &= 10100010 \\
  \rho_{1,k^3}(1) &= 00100010 \\
  \rho_{2,k^3}(0) &= 01010001 \\
  \rho_{2,k^3}(1) &= 00010001
\end{align*}
\]

It should be stressed that \( \rho_{2,k^3} \) is a substitution in its own right as opposed to being an operator on another substitution.

\[\text{The mixed generalization, the rotated Toeplitz substitution for } p \text{ prime, is also covered in Appendix A.}\]
A theorem that shows a relation between the fixed point of a rotated Toeplitz substitution and the $v_2$ function can now be stated.

**Lemma 3.6.** Then for any non-zero integer $a$ such that $-2^m < a < 2^m$ and $n \in \mathbb{N}_{>0}$ it holds that:

$$v_2(n2^m + a) = v_2(n2^m - a) = v_2(a)$$

**Proof.** Immediate. $\square$

**Lemma 3.7.** Let $k$ denote the Toeplitz substitution over the $\{0, 1\}$ alphabet. Let $0 < a < 2^m - 1$ with $a, m \in \mathbb{N}_{>0}$ fixed. Then

$$\rho_{a+1,k}^\infty(v_2(a)) = \{v_2(a + n(2^m - 1))\}^{n \in \mathbb{N}}$$

**Proof.** First it is shown that the first $2^m$ symbols of both sides match. Secondly a recurrence relation will be proven to hold for both sides. Together with the first step this completes the proof.

Note that $\rho_{a+1,k}^\infty$ is a substitution prolongable on $v_2(a)$. The following holds:

$$\begin{align*}
k^m(0) &= v_2(1), v_2(2), \ldots, v_2(2^m) \\
k^m(1) &= v_2(2^m + 1), v_2(2^m + 2), \ldots, v_2(2^{m+1})
\end{align*}$$

It follows from lemma 3.6:

$$\begin{align*}
k^m(0) &= v_2(1), v_2(2), \ldots, v_2(2^m - 1), v_2(2^m) \\
k^m(1) &= v_2(2^m + 1), v_2(2^m + 2), \ldots, v_2(2^{m+1} - 1), v_2(2^{m+1}) \\
&= v_2(1), v_2(2), \ldots, v_2(2^m - 1), v_2(2^m) \\
k^m(v_2(a)) &= v_2(1), v_2(2), \ldots, v_2(2^m - 1), v_2(a2^m)
\end{align*}$$

Note that $k^m(v_2(a))$ only depends on $a$ in the $2^m$-th (final) entry. It is important for the second step of the proof to see that if $m$ is even it holds $v_2(a2^m) = v_2(a)$ and likewise when $m$ odd $v_2(a2^m) = 1 - v_2(a)$. Rotate $k^m(v_2(a))$ to obtain $\rho_{a+1,k}^\infty(v_2(a))$ and use lemma 3.6 to rewrite:

$$\begin{align*}
\rho_{a+1,k}^\infty(v_2(a)) &= v_2(2^m - a), \ldots, v_2(a2^m), v_2(1), \ldots, v_2(2^m - a - 1) \\
&= v_2(a), \ldots, v_2(a + (a2^m - 1)), v_2(a + (a)(2^m - 1)), \ldots, v_2(a + (2^m - 1)(2^m - 1))
\end{align*}$$

This completes the first step of the proof. Suppose $m$ is even. Let $0 \leq c < 2^m - 1$ with $c \neq a$ and substitute $n = c + r2^m$ for $r \in \mathbb{N}$, then it follows by lemma 3.6 that:

$$\begin{align*}
v_2(a + (2^m - 1)n) &= v_2(a + (2^m - 1)(c + r2^m)) \\
&= v_2(a + c(2^m - 1) + (2^m - 1)r2^m) \\
&= v_2(a + c(2^m - 1))
\end{align*}$$

Which shows that for $c \neq a$, the $c + 2^m r$-th entry is actually equal to the $c$-th entry of the sequence. Now suppose $m$ is even and $c = a$:

$$\begin{align*}
v_2(a + (2^m - 1)n) &= v_2(a + (2^m - 1)(c + r2^m)) \\
&= v_2(a + (2^m - 1)(a + r2^m)) \\
&= v_2(2^m(a + (2^m - 1)r)) \\
&= v_2(a + (2^m - 1)r)
\end{align*}$$

So for $c = a$, the $a + 2^m r$-th entry of $\{v_2(a + n(2^m - 1))\}^{n \in \mathbb{N}}$ is actually equal to the $r$-th entry of the sequence. Using $m$ even the rotated substitution is given by:

$$\begin{align*}
\rho_{a+1,k}^\infty(0) &= v_2(2^m - a), \ldots, v_2(2^m - 1), 0, v_2(1), \ldots, v_2(2^m - a - 1) \\
\rho_{a+1,k}^\infty(1) &= v_2(2^m - a), \ldots, v_2(2^m - 1), 1, v_2(1), \ldots, v_2(2^m - a - 1)
\end{align*}$$
Conclude that indeed the $r$-th entry of the fixed point of the substitution is equal to its $a + 2^nr$-th entry. Both sequences have the same recurrence rules when $m$ is even. Now consider $m$ odd. As before with $c \neq a$:

$$v_2(a + (2^n - 1)n) = v_2(a + c(2^m - 1))$$

However for $c = a$ it follows:

$$v_2(a + (2^n - 1)n) = v_2(a + (2^m - 1)(a + r2^m)) = v_2(2^m(a + (2^m - 1)r)) = 1 - v_2(a + (2^m - 1)r)$$

For $m$ odd the rotated substitution is given by:

$$\rho_{a+1,km}(0) = v_2(2^m - a), \ldots, v_2(2^m - 1), 1, v_2(1), \ldots, v_2(2^m - a - 1)$$

$$\rho_{a+1,km}(1) = v_2(2^m - a), \ldots, v_2(2^m - 1), 0, v_2(1), \ldots, v_2(2^m - a - 1)$$

The result follows. □

**Theorem 3.8.** Let $a, b \in \mathbb{N}_{>0}$ such that $0 < a < b$ and $b$ odd. Then there are some $c, m \in \mathbb{N}_{>0}$ such that

$$\{v_p(a + bn)\}_{n \in \mathbb{N}} = \lim_{n \to \infty} \rho_{ac+1,km}^n(v_p(ac))$$

**Proof.** Suppose $c, m$ are such that $cb = 2^m - 1$. Then $c$ is odd and by lemma 3.7 write:

$$\{v_2(a + bn)\}_{n \in \mathbb{N}} = \{v_2(ca + cbn)\}_{n \in \mathbb{N}}$$

So now we show that there are some $c, m$ such that $cb = 2^m - 1$. Suppose that $b \nmid 2^m - 1$ for all $m \in \mathbb{N}_{>0}$. Then by the pigeon hole principle there must be some $r, s, v \in \mathbb{N}_{>0}$ such that

$$2^r - 1 \equiv v \mod b$$

$$2^{r+s} - 1 \equiv v \mod b$$

It follows that:

$$b \mid 2^{r+s} - 2^r$$

$$b \mid 2^r(2^s - 1)$$

$$b \mid 2^s - 1$$

So then $b$ does divide $2^s - 1$, which is a contradiction. □

There is an obvious generalization to Theorem 3.8. Define for $p$ a prime:

$$k_p(0) = 0^{p-1}1$$

$$k_p(1) = 0^{p-1}0$$

$$v_p(n) = \{\max_b p^b | n\} \mod 2$$

Then it follows in a very similar way that

$$\{v_p(n)\}_{n \in \mathbb{N}_{>0}} = k_p^\infty(0)$$

Equally, if $a, b \in \mathbb{N}_{>0}$ are such that $0 < a < b$ and $p \nmid b$, then there are some $c, m \in \mathbb{N}_{>0}$ such that

$$\{v_p(a + bn)\}_{n \in \mathbb{N}} = \rho_{ac+1,km}^\infty(v_p(ac))$$
The proof can be found in appendix A, and has the same structure as the non-generalized version. As a corollary to theorem 3.8 and the deep results of [Mah29] and [Dek77] we find

**Corollary 3.9.** Let \( a, b \in \mathbb{N}_{>0} \) such that \( 0 < a < b \), \( p \nmid b \) and \( p \) a prime. Then
\[
\xi = \sum_{n=0}^{\infty} v_p(a + bn)p^{-n} \text{ is a transcendental number.}
\]

**Proof.** This is a direct result by applying theorem A.5 and theorem 13.5.4 from p.393 [AS03].

## 4. On p-adic rationals

Consider the non-zero rational numbers of the 2-adic numbering system. Without loss of generality, such a rational number can be written as

\[
\frac{q}{2^m - 1}
\]

for some \( q \in \mathbb{Z} \setminus \{0\} \) and \( m \in \mathbb{N}_{>0} \). Every non-zero rational can be associated with a Toeplitz stream in the following fashion:

\[
\{v_2\left(\frac{q}{2^m - 1} + n\right)\}^{n \in \mathbb{N}} := \{v_2(q + n(2^m - 1))\}^{n \in \mathbb{N}}
\]

For example, the number 1 is associated with the period doubling sequence:

\[
\{v_2(1 + n)\}^{n \in \mathbb{N}} = \{v_2(n)\}^{n \in \mathbb{N}_{>0}}
\]

The 2-adic rational \( \frac{1}{2} \) is associated with the following arithmetic subsequence of the period doubling sequence:

\[
\{v_2\left(\frac{1}{3} + n\right)\}^{n \in \mathbb{N}} = \{v_2(1 + 3n)\}^{n \in \mathbb{N}}
\]

It follows from section 3 that \( \{v_2\left(\frac{1}{3} + n\right)\}^{n \in \mathbb{N}} \) is the fixed point of the substitution \( \rho_{2,k} \). For \( 0 < q < (2^m - 1) \) it holds that \( \{v_2(\frac{q}{2^m - 1} + n)\}^{n \in \mathbb{N}} \) is the fixed point of \( \rho_{q+1,k^m} \) as proved in theorem 3.7. What happens if \( \rho_{q+1,k^m} \) is applied once to an arbitrarily arithmetic subsequence of \( v_2 \)? It turns out that:

\[
\rho_{q+1,k^m}\left(\{v_2\left(\frac{r}{2^m - 1} + n\right)\}^{n \in \mathbb{N}}\right) = \{v_2\left(\frac{2^mr}{2^m - 1} - q + n\right)\}^{n \in \mathbb{N}}
\]

Note that applying \( \rho_{q+1,k^m} \) to the fixed point \( \rho_{q+1,k^m}^\infty \) yields again the fixed point. The following theorem summarizes and extends the discussion up to this point.

**Theorem 4.1.** Let \( \rho_{q+1,k^m} \) be a rotated Toeplitz substitution as noted in section 3 with \( 0 < q < (2^m - 1) \) and \( m \in \mathbb{N}_{>0} \). Then for every \( r \in \mathbb{Z} \setminus \{0\} \) and \( l \in \mathbb{N}_{>0} \) it holds

\[
\rho_{q+1,k^m}\left(\{v_2\left(\frac{r}{2^m - 1} + n\right)\}^{n \in \mathbb{N}}\right) = \{v_2\left(\frac{2^mr}{2^m - 1} - q + n\right)\}^{n \in \mathbb{N}}
\]

**Proof.** It will be shown that both sides of the equation have the same recurrence rules. From the recurrence rules follows that the first \( 2^m \) letters of both sides are the same, completing the proof. But first recall from section 3 the construction of the rotated substitution \( \rho_{q+1,k^m} \):

\[
k^m(0) = v_2(1), v_2(2), v_2(3), \ldots, v_2(2^m - 1), v_2(2^m) \]
\[
k^m(1) = v_2(1), v_2(2), v_2(3), \ldots, v_2(2^m - 1), 1 - v_2(2^m)
\]
\[
\rho_{q+1,k^m}(0) = v_2(2^m - q), v_2(2^m - q + 1), \ldots, v_2(2^m), v_2(1), \ldots, v_2(2^m - q - 1)
\]
\[
\rho_{q+1,k^m}(1) = v_2(2^m - q), v_2(2^m - q + 1), \ldots, 1 - v_2(2^m), v_2(1), \ldots, v_2(2^m - q - 1)
\]
Suppose \( m \) is even and consider \( n = q + i2^m \) with \( i \in \mathbb{N} \). It holds:

\[
v_2\left(\frac{2^m r}{2^i - 1} - q + n\right) = v_2\left(\frac{2^m r}{2^i - 1} - q + q + i2^m\right) \\
= v_2(2^m(r + i(2^i - 1))) \\
= v_2(r + i(2^i - 1)) \\
= v_2(\frac{r}{2^i - 1} + i)
\]

Now consider the left hand side of the statement and denote

\[
\rho_{q+1,k} = (v_2\left(\frac{r}{2^i - 1} + i\right)) = \rho_0, \rho_1, \ldots, \rho_{2^m - 1}
\]

then \( \rho_q = v_2\left(\frac{r}{2^i - 1} + i\right) \). Now if \( m \) were odd, then \( \rho_q = 1 - v_2\left(\frac{r}{2^i - 1} + i\right) \) and:

\[
v_2\left(\frac{2^m r}{2^i - 1} - q + n\right) = 1 - v_2\left(\frac{r}{2^i - 1} + i\right)
\]

So for \( n = q + i2^m \) with \( i \in \mathbb{N} \) the equation-to-prove holds. Now consider \( n = s + i2^m \) with \( s \neq q \) and \( 0 \leq s < 2^m \). It follows that \( |s - q| < 2^m - 1 \), which is to be used in the second to final step of the derivation below:

\[
v_2\left(\frac{2^m r}{2^i - 1} - q + n\right) = v_2\left(\frac{2^m r}{2^i - 1} - q + s + i2^m\right) \\
= v_2(2^m(r + (2^i - 1)(s - q + i2^m))) \\
= v_2(2^m(r + (2^i - 1)i) + (2^i - 1)(s - q)) \\
= v_2(|s - q|)
\]

It is clear that for \( n = s + i2^m \) with \( s \neq q \) and \( 0 \leq s < 2^m \) the expression is dependent on \( s \) and independent of \( i \). In fact, the expansion of \( \rho_{q+1,k} \) given at the start of the proof now shows the two sides are equal. □

5. On Automata

**Definition 5.1.** An automaton (also called a deterministic finite automaton with output (DFAO) by [AS03]) is a sextuple \( A = (Q, \Sigma, \delta, q_0, \Delta, \tau) \) where

- \( Q \) is a finite set of states
- \( \Sigma \) is a finite set, the input alphabet
- \( \delta \subseteq Q \times \Sigma \times Q \) is a transition function
- \( q_0 \in Q \) is the initial state
- \( \Delta \) is a finite set, the output alphabet
- \( \tau : Q \to \Delta \) is the output function

Assume the transition relation to be deterministic: For all \( q \in Q, a \in \Sigma \) there exists a unique \( q' \in Q \) such that

\[
\delta(q, a) = q'
\]

Also assume the output function to be deterministic: For all \( q \in Q \), there is a unique \( d \in \Delta \) such that

\[
\tau(q) = d
\]

Suppose \( q, q' \in Q, a \in \Sigma \). Then

\[
\delta(q, a) = q'
\]

describes the edge from state \( q \) to state \( q' \) that takes input \( a \). The automaton starts in the initial state and receives a word as input. The symbols of the word are processed one at a time, such that the state of the machine shifts according to the \( \delta \) function. For instance, let the word 101 be used as input for the automaton depicted in Figure 2. The sequence of the traversed states starts with initial state
Let \( q_0 \) and subsequent states visited would be \( q_1, q_1, q_0 \). Because \( \tau(q_0) = 0 \), the output would be 0. This is denoted by \( A(101) = 0 \).

**Definition 5.2.** Let \( s_k(n) \) be the expansion of integer \( n \) in base \( k \) with the most significant digit first. A sequence \( \{a_n\}_{n \in \mathbb{N}} \) is called a \( k \)-automatic sequence if there is some automaton \( A \) such that for all \( n \in \mathbb{N} \) we have \( a_n = A(s_k(n)) \).

Using the automaton from Figure 2, the Thue-Morse sequence may be constructed. So the Thue-Morse sequence is an \( 2 \)-automatic sequence. The automaton generating the Toeplitz word is depicted in Figure 3. It is known that if instead \( s_k(n) \) would start with the least significant digit first, this would not change the class of automatic sequences [AS03].

**Theorem 5.3 (Cobham).** Let \( k \geq 2 \). Then a sequence \( u \) is \( k \)-automatic if and only if it is the image, under a \( 1 \)-uniform substitution, of a fixed point of a \( k \)-uniform substitution.

**Proof.** Proof using the same construction as [AS03], p 175.

\( \Rightarrow \) Suppose \( u = \tau(w) \) with \( \tau: \Sigma \to \Sigma' \) a coding and \( w = w_0 w_1 \ldots \) a fixed point of a \( k \)-uniform morphism \( h: \Sigma^+ \to \Sigma^* \). Let \( s_k(n) \) be as before. The claim is that some automaton \( A = (Q, \Sigma, \delta, q_0, \Sigma', \tau) \) exists such that:

\[ A(s_k(n)) = \tau(w_n) = u_n \]

Let \( q_0 = w_0 \) and let \( Q = \Sigma \). Define the transition function for every \( q \in \Sigma \) and \( 0 \leq b < k \):

\[ \delta(q, b) = \text{the } b\text{-th letter of } h(q) \]

Use induction on the length \( |s_k(n)| \). For \( |s_k(n)| = 0 \) the claim holds because \( q_0 = w_0 \). Suppose the claim holds for \( |s_k(n)| = i \), then it will be shown to hold for \( |s_k(n)| = i + 1 \). Denote for some \( n \) the base-\( k \) expansion \( s_k(n) = s_0 s_1 \ldots s_{i+1} \). In
particular, \( n = kn' + s_{i+1} \) where \( s_k(n') = s_0s_1 \ldots s_i \). By the induction step it holds that

\[
\delta(q_0, s_0s_1 \ldots s_i) = w_{n'}
\]

Because \( h \) is \( k \)-uniform, it holds that \( w_n \) is the \( s_{i+1} \)-th letter of \( h(w_{n'}) \). Then there follows:

\[
\begin{align*}
A(s_k(n)) &= \tau(\delta(q_0, s_k(n))) \\
&= \tau(\delta(q_0, s_0s_1 \ldots s_{i+1})) \\
&= \tau(\delta(q_0, s_0s_1 \ldots s_i, s_{i+1})) \\
&= \tau(\delta(w_{n'}, s_{i+1})) \\
&= \tau(\text{the } s_{i+1} \text{-th symbol of } h(w_{n'})) \\
&= v_n
\end{align*}
\]

⇒ Assume that \( u \) is a \( k \)-automatic sequence, so that \( u_n = \tau(w_n) = \tau(\delta(q_0, s_k(n))) \) for some automaton \( A = (Q, \Sigma_k, \delta, q_0, \Sigma', \tau) \). Assume \( \delta(q_0, 0) = q_0 \). Define the morphism \( h : Q^+ \to Q^+ \) in the following fashion:

\[
h(q) = \delta(q, 0)\delta(q, 1) \ldots \delta(q, k - 1)
\]

Then morphisms \( h \) is prolongable on \( q_0 \) with some fixed point \( w' \). Then it is clear that \( w'_n = \delta(q_0, s_k(n)) \) holds for \( |s_k(n)| \leq 1 \). Assume \( w'_n = \delta(q_0, s_k(n)) \) holds for \( |s_k(n)| \leq i \). Then showing it also holds for \( |s_k(n)| \leq i + 1 \) completes the proof. Denote for some \( n \) the base-\( k \) expansion \( s_k(n) = s_0s_1 \ldots s_{i+1} \). In particular there holds \( n = kn' + s_{i+1} \) where \( s_k(n') = s_0s_1 \ldots s_i \). So it follows:

\[
\begin{align*}
\delta(q_0, s_k(n)) &= \delta(q_0, s_0s_1 \ldots s_{i+1}) \\
&= \delta(w'_{n'}, s_{i+1}(n)) \\
&= \text{the } s_{i+1} \text{-th letter of } h(w'_{n'}) \\
&= w_{kn'+s_{i+1}} \\
&= w_n
\end{align*}
\]

\[\square\]

**Theorem 5.4.** Let \( h \) be a \( k \)-uniform substitution over alphabet \( \Sigma_r = \{0, 1, \ldots, r - 1\} \) prolongable on \( 0 \). Denote

\[
\begin{align*}
h^\infty(0) &= w \\
&= w_0w_1w_2 \ldots
\end{align*}
\]

Then for any \( a, b \in \mathbb{N} \) \( \{w_{a+b_n}\}^n_{n \in \mathbb{N}} \) is a \( k \)-automatic sequence.

**Proof.** This is a direct result from the definition of automatic sequences and lemma 6.6. An alternative using Cobham's theorem is:

Let \( \Sigma_r^b = \{0, 1, \ldots, r - 1\}^b \) be an alphabet consisting of all words of length \( b \) over \( \Sigma_r \). Construct the substitution \( h^* : \{\Sigma_r^b\}^+ \to \{\Sigma_r^b\}^+ \) of uniform length \( k \) in the following fashion: Let \( d \in \Sigma_r^b \), then

\[
h^*(d) = h(d)
\]

Then \( h^* \) is prolongable on \( w_0w_1 \ldots w_{b-1} \in \Sigma_r^b \) with fixed point \( w \). Let the 1-uniform substitution (coding) \( c : \Sigma_r^b \to \{0, 1, \ldots, r\} \) be:

\[
c(d) = \{ \text{the } a \text{-th letter of } d \}
\]

Then applying the coding to \( w \) indeed yields \( \{w_{a+b_n}\}^n_{n \in \mathbb{N}} \). \[\square\]
An example of the above theorem is given: The 2-uniform prolongable substitution that has as fixed point \( \{ TM(1 + 3n) \}^\infty \) is given by:

\[
\begin{align*}
g^*(A) &= AB \\
g^*(B) &= AC \\
g^*(C) &= BD \\
g^*(D) &= EC \\
g^*(E) &= FD \\
g^*(F) &= FE \\
c(A) &= 1, \quad c(B) = 1, \quad c(C) = 0 \\
c(D) &= 1, \quad c(E) = 0, \quad c(F) = 0 \\
g^\infty(A) &= ABACABBDABACACEC \ldots \\
TM(1 + 3n) &= 111011111101000 \ldots
\end{align*}
\]  

The above substitution can be derived by expanding the Thue-Morse word in blocks of three digits: The 2-uniform substitution for Thue-Morse is:

\[
\begin{align*}
g(0) &= 01 \\
g(1) &= 10
\end{align*}
\]  

From this the substitution \( g^*() \) over the alphabet of words of length 3 and coding \( c() \) follows:

\[
\begin{align*}
g^*(011) &= 011 \, 010 \\
g^*(010) &= 011 \, 001 \\
g^*(001) &= 010 \, 110 \\
g^*(110) &= 101 \, 001 \\
g^*(101) &= 100 \, 110 \\
g^*(100) &= 100 \, 101 \\
c(011) &= 1, \quad c(010) = 1, \quad c(001) = 0 \\
c(110) &= 1, \quad c(101) = 0, \quad c(100) = 0
\end{align*}
\]  

Substitution \( g^* \) is prolongable on \( 011 \) and has fixed point \( TM \):

\[
\begin{align*}
TM : & \quad 011 \, 010 \, 011 \, 001 \, 011 \, 010 \, 110 \, 011 \, 010 \, 110 \, 011 \, 001 \, 001 \, 101 \, 001 \ldots \\
TM(1 + 3n) : & \quad 1 \, 1 \, 1 \, 0 \, 1 \, 1 \, 1 \, 1 \, 1 \, 1 \, 1 \, 1 \, 1 \, 0 \, 1 \, 0 \, 0 \, 1 \, 1 \ldots
\end{align*}
\]  

6. On transducers

**Definition 6.1.** A finite state transducer (which will be abbreviated to FST or transducer) is a sextuple \( T = (Q, \Sigma, \delta, q_0, \Delta, \lambda) \) where

\begin{itemize}
  \item \( Q \) is a finite set of states
  \item \( \Sigma \) is a finite set, the input alphabet
  \item \( \delta \subseteq Q \times \Sigma \times \Delta^* \times Q \) is a transition relation
  \item \( q_0 \in Q \) is the initial state
  \item \( \Delta \) is a finite set, the output alphabet
  \item \( \lambda : Q \times \Sigma \rightarrow \Delta^* \) is the output function
\end{itemize}

Suppose \( q_1, q_2 \in Q, a \in \Sigma, b \in \Delta^* \) then \((q_1, a, b, q_2) \in \delta\)
Proof. Let \( \text{Lemma 6.3.} \)

\[ (q_1, a, b, q_2) \in \delta \]

Now define the \textit{extended transition relation} \( \delta^* \subseteq Q \times \Delta^* \times \Gamma^* \times Q \) to be the closure of \( \delta \):

- \( \delta \subseteq \delta^* \)
- \( (q, \epsilon, \epsilon, q) \in \delta^* \) for all \( q \in Q \)
- If \( (q_1, a, b, q_2) \in \delta^* \) and \( (q_2, c, d, q_3) \in \delta \) then \( (q_1, ac, bd, q_3) \in \delta^* \).

Then it is clear that \( \delta^* \) contains all the possible paths on the graph of \( \Lambda \). Also define the \textit{transition function} \( \delta : Q \times \Sigma \to Q \) and the \textit{output function} \( \lambda : Q \times \Sigma \to \Delta^* \):

\[ \delta(q_1, a) = q_2 \text{ and } \lambda(q_1, a) = b \text{ if and only if } (q_1, a, b, q_2) \in \delta^* \]

It should be clear from the notation that \( \delta(\cdot) \) denotes the function and \( \delta, \delta^* \) the sets. For transducer \( T \) note that \( T(a) = b \) if \( \lambda(q_0, a) = b \).

Let \( L \) be a language. Then

\[ T(L) = \{ T(a) \mid a \in L \} \]
\[ T^{-1}(L) = \{ a \in \Sigma^* \mid T(a) \in L \} \]

**Lemma 6.2.** There are countably many finite state transducers.

**Proof.** The transducer is entirely determined by the transition relation \( \delta \). In other notation, denote

\[ F : Q \times \Sigma \times Q \to \Delta^* \]

such that \( F(q_1, a, q_2) = b \) if and only if:

\[ (q_1, a, b, q_2) \in \delta \]

Then the number of such functions \( F \) is countable. \( \square \)

**Lemma 6.3.** Let \( a, b \in \Sigma^+ \) and \( T \) a finite state transducer. Then \( T(a) \) is a prefix of \( T(ab) \).

**Proof.** By the deterministic property it follows that the path defined by input \( ab \) on \( T \) is unique: There is no other path on \( T \) that takes input \( ab \). Then it should be clear that \( T(a) \) is a prefix of \( T(ab) \). \( \square \)

**Definition 6.4.** Denote \( a, b \in \Sigma^\infty \) and \( T \) a finite state transducer. Denote \( T(a) = b \) if and only if for every prefix \( b' \) of \( b \) there is a prefix \( a' \) of \( a \) such that \( b' \) is a prefix of \( T(a') \).

**Lemma 6.5.** Suppose \( T \) is a transducer with output language \( \Sigma' \) and \( R \) a transducer with input language \( \Sigma' \), and let \( w \subseteq \Sigma^* \) be a word. Then there exists a transducer \( T' \) such that \( R(T(w)) = T'(w) \).

**Proof.** Let

\[ T = (Q, q_0, \Sigma, \Sigma', \delta, \lambda) \]
\[ R = (Q', q_0', \Sigma', \Sigma'', \delta', \lambda') \]
\[ T' = (Q'', q_0'', \Sigma, \Sigma'', \delta'', \lambda'') \]

with \( Q'' = Q \times Q' \) and \( q_0'' = [q_0, q_0'] \). Define for all \( a \in \Sigma, [q, q'] \in Q'':\)

\[ ([q, q'], a, \lambda'(q', a), [\delta(q, a), \delta(q', \lambda(a))] \in \delta'' \]

This shows \( T' \) is a properly defined deterministic FST. Take \( a \in \Sigma \) and note that:

\[ R(T(a)) = R(\lambda(q_0, a)) = \lambda'(q_0', \lambda(q_0, a)) = T'(a) \]
By induction on the length of \( w \) it can be shown that for all \( w \in \Sigma^* \) it holds \( R(T(w)) = T'(w) \). \( \square \)

The construction used in the proof of lemma 6.5 is called \textit{wreath product} in [AS03].

**Lemma 6.6.** Let \( T \) be a FST with input and output language \( \Sigma_k = \{0, 1, \ldots, k-1\} \). Let \( A \) be an automaton with input language \( \Sigma_k \). Then there is an automaton \( A' \) such that for all \( w \in \Sigma_k^* \) it holds that \( A(T(w)) = A'(w) \).

**Proof.** The idea here is to create a automaton \( A' \) that has state space \( Q \times Q' \) and emulates the path of both \( T \) and \( A \) at the same time. Let 
\[
T = (Q, \Sigma_k, \delta, q_0, \Sigma_k, \lambda) \\
A = (Q', \Sigma_k, \delta', q_0', \Delta, \tau) \\
A' = (Q \times Q', \Sigma_k, \delta'', [q_0, q_0'], \delta'', \tau')
\]
be an automaton such that for all \( a \in \Sigma_k \) and \([q, q'] \in Q \times Q'\) we have
\[
\tau'([q, q'], a, [\delta'(a), \delta''(T(a))] = \tau(\delta''(q'))
\]
On input \( w \) the automaton \( A' \) emulates the FST \( T \) and automaton \( A \) simultaneously:
\[
A'(w) = \tau'([q_0, q_0'], T(w)) = \tau(\delta''(q_0', T(w))) = A(T(w))
\]
\( \square \)

7. **Equivalence of sequences under transducers**

**Definition 7.1.** Let \( a, b \) be streams. Then 
\[
a \triangleright b
\]
if there exists a transducer such that \( A(a) = b \). Clearly, this defines a partial ordering. Denote 
\[
a \mathbin{\circ} b
\]
if and only if \( a \triangleright b \) and \( b \triangleright a \).

**Lemma 7.2.** (Transitivity). Let \( a, b, c \in \Sigma^\infty \) and suppose \( a \triangleright b \), \( b \triangleright c \). Then \( a \triangleright c \). Alternatively, suppose \( a \circ b \), \( b \circ c \). Then \( a \circ c \).

**Proof.** Follows from lemma 6.5 \( \square \)

**Lemma 7.3.** \( \circ \) defines an equivalence relation.

**Proof.** By using the identity transducer for any stream \( a \) there holds \( a \circ a \), so reflexivity is satisfied. Symmetry is also satisfied: for any streams \( a, b \) by definition \( a \circ b \) implies \( b \triangleright a \) and \( a \triangleright b \). By the previous lemma there is also transitivity. \( \square \)

**Theorem 7.4.** There is an uncountable number of degrees of streams.

**Proof.** There are uncountable many infinite sequences over \( \{0, 1\} \). There are countably many transducers. Therefore, the number of degrees is uncountable. \( \square \)

**Lemma 7.5.** Let \( a \in \Sigma^\infty \) and let \( \sigma \) be the shift operator: If \( a = a_0a_1a_2 \ldots \) then \( \sigma a = a_1a_2a_3 \ldots \). For all \( n \in \mathbb{N} \) there holds: 
\[
\sigma^n a \circ a
\]
Proof. \( \triangleright \) For some \( w \in \Sigma^n \) we have that \( a = w \sigma^n a \). Build a transducer such the output for the first letter is \( w \) followed by the letter itself. For every subsequent letter read as input, the transducer outputs the same letter. \( \triangleleft \) We may build an transducer that outputs \( \epsilon \) for the first \( n \) symbols read. For every subsequent letter read as input, the transducer outputs the same letter. □

Lemma 7.6. Let \( a, b \in \{0,1,\ldots,k\}^\infty \) be streams, with \( b \) purely periodic. Let \( c = \{a_n + b_n \mod k\}_{n \in \mathbb{N}} \). Then

\[ a \diamond c \]

Proof. Let the period of \( b \) be \( p \in \mathbb{N}_{>0} \). Then a transducer with exactly \( p \) states can be constructed such that the value of \( a_n + b_n \mod k \) is computed correctly. In particular for \( 0 \leq i < p \) and \( j \in \{0,1,\ldots,k-1\} \):

\[
T = (Q,\{0,1,\ldots,k-1\},\delta,q_0,\{0,1,\ldots,k-1\},\lambda)
\]

\[
Q = \{q_0,q_1,\ldots,q_{p-1}\}
\]

\[
(q_i,j,b_i+j \mod k,q_{i+1}) \in \delta
\]

\[
(q_{p-1},j,b_{p-1}+j \mod k,q_0) \in \delta
\]

This shows that \( T(a) = c \). In a similar fashion a transducer \( R \) can be constructed such that \( R(c) = a \). □

Some examples of transducers now follow. Figure 4 and 5 show that \( TM \circ v_2 \).

\[
\begin{align*}
1 | \epsilon & \quad 1 | 1 & \quad 1 | 0 \\
q_0 & \quad q_1 & \quad q_2
\end{align*}
\]

\( q_0 \) \quad \( q_1 \) \quad \( q_2 \)

\[
\begin{align*}
1 | \epsilon & \quad 0 | \epsilon & \quad 1 | 1 \\
q_0 & \quad q_1 & \quad q_2
\end{align*}
\]

\( q_0 \) \quad \( q_1 \) \quad \( q_2 \)

\textbf{Figure 4.} \( v_2 \triangleright TM \)

\textbf{Figure 5.} \( TM \triangleright v_2 \)

Denote \( \{f_i|f_i \in \mathbb{N}_{>0}\}_{i \in \mathbb{N}_0} \) a positive integer-valued sequence. From Figure 6 and 7 it is clear that:

\[ 1^{f_0}0^{f_1}1^{f_2}0^{f_3}1^{f_4} \ldots \circ 10^{f_0}10^{f_1}10^{f_2}10^{f_3}10^{f_4} \ldots \]
This illustrates that the sequence $f_0 f_1 f_2 \ldots$ is more significant than the words $w_0 w_1 w_2 \ldots$. A transducer can also do simple arithmetic. For example: denote by $f_i \mod 3$ the remainder of $f_i$ after division by 3. Figure 8 shows how an transducer can do this calculation. It is a result first published in [Ste08] that
every subsequence of TM is equivalent to the TM. Recall one of the definitions of
the Thue-Morse sequence:
\[ T_M = \{ \text{number of occurrences of 1 in } s_2(n) \}^{n \in \mathbb{N}} \]

**Theorem 7.7.** Suppose \( a, b \in \mathbb{N}_{>0} \) and \( 0 \leq a < b \). Then:
\[ \{ TM(a + bn) \}^{n \in \mathbb{N}} \circ TM \]

**Proof.** The \( \triangleleft \) implication can be shown by a transducer that outputs every \( b \)th input, and omits everything else. The \( \triangleright \) implication can be shown using another transducer. First note that the Thue-Morse sequence is the fixed point of substitution \( g \):
\[ g(0) = 01 \]
\[ g(1) = 10 \]
It is also the fixed point of \( g^m \) for any \( m \in \mathbb{N}_{>0} \). Note that \( g^m(0) \) is the conjugate of \( g^m(1) \):
\[ g^m(0) = \overline{g^m(1)} \]

The Thue-Morse sequence may be written in the following fashion:
\[ TM = g^m(TM(0))g^m(TM(1))g^m(TM(2)) \ldots \]
In other words, the Thue-Morse word is a concatenation of the words \( g^m(0) \) and \( g^m(1) \). Suppose there is a mystery word \( x \) that can either be \( g^m(0) \) or \( g^m(1) \). Suppose the \( q \)th letter of mystery word \( x \) is known. Then the mystery word \( x \) is known: Because \( g^m(0) = \overline{g^m(1)} \), there is only one candidate that will have a matching letter in the \( g \)-th position. Choose \( m \) such that there is a letter known for every block of length \( 2^m \). Because \( a + bn \) is periodic modulo \( 2^m \), a finite transducer can be build that reconstructs the Thue-Morse sequence from one of its arithmetic subsequences:

Fix \( m \in \mathbb{N}_{>0} \) to be the smallest \( m \) such that \( b \leq 2^m \). Define
\[ c_n = a + bn \mod 2^m \]
so that \( 0 \leq c_n < 2^m \) for all \( n \in \mathbb{N} \). Then \( \{ c_n \}^{n \in \mathbb{N}} \) is periodic with period \( p \), say. Let the transducer \( T = (Q, \Sigma, \delta, q_0, \Delta, \lambda) \) have \( p \) states: \( q_0, q_1, \ldots, q_{p-1} \). The initial state is \( q_0 \). The transducer reads one letter of input at a time, and then moves to the next state regardless of output. For all \( j \) such that \( c_j \geq c_{j+1} \) define the transition
\[ (q_j, a, x, q_{j+1}) \in \delta \]
\[ x = \begin{cases} 
  g^m(0) & \text{if the } c_j \text{-th letter of } g^m(0) \text{ is equal to } a \\
  g^m(1) & \text{if the } c_j \text{-th letter of } g^m(0) \text{ is not equal to } a 
\end{cases} \]

Now suppose that \( c_j < c_{j+1} \) for some \( j \). Then this would mean that the same block would be outputted twice. So for this case define the transition:
\[ (q_j, a, \epsilon, q_{j+1}) \in \delta \]
Regardless of the input, with period \( p \) the transducer returns to state \( q_0 \). \( \square \)
8. On Toeplitz equivalence classes

The purpose of this section is to investigate the equivalence under transducers of the arithmetic subsequences of the Toeplitz word. In other words, the equivalence of sequences given by \( \{v_2(a + bn)\}_{n \in \mathbb{N}} \) is explored. As a final result the results are generalized to \( \{v_p(a + bn)\}_{n \in \mathbb{N}} \) with \( p \) a prime.

**Lemma 8.1.** Let \( b \in \mathbb{N}_{>0} \). Then
\[
\{v_2(bn)\}_{n \in \mathbb{N}_{>0}} \circ v_2
\]

**Proof.** By the base-2 expansion of \( bn \) it follows that:
\[
\{v_2(bn)\}_{n \in \mathbb{N}_{>0}} = \{v_2(b) + v_2(n) \mod 2\}_{n \in \mathbb{N}_{>0}}
\]
The result follows by lemma 7.6. \( \square \)

**Lemma 8.2.** Let \( a, b \in \mathbb{N}_{>0} \) such that \( 0 < a < b \) with \( a \) odd and \( b \) even. There holds:
\[
\{v_2(a + bn)\}_{n \in \mathbb{N}} = 0^n
\]

**Proof.** For the given \( a, b \) it follows that \( a + bn \) is odd for all \( n \in \mathbb{N} \). \( \square \)

Suppose \( a, b \in \mathbb{N}_{>0} \) such that \( 0 < a < b \) with \( a \) even and \( b \) even. Then there is some \( r \in \mathbb{N}_{>0} \) such that
\[
a = 2^r a^* \quad \quad b = 2^r b^*
\]
with \( a^*, b^* \in \mathbb{N} \) appropriately. There holds:
\[
\{v_2(a + bn)\}_{n \in \mathbb{N}} = \{v_2(2^r a^* + b^* n)\}_{n \in \mathbb{N}}
\]
So there follows \( \{v_2(a + bn)\}_{n \in \mathbb{N}} \circ \{v_2(2^r a^* + b^* n)\}_{n \in \mathbb{N}} \).

**Theorem 8.3.** Let \( a, b \in \mathbb{N}_{>0} \) with \( a > 0 \) and \( b \) odd. It holds:
\[
\{v_2(a + bn)\}_{n \in \mathbb{N}} \circ \{v_2(2a + bn)\}_{n \in \mathbb{N}}
\]

**Proof.** \( \circ : \) The first step below follows from creating a transducer that skips every second letter. The second step follows from the definition of \( v_2 \):
\[
\{v_2(2a + bn)\}_{n \in \mathbb{N}} \circ \{v_2(2a + 2bn)\}_{n \in \mathbb{N}}
\]
\[
\{v_2(a + bn)\}_{n \in \mathbb{N}}
\]
\( \triangleright : \) Because \( b \) is odd, there is some \( c, k \in \mathbb{N} \) such that \( cb = 2^k - 1 \) (see proof of theorem 3.8). It holds:
\[
\{v_2(a + bn)\}_{n \in \mathbb{N}} \triangleright \{v_2(a + cba + bn)\}_{n \in \mathbb{N}}
\]
\[
\{v_2(2^k a + bn)\}_{n \in \mathbb{N}}
\]
\[
\{v_2(2a + bn)\}_{n \in \mathbb{N}}
\]
\( \square \)

**Theorem 8.4.** Let \( a, b \in \mathbb{N}_{>0} \) with \( 0 < a < b \). Let \( p \) be a prime and \( p \nmid b \), then:
\[
\{v_p(a + bn)\}_{n \in \mathbb{N}} \circ \{v_p(pa + bn)\}_{n \in \mathbb{N}}
\]

**Proof.** The proof of theorem 8.3 may be generalized to \( p \) prime in an obvious way. \( \square \)
9. A prime sequence

The goal of this section is to show that
\[ \Pi = 1010^210^310^410^510^6 \ldots \]
is a prime sequence, which is one of the main results by [EHK11]. By theorem 9.7 it holds that for any transducer \( T \)
\[ T(\Pi) = w \prod_{i=0}^{n} \prod_{j=0}^{c_j d_j} \]
where \( w, c_j, d_j \) are transducer-specific words and \( n \) a transducer-specific integer. To show that \( \Pi \) is a prime sequence, it has to be shown that either
\[ w \prod_{i=0}^{\infty} \prod_{j=0}^{c_j d_j} > \Pi \]
or the left-hand side of the above equation is periodic. Lemma 9.9 and lemma 9.10 show that in fact for any transducer \( T \) with non-eventually periodic output
\[ T(\Pi) = w \prod_{i=0}^{\infty} \prod_{j=0}^{c_j d_j} \]
theorem 9.8 can be applied. So \( \Pi \) is indeed prime.

**Definition 9.1.** A sequence \( \{f_i\}_{i \in \mathbb{N}} \) with \( f_i \in \mathbb{N} \) is called periodic if there exists a \( p \in \mathbb{N} \) such that \( \forall i, n \in \mathbb{N} \) it holds \( f_{i+np} = f_i \). A sequence is eventually periodic if some suffix of the sequence is periodic. A sequence \( f \) is said to be periodic modulo every positive integer if \( \{f_i \mod n\}_{i \in \mathbb{N}} \) is periodic for every \( n \in \mathbb{N}_{>0} \).

**Lemma 9.2.** For any \( a, b \in \mathbb{N} \) the sequences \( f = \{a+bi\}_{i \in \mathbb{N}} \) and \( g = \{ab^i\}_{i \in \mathbb{N}} \) are eventually periodic modulo every integer.

*Proof.* Periodicity modulo \( m \) will be demonstrated. Denote:
\[
\begin{align*}
f_0 &= a \\
g(x) &= x + b \mod m \\
f_{i+1} &= g(f_i)
\end{align*}
\]
Then \( f_i \) is just an iteration of map \( G \) on a finite set. There exists an \( I \in \mathbb{N}_{>0} \) and a \( p \in \mathbb{N}_{>0} \) such that \( f_I \equiv f_{I+p} \mod m \). So \( f \) is eventually periodic. The same argument can also be given for \( g \). \( \square \)

It can be shown that \( f \) is purely periodic modulo every integer: Fix \( I > 0 \), then there follows:
\[
\begin{align*}
f_I &\equiv f_{I+p} \mod m \\
f_I - bI &\equiv f_{I+p} - bI \mod m \\
f_0 &\equiv f_p \mod m
\end{align*}
\]
This property is in contrast with \( g \), which is not necessarily purely periodic. A similar argument shows that the Fibonacci sequence is also periodic modulo every positive integer, due to [Wal60]. The problem of classifying all sequences that are periodic modulo every integer has been studied in [DP08, PZ82].

**Definition 9.3 (zero-loop).** For any state \( q_i \in Q \) of a finite state transducer define its zero-loop. The zero-loop is the path traversed when starting in state \( q_i \) and feeding only zeros as input. Because there are only finitely many states, such a path will return to a previously visited state eventually. In other words, the sequence \( \{\delta(q_i, 0^j)\}_{j \in \mathbb{N}} \) is eventually periodic with period \( n \in \mathbb{N} \). Denote the first state to
be visited twice as state \(q\). The sequence \(\{q, \delta(q, 0), \ldots, \delta(q, 0^{m-1})\}\) is the zero-loop belonging to \(q\).

**Lemma 9.4** (Pumping lemma for transducers). Denote \(|Q|\) the number of states in given transducer \(T = (Q, \{0, 1\}, \delta, q_0, \Delta, \lambda)\). Denote \(Z\) the least common multiple of the periods of all zero-loops in \(T\). Let \(\{f_i\}_{i \in \mathbb{N}}\) be a sequence that is periodic modulo \(Z\) with period \(p\) such that for all \(i, j \in \mathbb{N}\) \(f_{i+j} > f_i\). Let there be a \(N \in \mathbb{N}\) such that for all \(m > N\) it holds \(f_m > |Q|\). Then for every \(m\) and \(q \in Q\) there exists another fixed state \(q' \in Q\) and words \(c, d \in \Delta^*\) so that for every \(i \in \mathbb{N}\) holds:

\[
(q, 10^{f_{m+i}}, cd^{ai}, q') \in \delta^n
\]

with

\[
a_i = \frac{f_{m+ip} - f_m}{Z}
\]

**Proof.** Consider the statement-to-prove for \(i = 0\) at first. State \(q\) accepts input \(10^{f_m}\), so there must be \(q' \in Q, c \in \Delta^*\) such that

\[
(q, 10^{f_m}, c, q') \in \delta^n.
\]

By the pigeonhole principle it holds that there must occur a zero-loop for the input \(10^{f_m}\), because \(f_m > |Q|\). The state \(q'\) as defined above must be part of this zero-loop. Then there must be some \(d \in \Delta^*\) such that

\[
(q', 0^2, d, q') \in \delta^n
\]

Then it is clear that

\[
(q, 10^{f_{m+i}}, cd^{ai}, q') \in \delta^n
\]

\(\square\)

**Lemma 9.5.** Denote \(|Q|\) the number of states in given transducer \(T = (Q, \{0, 1\}, \delta, q_0, \Delta, \lambda)\). Let \(Z\) be the least common multiple of the periods of all zero-loops in \(T\). Let \(\{f_i\}_{i \in \mathbb{N}}\) be a sequence that is periodic modulo \(Z\) with period \(p\) such that for all \(i, j \in \mathbb{N}\) \(f_{i+j} \geq f_i\). Let there be an \(N \in \mathbb{N}\) such that for all \(m > N\) it holds \(f_m > |Q|\). Then for every \(m\) and \(q \in Q\) there exists another fixed state \(q' \in Q\) and words \(c, d, d' \in \Delta^*\) so that for all \(i \in \mathbb{N}\)

\[
(q, 10^{f_{m+i+p}} 10^{f_{m+p+1}} \cdots 10^{f_{m+p+(i+1)p}}, \prod_{j=1}^{p} c_j d_j^{ai}, q') \in \delta^n
\]

where

\[
a_{i,j} = \frac{f_{m+j+i} - f_{m+j}}{Z}
\]

**Proof.** Begin by applying lemma 9.4 for state \(q\) and input \(10^{f_{m+i+p+1}}\). We now have

\[
(q, 10^{f_{m+i+p}}, c_1 d_1^{a_{i,1}}, q_1) \in \delta^n
\]

Equally for state \(q_1\) there will be some state \(q_2\) so that there holds:

\[
(q_1, 10^{f_{m+2+p}}, c_2 d_2^{a_{1,2}}, q_2) \in \delta^n
\]

Combining these findings it follows that:

\[
(q, 10^{f_{m+i+p}} 10^{f_{m+2+p}} 10^{f_{m+3+p}}, c_1 d_1^{a_{i,1}} c_2 d_2^{a_{1,2}} c_3 d_3^{a_{1,3}}, q_3) \in \delta^n
\]

Or one more term:

\[
(q, 10^{f_{m+i+p}} 10^{f_{m+2+p}} 10^{f_{m+3+p}}, c_1 d_1^{a_{i,1}} c_2 d_2^{a_{1,2}} c_3 d_3^{a_{1,3}}, q_3) \in \delta^n
\]
Continue all up to 1, 2, 3, . . . , p such that for a certain $q'$ there holds:

$$(q, 10^{f_{m+i+p+1}}10^{f_{m+i+p+2}} \cdots 10^{f_{m+(i+1)p}}, \prod_{j=1}^{p} c_j d_j^{a_{i,j}}, q') \in \delta^*$$

This proves the lemma. □

**Lemma 9.6.** Denote $|Q|$ the number of states in a given transducer $T = (Q, \delta, \Sigma, \Delta, \lambda)$.

Let $Z$ be the least common multiple of the periods of all zero-loops in $T$. Let $\{f_i\}_{i \in \mathbb{N}}$ be a sequence that is eventually periodic modulo $Z$ with period $p$ such that for all $i, j \in \mathbb{N} f_{i+jp} \geq f_i$. Let there be an $N \in \mathbb{N}$ such that for all $m > N$ it holds $f_m > |Q|$ and $\{|f_n|\}_{n \geq m}$ periodic. Then there must be some $m$ and $q \in Q$ with words $w, c_j, d_j \in \Sigma^*$ and $k \in \mathbb{N}_{>0}$ such that there holds for all $i \in \mathbb{N}$

$$(q_0, 10^{f_0}10^{f_1}10^{f_2} \cdots 10^{f_m}, w, q) \in \delta^*$$

such that for all $m \geq 0$

$$(q, 10^{f_{m+i+p}}10^{f_{m+i+p+2}} \cdots 10^{f_{m+(i+1)p}}, \prod_{j=1}^{p} c_j d_j^{a_{i,j}}, q') \in \delta^*$$

Define a function $t : Q \rightarrow Q$ such that $t(q) = q'$ if and only if:

$$(q, 10^{f_{m+i+p}}10^{f_{m+i+p+2}} \cdots 10^{f_{m+(i+1)p}}, \prod_{j=1}^{p} c_j d_j^{a_{i,j}}, q') \in \delta^*$$

Then by Lemma 9.5, $t(q)$ is defined for every $q \in Q$. By the same lemma $t$ is invariant in $i$. Consider the sequence:

$q^* = t(q^*), t^2(q^*), t^3(q^*), t^4(q^*), \ldots$ 

Then let state $q$ denote the first state that reoccurs in the above sequence. This means that there is some $k \in \mathbb{N}$ such that:

$$t^k(q) = q$$

In other words, $q$ is the fixed point of the function $t^k$. There holds:

$$(q, 10^{f_{m+i+p}}10^{f_{m+i+p+2}} \cdots 10^{f_{m+i+10p}}, \prod_{j=1}^{p} c_j d_j^{a_{i,j}}, q) \in \delta^*$$

Denote $r$ to be the smallest integer such that $t^r(q^*) = q$. There holds:

$$(q_0, 10^{f_0}10^{f_1}10^{f_2} \cdots 10^{f+m+p}, w, q) \in \delta^*$$

Renaming the constants completes the proof. □

**Theorem 9.7.** Let $\{f_i\}_{i \in \mathbb{N}}$ be a sequence that is eventually periodic modulo $Z$ with period $p$ such that for all $i, j \in \mathbb{N} f_{i+jp} \geq f_i$. Denote $T = (Q, \Sigma, \delta, q_0, \Delta, \lambda)$ a finite state transducer. Then there are some $k \in \mathbb{N}$ and $w, c_j, d_j \in \Sigma^*$ such that

$$T(\prod_{i=0}^{\infty} 10^{f_i}) = w \prod_{i=0}^{k} \prod_{j=1}^{p} c_j d_j^{a_{i,j}}$$

with

$$a_{i,j} = \frac{f_{m+j+i} - f_{m+j}}{Z}$$
where $\mathbb{Z}$ is the least common multiple of all zero-loops in $T$.

Proof. By lemma 9.6 the theorem holds. \hfill \Box

**Theorem 9.8.** Let $w \prod_{i=0}^{\infty} \prod_{j=0}^{n} c_j d_i^j$ be a non-eventually periodic word for $n \geq 1$ and some $w, c_j, d_j \in \{0,1\}^*$. Assume there is for all $0 \leq j \leq n$ the following holds:
1. $d_j \neq \epsilon$
2. $d_j^\infty \neq c_{j+1}d_{j+1}^\infty$

Equally assume $d_n^\infty \neq c_0d_0^\infty$. Then there holds:

$$w \prod_{i=0}^{\infty} \prod_{j=0}^{n} c_j d_i^j \triangleright \Pi$$

Proof. A transducer $R$ can be constructed that transforms the left-hand side into the right-hand side. The starting word $w$ may be transducer to a suitable prefix of $\Pi$. The transducer may detect every transition from $\ldots d_j d_j \ldots$ to $c_{j+1}d_{j+1} \ldots$ as the two words are not equal at some position. Upon detecting a switch in the input a “1” may be given as output and for each subsequent $d$ a “0”. \hfill \Box

The subsequent lemmas will show that Theorem 9.8 can be applied to any non-periodic transduct of $\Pi$.

**Lemma 9.9.** Let $w \prod_{i=0}^{\infty} \prod_{j=0}^{n} c_j d_i^j$ be a non-eventually periodic word for $n \geq 0$ and some $w, c_j, d_j \in \{0,1\}^*$. Then it may be assumed that for all $0 \leq j < n$ it holds that:

$$d_j \neq c_{j+1}d_{j+1}^\infty$$

Equally it holds that $d_n \neq c_0d_0^\infty$. Then it may be assumed that for all $0 \leq j < n$ it holds that:

$$d_j \neq c_{j+1}d_{j+1}^\infty$$

Proof. Suppose there is some $k$ such that $d_k = \epsilon$. Suppose $n = 0$, then the word would be periodic, so assume $n \geq 1$. Then replace $c_{k+1}$ with $c_kc_{k+1}$ and the word may be written as

$$w \prod_{i=0}^{\infty} \prod_{j=0}^{n} c_j d_i^j = w \prod_{i=0}^{\infty} \prod_{j=0}^{n-1} c_j^' d_j^i$$

for appropriate $c_j^', d_j^i \in \{0,1\}^*$. \hfill \Box

The subsequent lemma has been called the “removing confusion lemma” in [EHK11].

**Lemma 9.10.** Let $w \prod_{i=0}^{\infty} \prod_{j=0}^{n} c_j d_i^j$ be a non-eventually periodic word for $n \geq 0$ and some $w, c_j \in \{0,1\}^+$ and $d_j \in \{0,1\}^+$. Then it may be assumed that for all $0 \leq j < n$ it holds that:

$$d_j \neq c_{j+1}d_{j+1}^\infty$$

Equally it holds that $d_n \neq c_0d_0^\infty$.

Proof. Suppose that for a certain $j$ it holds:

$$d_j \neq c_{j+1}d_{j+1}^\infty$$

Suppose $n = 0$, then the above would read:

$$d_0 \neq c_0d_0^\infty$$

This would suggest:

$$c_0d_0 \neq c_0d_0^\infty$$

So surely $c_0d_0 = d_0c_0$. Then

$$w \prod_{i=0}^{\infty} c_0 d_i^0$$
would be periodic, so assume $n \geq 1$. Let $r$ be the largest $r \in \mathbb{N}_{>0}$ such that for some $x \in \Sigma^+$:

\[ d_j = x^r \]

There is some $v \in \mathbb{N}$ such that

\[ c_{j+1}^* = x^v c_{j+1} \]

where $c_{j+1}^*$ is the appropriate suffix of $c_{j+1}$ such that $x$ is no prefix of $c_{j+1}^*$. Conclude that $c_{j+1}^*$ is a prefix of $x$: $x = c_{j+1}^* b$ holds for some $b \in \Sigma^*$. But then it is clear that $b$ is a prefix of $d_{j+1}$. Summarizing this yields:

\[ c_{j+1}^* b = x \]

\[ d_{j+1} = b d_{j+1}^* \]

where $d_{j+1}^*$ is the appropriate suffix of $d_{j+1}$. Then it holds that:

\[ d_j^\infty = c_{j+1} d_{j+1}^\infty \]

\[ x^\infty = c_{j+1} (b d_{j+1}^*)^\infty \]

\[ = x^v c_{j+1}^* b (d_{j+1}^*)^\infty \]

\[ = x^{v+1} (d_{j+1}^*)^\infty \]

\[ = (d_{j+1}^*)^\infty \]

Recall that $c_{j+1}^* b = x$ and conclude that $d_{j+1} = b x^s c_{j+1}^*$ for some $s \in \mathbb{N}$. Combining the above yields:

\[ c_j d_j^k c_{j+1} d_{j+1}^k c_{j+2} = c_j x^{kr} x^{v_j^*} b x^{k(s+1) - 1} c_{j+1}^* c_{j+2} \]

\[ = c_j x^{kr+v_j^*} x^{k(s+1)} c_{j+1}^* c_{j+2} \]

\[ = c_j x^{k(s+r+1) + v_j^*} c_{j+1}^* c_{j+2} \]

Renaming appropriately shows that the word can be written as

\[ T(\Pi) = w \prod_{i=0}^{n-1} \prod_{j=0}^{c_j d_j^i} \]

with $n \geq 1$. □

10. ON THE FIBONACCI SEQUENCE

Denote $a \not\triangleright b$ to be the negation of $a \triangleright b$. The following construction has been introduced by [EHK11] and has appropriately been called an infinite descending chain:

\[
\begin{array}{c}
\ldots \\
\triangleright 10^{2^0} 10^{2^1} 10^{2^{12}} 10^{2^{16}} 10^{2^{20}} 10^{2^{24}} \\
\triangleright 10^{2^0} 10^{2^2} 10^{2^{6}} 10^{2^{8}} 10^{2^{12}} \\
\triangleright 10^{2^0} 10^{2^1} 10^{2^{4}} 10^{2^{8}} 10^{2^{16}} \\
\ldots
\end{array}
\]

More formally define:

\[ I_i = \prod_{k=0}^{\infty} 10^{j(2^{i+k})} \]

It holds that for $i \geq 0$

\[ I_i \triangleright I_{i+1} \]

\[ I_{i+1} \not\triangleright I_i \]
This section will now go on to introduce a second infinite descending chain. The construction involves using the Fibonacci sequence:

\[ F_{n+2} = F_n + F_{n+1} \]
\[ F_0 = 0 \]
\[ F_1 = 1 \]

**Lemma 10.1.** Fix \( i \in \mathbb{N}_{>0} \), then there holds:

\[ \prod_{k=0}^{\infty} 10^{F_{ik}} \mathrel{\vartriangleleft} \prod_{k=0}^{\infty} 10^{F_{2ik}} \]

**Proof.** Figure 9 shows the appropriate transducer. It removes every second instance of \( 10^n \) and leaves the others untouched. \( \square \)

\[ \begin{array}{c}
0|0 \\
0|\epsilon
\end{array} \]

\[ \xrightarrow{\epsilon} q_0 \]

\[ \xrightarrow{1} q_1 \]

\[ \xrightarrow{1} q_0 \]

\[ \begin{array}{c}
1|\epsilon \\
0|\epsilon
\end{array} \]

**Figure 9.** \( \prod_{k=0}^{\infty} 10^{F_{ik}} \mathrel{\vartriangleleft} \prod_{k=0}^{\infty} 10^{F_{2ik}} \)

**Theorem 10.2.** Fix \( i \in \mathbb{N}_{>0} \), then there holds:

\[ \prod_{k=0}^{\infty} 10^{F_{2ik}} \not\mathrel{\vartriangleleft} \prod_{k=0}^{\infty} 10^{F_{ik}} \]

**Proof.** The Fibonacci sequence \( \{ F_k \}_{k \in \mathbb{N}} \) is period modulo any positive integer, as shown in [Wal60]. Then the sequences \( \{ F_{ik} \}_{k \in \mathbb{N}} \) and \( \{ F_{2ik} \}_{k \in \mathbb{N}} \) will also be periodic modulo every integer. From Theorem 9.7 follows that for any transducer \( T = (Q, \{0, 1\}, \delta, q_0, \Delta, \lambda) \) there are some \( c_j, d_j \in \Delta^* \) and \( n, m \in \mathbb{N} \) such that

\[ T(\prod_{k=0}^{\infty} 10^{F_{2ik}}) = w \prod_{i=0}^{n} \prod_{j=0}^{n} c_j d_{i,j}^{a_{i,j}} \]

with

\[ a_{i,j} = \frac{F_{2k(m+j)+ip} - F_{2k(m+j)}}{Z} \]

where \( Z \) is the least common multiple of all zero-loops in \( T \) and \( p \) the period of \( \{ F_{2ik} \mod Z \}_{k \in \mathbb{N}} \). In accordance with the proof in Theorem 9.8, assume that \( d_j \neq \epsilon \) for \( 0 \leq j \leq n \). Suppose that:

\[ w \prod_{i=0}^{n} \prod_{j=0}^{n} c_j d_{i,j}^{a_{i,j}} = \prod_{k=0}^{\infty} 10^{F_{ik}} \]

Then for the right hand side every factor \( 10^n \epsilon \) occurs at most once for every \( n \in \mathbb{N} \). This implies that every \( d_j \) contains only zeros. It also implies that every \( c_j \) contains at most one one. The claim now is that there can be no \( d_j \) that satisfy the above
equation. If this were true, then the theorem would hold. The proof of the claim follows from the fact that for $0 \leq j \leq n$:

\[
\lim_{k \to \infty} \frac{a_{i,j}}{F_{ik}} = \lim_{k \to \infty} \frac{F_{2k(m+j+ip)} - F_{2k(m+j)}}{ZF_{ik}} = \lim_{k \to \infty} \frac{F_{2k(m+j+ip)}}{F_{ik}} = \infty
\]

This shows that the growth of $F_{2ki}$ in terms of $F_{ik}$ is more than linear. The word length of $c_j d_j F_{2ki}$ is a linear function for argument $F_{2ki}$, so it cannot adjust for the more-than-linear growth of $F_{2ki}$ over $F_{ik}$.  

So then $\prod_{k=0}^{\infty} 10^{F_{ik}}$ is an infinite descending chain:

\[
\prod_{k=0}^{\infty} 10^{F_{ik}} \triangleright \prod_{k=0}^{\infty} 10^{F_{2ki}} \quad \text{and} \quad \prod_{k=0}^{\infty} 10^{F_{2ki}} \triangleright \prod_{k=0}^{\infty} 10^{F_{ik}}
\]

11. Acknowledgments

First and foremost I would like to thank my thesis supervisor Robbert Fokkink for all the effort and pastoral support. He has been the best supervisor I could ever imagine. Further thanks goes to Michel Dekking, Joerg Endrullis, Wan Fokkink, Dimitri Hendriks and Jan Willem Klop for additional supervision and support.

REFERENCES

5Special thanks to Joerg Endrullis for providing useful comments regarding the proof.
APPENDIX A. Period doubling sequence

Let the generalization of Toeplitz substitution \( k \) and \( v_2 \) be with \( p \) a prime:

**Definition A.1.**

\[
\begin{align*}
k_p(0) &= 0^{p-1}1 \\
k_p(1) &= 0^{p-1}0 \\
v_p(n) &= \{\max_b \ p^b | n\} \mod 2
\end{align*}
\]

**Lemma A.2.** For \( n \in \mathbb{N}_{>0} \) and \( p \) prime holds that:

\[
\{v_p(n)\}_{n \in \mathbb{N}_{>0}} = k_p^\infty(0)
\]

*Proof.* We shall prove this claim by showing the recurrence relations are the same for both the substitution and the function. From the definition of \( v_p(n) \) follows that for all \( 0 < c < p^2 \)

\[
\begin{align*}
v_p(c) &= v_p(c + p^2) = v_p(c)
\end{align*}
\]

It is clear that

\[
k_p^m(0) = v_p(1), v_p(2), \ldots, v_p(p^m)
\]
holds for \( m = 2 \) and \( m = 1 \). We note that

\[
\begin{align*}
k_p^2(0) &= v_p(1), v_p(2), \ldots, v_p(p^2 - 1), 0 \\
k_p^2(1) &= v_p(1), v_p(2), \ldots, v_p(p^2 - 1), 1
\end{align*}
\]

and it follows that both sequences have the same recurrence relations. \(\square\)

**Lemma A.3.** Let \( p \) be a prime. Then for \(-p^m < a < p^m\) with \( a' \neq 0 \) and all \( n \in \mathbb{N}_{>0} \) holds that:

\[
v_p(n2^m + a) = v_p(n2^m - a) = v_p(|a|)
\]

*Proof.* Follows from the base-\( p \) expansion of \( a + n2^m \). \(\square\)

**Lemma A.4.** Let \( k_p \) denote the Toeplitz substitution with prime \( p \) over the \( \{0,1\} \) alphabet. Let \( 0 < a < p^m - 1 \) with \( a, m \in \mathbb{N}_{>0} \) fixed. Then it holds:

\[
\rho^\infty_{a+1,k_p}(v_p(a)) = \{v_p(a + n(2^m - 1))\}_{n \in \mathbb{N}}
\]

*Proof.* First we will show that the first \( p^m \) symbols of both sides are matching. After that, we will show a recurrence relation that holds for both sides. Together with the first step this will complete the proof.

Note that \( \rho^\infty_{a+1,k_p} \) is a substitution prolongable on \( v_p(a) \). The following holds:

\[
\begin{align*}
k^m(0) &= v_p(1), v_p(2), \ldots, v_p(p^m) \\
k^m(1) &= v_p(2^m + 1), v_p(2^m + 2), \ldots, v_p(2^m + 1)
\end{align*}
\]

It follows from lemma A.3:

\[
\begin{align*}
k^m(0) &= v_p(1), v_p(2), \ldots, v_p(p^m - 1), v_p(p^m) \\
k^m(1) &= v_p(2^m + 1), v_p(2^m + 2), \ldots, v_p(p^m + 1), v_p(p^m + 1) \\
&= v_p(1), v_p(2), \ldots, v_p(p^m - 1), v_p(p^m + 1) \\
k^m(v_p(a)) &= v_p(1), v_p(2), \ldots, v_p(p^m - 1), v_p(ap^m)
\end{align*}
\]

We note that \( k^m_p(v_p(a)) \) only depends on \( a \) in the \( p^m \)-th (final) entry. It is important for the second step of the proof to see that if \( m \) is even it holds \( v_p(ap^m) = v_p(a) \).
and likewise when \( m \) odd \( v_p(ap^m) = 1 - v_p(a) \). We may rotate \( k_p^m(v_p(a)) \) to obtain \( \rho_{a+1,k_p^m}(v_p(a)) \) and use lemma A.3 to rewrite:

\[
\rho_{a+1,k_p^m}(v_p(a)) = v_p(p^m - a), \ldots, v_p(ap^m), v_p(1), \ldots, v_p(p^m - a - 1)
\]

\[
= v_p(a), \ldots, v_p(a + (a + 1)(p^m - 1)), v_p(a + (a + 1)(p^m - 1)), \ldots, v_p(a + (p^m - 1)(p^m - 1))
\]

This completes the first step of the proof. Suppose \( m \) is even. Let \( 0 < c < p^m - 1 \) with \( c \neq a \) and substitute \( n = c + rp^m \) for \( r \in \mathbb{N} \), then it follows by lemma A.3 that:

\[
v_p(a + (p^m - 1)n) = v_p(a + (p^m - 1)(c + rp^m))
\]

\[
= v_p(a + c(p^m - 1) + (p^m - 1)rp^m)
\]

\[
= v_p(a + c(p^m - 1))
\]

Which shows that for \( c \neq a \), the \( c + p^m r \)-th entry of the sequence. Now suppose \( m \) is even and \( c = a \). Then we find:

\[
v_p(a + (p^m - 1)n) = v_p(a + (p^m - 1)(c + rp^m))
\]

\[
= v_p(a + (p^m - 1)(a + rp^m))
\]

\[
= v_p(p^m(a + (p^m - 1)r))
\]

\[
= v_p(a + (p^m - 1)r))
\]

So for \( c = a \), we find that the \( a + p^m r \)-th entry of \( \{v_p(a + n(p^m - 1))\}_{n \in \mathbb{N}} \) is actually equal to the \( r \)-th entry of the sequence. Using \( m \) even we find:

\[
\rho_{a+1,k_p^m}(0) = v_p(p^m - a), \ldots, v_p(p^m - 1), 0, v_p(1), \ldots, v_p(p^m - a - 1)
\]

\[
\rho_{a+1,k_p^m}(1) = v_p(p^m - a), \ldots, v_p(p^m - 1), 1, v_p(1), \ldots, v_p(p^m - a - 1)
\]

and we conclude that indeed the \( r \)-th entry of the fixed point of the substitution is equal to its \( a + p^m r \)-th entry. Both sequences have the same recurrence rules for \( m \) is even. Now consider \( m \) odd. We still find that for \( c \neq a \):

\[
v_p(a + (p^m - 1)n) = v_p(a + c(p^m - 1))
\]

However for \( c = a \) it follows:

\[
v_p(a + (p^m - 1)n) = v_p(a + (p^m - 1)(c + rp^m))
\]

\[
= v_p(a + (p^m - 1)(a + rp^m))
\]

\[
= v_p(p^m(a + (p^m - 1)r))
\]

\[
= 1 - v_p(a + (p^m - 1)r))
\]

Equally we find:

\[
\rho_{a+1,k_p^m}(0) = v_p(p^m - a), \ldots, v_p(p^m - 1), 1, v_p(1), \ldots, v_p(p^m - a - 1)
\]

\[
\rho_{a+1,k_p^m}(1) = v_p(p^m - a), \ldots, v_p(p^m - 1), 0, v_p(1), \ldots, v_p(p^m - a - 1)
\]

and the result follows. \( \square \)

**Theorem A.5.** Let \( a, b \in \mathbb{N}_{>0} \) be such that \( 0 < a < b \), \( p \nmid b \) and \( p \) a prime, then there are some \( c, m \in \mathbb{N}_{>0} \) such that

\[
\{v_p(a + bn)\}_{n \in \mathbb{N}} = \rho_{ac+1,k_p^m}(v_p(ac))
\]

**Proof.** Suppose \( c, m \) are such that \( cb = p^m - 1 \). Then we know \( p \nmid c \) and invoke lemma A.4 to write:

\[
\{v_p(a + bn)\}_{n \in \mathbb{N}} = \{v_p(ca + cbm)\}_{n \in \mathbb{N}}
\]

\[
= (\rho_{ac+1,k_p^m})^\infty(v_p(ac))
\]
Suppose $m \rho$ the rotated substitution $m$ rules. From the recurrence rules follows that the first 2

So then $b$ does divide $p^s - 1$, which is an contradiction.

**Theorem A.6.** Let $\rho_{q+1,k_p}$ be a rotated Toeplitz substitution as noted in section 3 with $0 < q < (p^m - 1)$, $m \in \mathbb{N}_{>0}$ and $p$ a prime. Then for every $r \in \mathbb{Z}\setminus\{0\}$ and $l \in \mathbb{N}_{>0}$ it holds

$$\rho_{q+1,k_p} (\{v_p(\frac{r}{p^l - 1} + n)\})^{n\in\mathbb{N}} = \{v_p(\frac{p^m r}{p^l - 1} - q + n)\})^{n\in\mathbb{N}}$$

**Proof.** It will be shown that both sides of the equation have the same recurrence rules. From the recurrence rules follows that the first $2^m$ letters of both sides are the same, completing the proof. But first recall from section 3 the construction of the rotated substitution $\rho_{q+1,k_p}$:

- $k_p^m(0) = v_p(1), v_p(2), v_p(3), \ldots, v_p(p^m - 1), v_p(p^m)$
- $k_p^m(1) = v_p(1), v_p(2), v_p(3), \ldots, v_p(p^m - 1), 1 - v_p(p^m)$
- $\rho_{q+1,k_p}^m(0) = v_p(p^m - q), v_p(p^m - q + 1), \ldots, v_p(p^m), v_p(1), \ldots, v_p(p^m - q - 1)$
- $\rho_{q+1,k_p}^m(1) = v_p(p^m - q), v_p(p^m - q + 1), \ldots, 1 - v_p(p^m), v_p(1), \ldots, v_p(p^m - q - 1)$

Suppose $m$ is even and consider $n = q + ip^m$ with $i \in \mathbb{N}$. It holds:

$$v_p(\frac{p^m r}{p^l - 1} - q + n) = v_p(\frac{p^m r}{p^l - 1} - q + q + ip^m)$$

$$= v_p(p^m(r + i(p^l - 1)))$$

$$= v_p(r + i(p^l - 1))$$

$$= v_p(\frac{r}{p^l - 1} + i)$$

Now consider the left hand side of the statement and denote

$$\rho_{q+1,k_p} (\{v_p(\frac{r}{p^l - 1} + i)\}) = \rho_0, \rho_1, \ldots, \rho_{p^m - 1}$$

then $\rho_q = v_p(\frac{r}{p^l - 1} + i)$. Now if $m$ were odd, then $\rho_q = 1 - v_p(\frac{r}{p^l - 1} + i)$ and:

$$v_p(\frac{p^m r}{p^l - 1} - q + n) = 1 - v_p(\frac{r}{p^l - 1} + i)$$

So for $n = q + ip^m$ with $i \in \mathbb{N}$ the equation-to-prove holds. Now consider $n = s + ip^m$ with $s \neq q$ and $0 \leq s < p^m$. It follows that $|s - q| < p^m - 1$, which is to be used in the second to final step of the derivation below:

$$v_p(\frac{p^m r}{p^l - 1} - q + n) = v_p(\frac{p^m r}{p^l - 1} - q + s + ip^m)$$

$$= v_p(p^m r + (p^l - 1)(s - q + ip^m))$$

$$= v_p(p^m(r + (p^l - 1)i) + (p^l - 1)(s - q))$$

$$= v_p(|s - q|)$$
It is clear that for $n = s + ip^m$ with $s \neq q$ and $0 \leq s < p^m$ the expression is dependent on $s$ and independent of $i$. In fact, the expansion of $\rho_{q+1,k}^m$ given at the start of the proof now shows the two sides are equal. □
